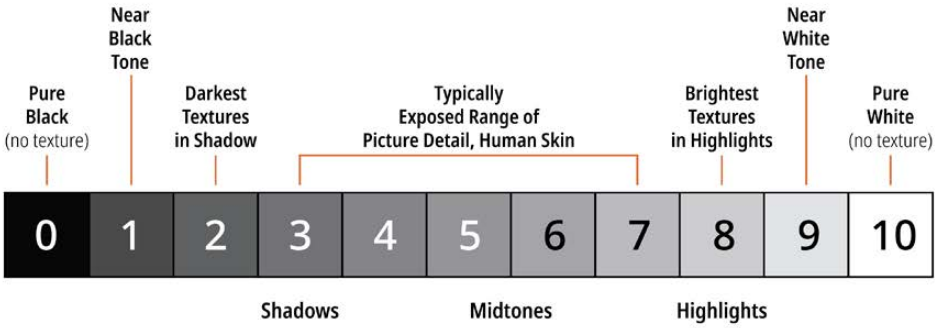
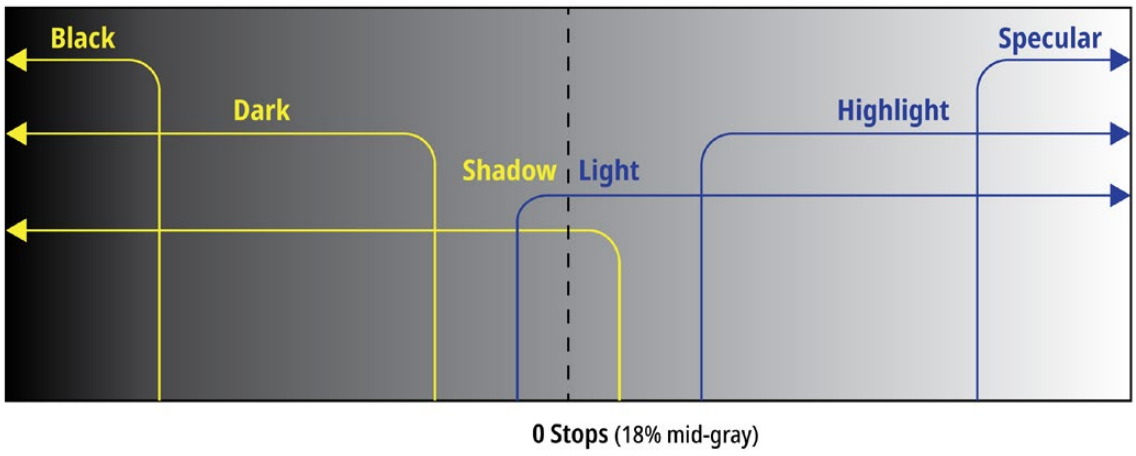
After you've made whatever initial global adjustments you want, you can optionally make more tonally-specific adjustments to the image via the Zone-based color and contrast controls to the left. These divide the image into multiple overlapping "zones," which are somewhat similar in principal to Ansel Adams' zone system, which divides images into tonally-specific regions based on image luminance, from pure black, through progressively lighter shadows, to 18% gray as the middle value centering the midtones of most images, and then up through progressively lighter highlights on the way to the last zone of pure white.



Simplified illustration of Ansel Adams' zone system

While Adams' zone system was meant to teach people how to think about using the available range of the photographic medium when exposing images, the zones of the HDR palette let you put this concept into practice by allowing you to make tonally-specific Color Balance, Saturation, and Exposure adjustments that only affect the range of shadows or highlights that fall within that zone.

Using the default preset, the shadows of your image are divided into overlapping Shadow, Dark, and Black zones, while the highlights of your image are divided into separate overlapping zones for Light, Highlight, and Specular ranges. The chart below illustrates the relationship of these zones to one another.



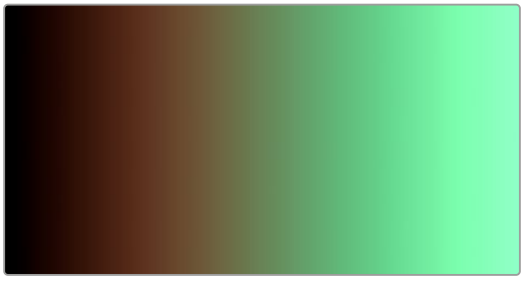
Approximation of the overlapping zones in the HDR palette that can be individually adjusted

NOTE: All of the examples in this section have Timeline to Output Tone Mapping set to None, to keep the ramp gradient linear for purposes of this explanation.

Zone-Based Color Adjustments

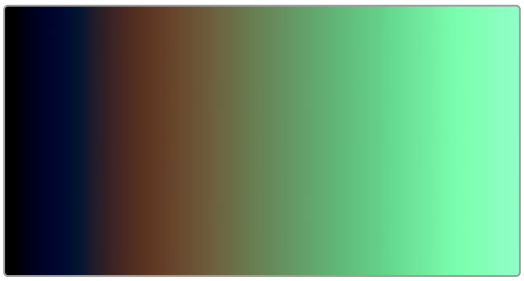
Understanding how adjustments made using these overlapping zones interact with one another is key to knowing what you can do using the HDR palette. Keep in mind that every zone is customizable, but here's how the default zone definitions work to let you make detailed image adjustments. For clarity, Zone adjustments are shown made to a linear ramp gradient image, to demonstrate exactly what tonal portion of each image is affected by each control.

- The Light and Shadow zones are the most broadly defined zones. Together, they cover the entire tonal range of your image. They softly overlap one another by two stops at the center of the tonal range (50% gray or 18% exposure); this is where adjustments made to Light mix together with adjustments made to Shadow, resulting in both adjustments softly blending together. Making exposure adjustments to these two zones lets you manipulate overall image contrast by selectively compressing/expanding contrast in the shadows and/or highlights relative to one another. Using the color controls lets you make broad color adjustments to the upper (highlights) and/or lower (shadows) range of image tonality.



Color adjustments to a ramp gradient show the Light (tinted green) and Shadow (tinted orange) zones

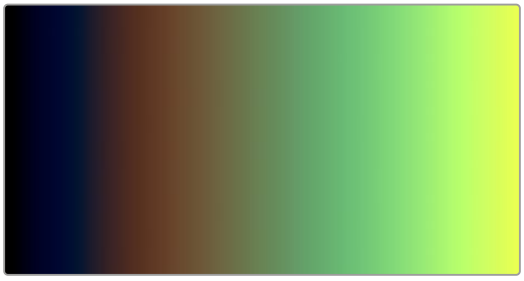
- The Dark and Black zones overlap two progressively lower luminance ranges of the Shadow zone. Dark is useful for adjusting the color or contrast of the deeper shadows, while Black is useful as a trim that lets you manipulate the very darkest parts of an image. All adjustments you make to Dark are mixed with any adjustments made to Shadow, and all adjustments made to Black are mixed with the adjustments made to Dark and Shadow. In this way, all color adjustments you make to overlapping Shadow zones mix smoothly together to produce the final result, as seen in the following ramp gradient.



Color adjustments to a ramp gradient show the Dark (tinted blue) overlapping the Shadow (tinted orange) zone

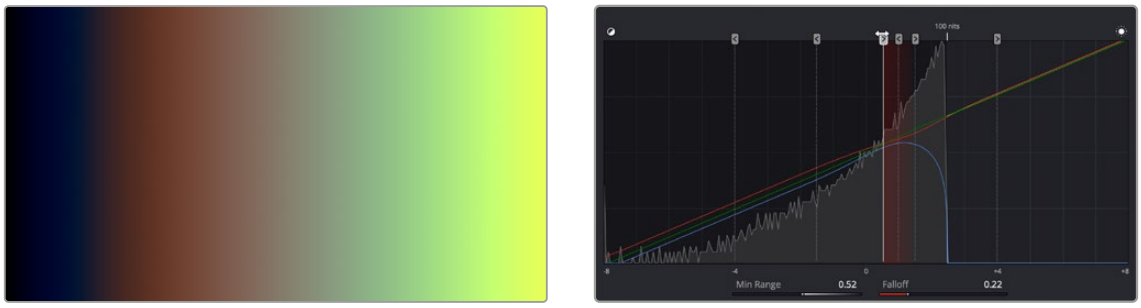
- The Highlight and Specular zones overlap two progressively brighter luminance ranges of the Light zone. Highlight lets you adjust the color and/or contrast of the brightest highlights, while

Specular is useful as a trim that lets you manipulate the very brightest highlights of an image. All adjustments you make to Highlight are mixed with any adjustments made to Light, and all adjustments made to Specular are mixed with the adjustments made to Highlight and Light. In this way, all color adjustments you make to overlapping Highlight zones mix smoothly together to produce the final result, as seen in the following ramp gradient.



Color adjustments to a ramp gradient show the Highlight (tinted yellow) overlapping the Light (tinted green) zone.

As you can see, each one of these zones allow the specific adjustment of whichever parts of the image fall within the luminance range of that zone (as defined on the Zones panel), while providing control over how smoothly one adjustment fades into the next, to prevent unwanted contouring. As you make adjustments to the Range and Falloff of each zone using the different sets of zone controls, they work together to smoothly manipulate the contrast and color of the image, similarly to if you were using a more precise and constrained version of the Custom Curves. In fact, you can see the actual adjustment you're making by exposing the Zone graph.



(Left) Raising the Range of the Light zone to expand the Shadow zone's range of influence, (Right) The same adjustment seen in the Zone graph

Working this way allows a tremendous specificity of adjustment, without the need to use curves or qualifiers. For example, zone-specific Color Balance controls allow you to grade the highlights and shadows separately using the Shadow and Light zone controls to quickly create a warm/cool split lighting effect. This makes the creation of dynamic grades more efficient and more creative.

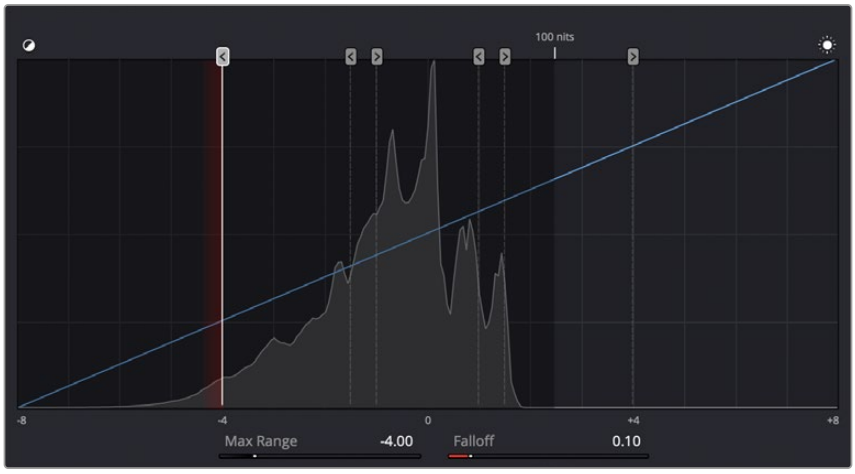
(Left) The original image, (Right) Using the HDR palette to warm the highlights and cool the shadows (exaggerated for print)

In this next example, the Dark zone's Color Balance control is used to add a splash of green to the darker shadows of the image, while the Black control is used to neutralize this green in the very blackest shadows.

(Left) The original image, (Right) Using the HDR palette to add green to a narrow range of shadows

Zone-Based Exposure Adjustments

Each zone has its own Exposure control that allows you to stretch image contrast from that zone's Min or Max range boundary either down towards the shadows, or up towards the highlights. As seen on the Zone graph (found on the Zone panel), exposure adjustments are made on a scale measured in stops, to provide a more photographic experience when grading wide dynamic range material.



The scale of the Zone graph shows you the shadow and highlight ranges, in stops, relative to 0 representing 18 percent photographic gray

On this scale, 0 stops corresponds to photographic 18% gray, at the center of each image's tonal range. Shadows then fall to the left over -8 stops, while highlights fall to the right over +8 stops, where each stop represents either twice the amount of light (stopping up) or half the amount of light (stopping down).

In conjunction with Resolve Color Management, this range is designed to accommodate any SDR or HDR range you'll be mastering to. All HDR palette controls are designed to accommodate up to 16 stops of exposure. By comparison, most modern digital cinema cameras claim to be able to capture somewhere between 13-19 stops of dynamic range, while a white paper from the ASC states that modern film negatives are capable of capturing 14 stops of dynamic range.

Unlike the Lift/Gamma/Gain or Log master level controls, the Exposure adjustment of each zone starts at a specific boundary of image tonality, and stretches all the way out through the highlights or shadows, through the maximum or minimum signal level allowable. Since Shadow and Light are the two zones that are centered on the midtones of the image, they're the best zones for seeing how

this works. Because of this, these are also probably the first two zones you'll want to adjust if you're making more specific exposure changes to the image.

Using the default preset, Shadow exposure adjustments affects everything in the image from stop 1 down through absolute black.

(Left) The original image, (Right) Darkening all shadows by lowering the Shadow exposure adjustment

Meanwhile, Light exposure adjustments affect everything in the image from -1 stops all the way through maximum white.

(Left) The original image, (Right) Lightening all highlights by raising the Light exposure adjustment

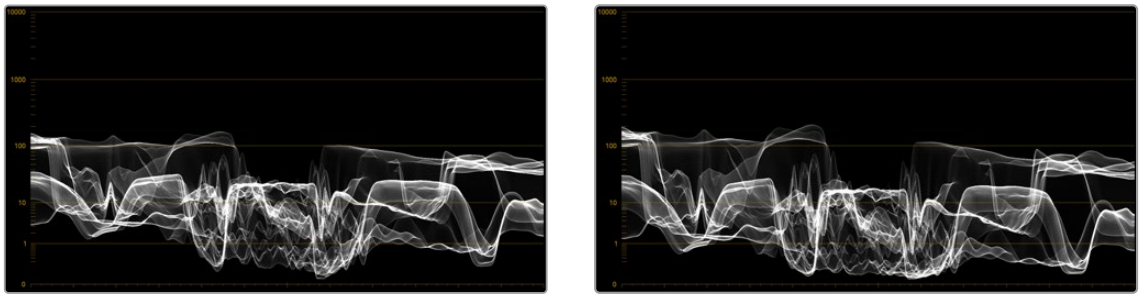
This ability to make open-ended adjustments to image contrast in different overlapping ranges of shadow and highlight tonality makes these controls uniquely suitable for HDR grading, while also being completely suitable when grading at SDR levels. Also, keep in mind that all contrast adjustments in the HDR palette keep saturation constant as contrast increases or decreases.

This is particularly useful when making large contrast adjustments to HDR images, for which a 300 nit expansion of highlight contrast using the Lift/Gamma/Gain or Log controls would create a huge saturation increase. Using the HDR palette to expand highlight contrast keeps image saturation perceptually the same, while offering zone-specific saturation controls that let you choose whether to increase or decrease the saturation falling within that zone.

Exposure adjustments to zones that overlap other zones are smoothly combined to allow targeted contrast adjustments, while making it relatively easy to avoid unwanted artifacts, like contouring or solarizing due to overzealous inversion of the curves caused by these operations.

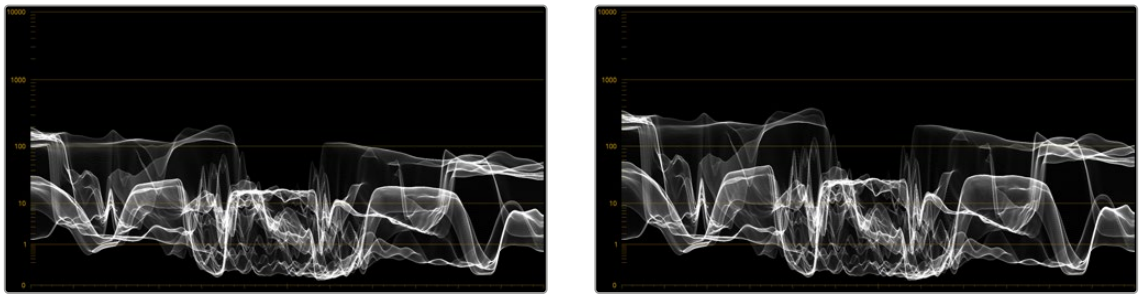
An Example of Zone-Based Exposure Adjustment

To see this in action, let's see what happens when we make some overlapping adjustments to the Light, Highlight, and Specular zones in order to grade some HDR highlights, focusing our attention on the Waveform scope, since it's difficult to see HDR grades in print. Keep in mind that you won't usually be making Zone-based Exposure adjustments by themselves. This example image has had a Contrast/Pivot adjustment to push the midtones and shadows down, to give the shadows greater definition. Then, Black Offset is raised to lift the darkest shadows up just a little bit, so they can breathe. This leaves us with an image that's mostly under 200 nits to begin with. A perfect starting point for us to begin sculpting those highlights.



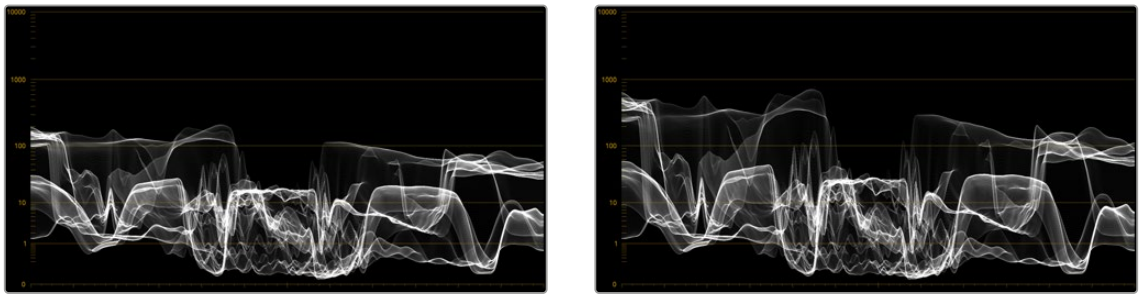
(Left) The original image; (Right) After changing Contrast/Pivot and raising Black Offset

Using the default preset, making an exposure adjustment to the Light zone smoothly raises everything in the source image above -1 stops on the Zone graph. Practically, it's stretching up all levels above 10 nits on the HDR scope. This smoothly boosts the brighter part of the image, while leaving the shadows down where we put them.



(Left) The previous adjustment; (Right) After raising Light Exposure

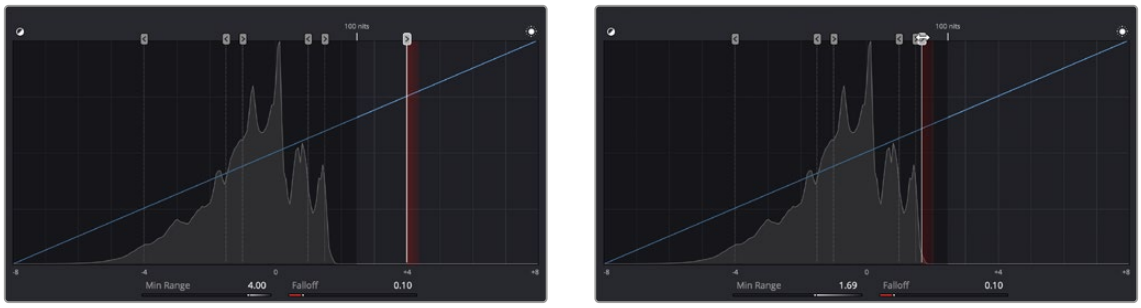
At this point, making an exposure adjustment to the Highlight zone boosts all levels above 1.5 stops on the Zone graph. Again, practically speaking, all levels above 100 nits are being boosted, brightening the top highlights. In the image, you can see that we're creating a greater differentiation between dimmer and brighter highlights in the image, creating highlight contrast with greater detail where once there were simply flat pools of light.



(Left) The previous adjustment; (Right) After raising Highlight Exposure

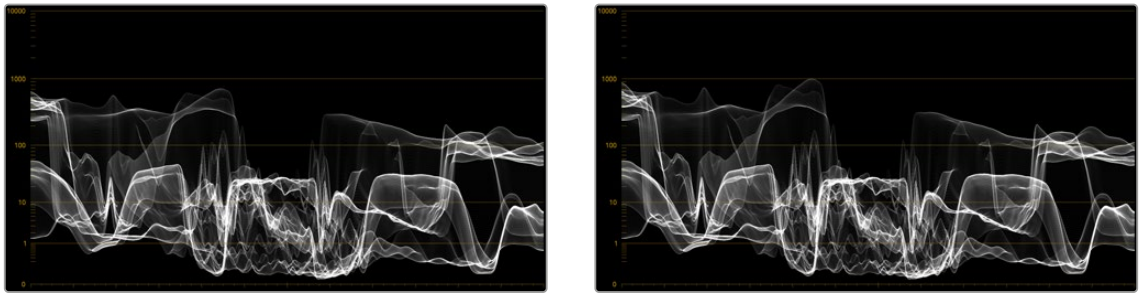
Now, this might be a fine place to stop, but since we're interested in turning the HDR in this image up to 11, we can put the highlights over the top by making one more Exposure adjustment, to the Specular zone. The Specular zone starts at 4 stops and is designed to let you boost or attenuate only the very brightest, hardest highlights, likely corresponding to specular details such as chrome reflections, eye glints, and directly photographed light sources. You won't always use this control, but it's useful to know about.

In this example, the default Specular Zone Min Range control is outside of the available image data in the image (seen as the right edge of the histogram in the Zone graph), so making adjustments with this control won't do anything. However, dragging the Min Range control to intersect the end of the histogram will allow these controls to affect the very brightest pixels in the image.



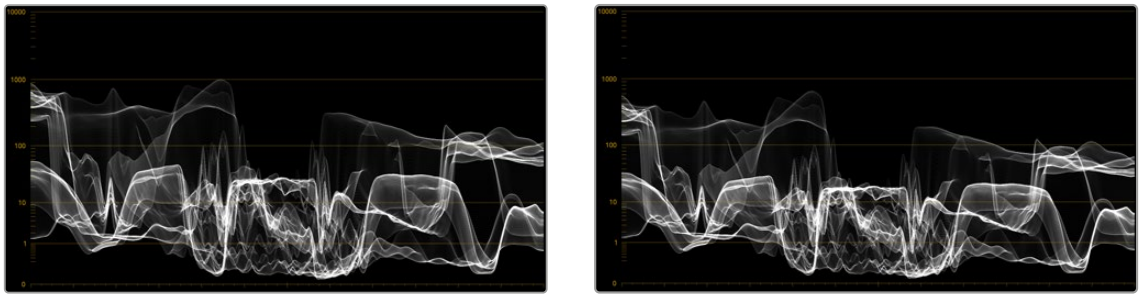
(Left) The original distribution of zones in the Zone Graph; (Right) Dragging the Specular Min Range handle to intersect the brightest highlights in the image histogram, to allow the Specular controls to affect that part of the image

Now, the Specular Exposure control lets us push the very brightest pixels of our image up, further differentiating them from the other highlights, and widening the audience's sensation of highlight contrast.



(Left) The previous adjustment; (Right) After raising Specular Exposure to bring the very brightest highlights to 1000 nits

Now, having selectively boosted the Highlight and Specular zones, you might decide that you like the differentiation that's been created among different brightnesses of highlights, but the overall highlights are too bright. This is easily fixed by lowering the Light zone's Exposure adjustment. As a result of this one adjustment, all of the highlights are scaled down, while the adjustments you've made to the Highlight and Specular zones maintain a relative influence on the parts of the image they're brightening. The Shadow, Dark, and Black controls work similarly, but for the shadows.



(Left) The previous adjustment; (Right) After lowering Light Exposure, all levels smoothly scale down to reduce the brightness of the highlights while keeping the differentiation you've created with the Highlight and Specular controls.

Now that you've seen how all overlapping Zone adjustments work together to create a seamless adjustment, it's time to look at the Zone controls in more detail.

Zone Controls

Each individual zone also has controls for Color Balance and Saturation, which let you make focused adjustments that fall within specific ranges of image tonality, all without needing to use a qualifier. Using all of these zones together, you can make fast, precise, and smooth adjustments to the image that feel incredibly natural. Despite the name of the palette, this allows careful adjustment of SDR images, as well as creative adjustment of the spectacular range of highlights that HDR enables. There are also Range and Falloff controls to the left and right of each cluster of controls that let you redefine each zone's area of influence, even if the Zone graph is hidden.

The Shadow and Light zone controls next to one another; you can see the Min and Max indicators, along with the Range value (in stops) at the upper left of each group of controls.

- **Range indicator:** An icon and value at the upper-right-hand corner of each zone control cluster shows that zone's range. A numeric value shows the range value, which is the Luminance level of image tonality at which that zone's adjustment begins. This value is expressed in stops, while an icon shows you whether it's a maximum range (affecting shadows) or a minimum range (affecting highlights).

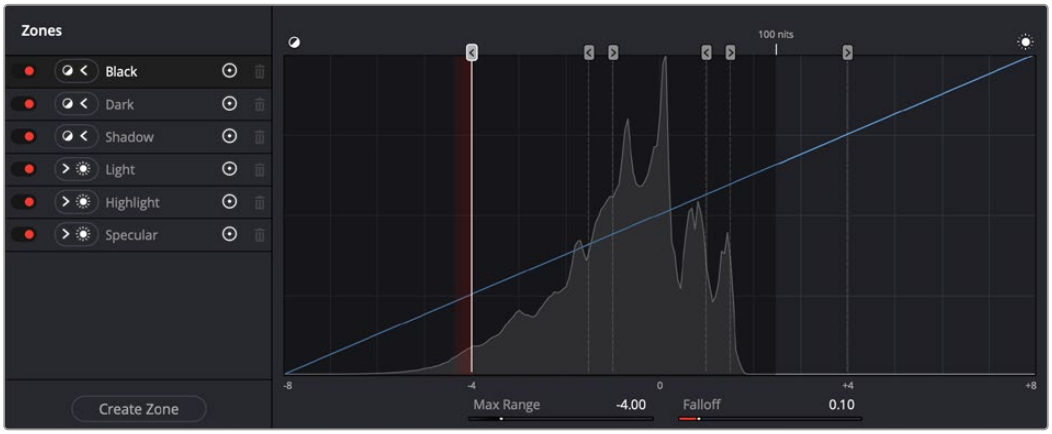
  Clicking the icon shows a temporary preview in the Viewer of which parts of the image will be affected by the controls of that zone. Affected areas appear in full color, while unaffected areas appear black.

- **Zone-specific Color Balance:** A color balance control lets you readjust the relative strength of the red, green, and blue channels within the current zone of image tonality.
- **Zone-specific Exposure:** Zone-specific Exposure controls work in conjunction with an adjustable pivot that defines the Luminance level that each exposure adjustment starts from. To accommodate both shadow and highlight adjustments, there are two kinds of pivots, labeled Maximum and Minimum range, and indicated using an icon. Max Range controls, such as the Shadow control, start at a maximum value with exposure adjustments stretching image contrast downward towards the shadows. Min Range controls, such as Light, start at a minimum value with exposure adjustments stretching contrast upwards towards the highlights. Each zone also has a falloff that specifies how much of that zone overlaps neighboring zones (starting at the pivot level) in order to blend overlapping adjustments softly enough to prevent contouring.
- **Zone-specific Saturation:** Adjusts the intensity of color within the current zone of image tonality.
- **Min/Max Range:** Defines the level of image tonality at which that zone's adjustment starts. This value is expressed in stops. Identical to the Min or Max Range slider in the Zone panel. Useful for tweaking Range while the Zones graph is hidden.

- **Zone Falloff:** Defines how softly this zone fades into all overlapping zones. Identical to the Falloff slider in the Zone panel, the value is visible in the virtual slider below. Useful for tweaking Falloff while the Zones graph is hidden.
- **Zone-specific Color Balance Values:** Two values expose the current color balance operation numerically. The option menu lets you choose between representing these as X and Y, or as Angle and Strength.

Customizing Zones Using the Zone Panel

Similarly to the controls of the Log palette, how these zones overlap can be adjusted in order to make each zone's controls work best for the tonal distribution of the images in any given scene. Zone overlap is governed by individual pairs of Range and Falloff controls, so you can make precise adjustments no matter what the distribution of tonality is in the image you're grading. All zones are organized and customized using the Zone panel, which is divided into the Zones sidebar to the left, and the Zone graph to the right.



The Zone panel of the HDR palette

The Zone Sidebar

The Zone sidebar show a list of all the zones in the current preset. This list is sorted by range values, with minimum range zones (affecting shadows) appearing at top and maximum range zones (affecting highlights) appearing below. Clicking any zone in the list selects that zone, which also selects that zone's boundary handle in the Zone graph at the right.

Zone sidebar controls:

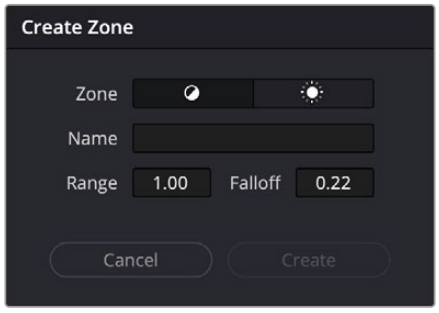
- **Enable Zone toggle:** Toggles let you turn each zone on and off. Disabled zones will not be rendered.
- **Max/Min button:** Defines whether the adjustment of a particular zone affects the image from the current range value and below (Max) or the current range value and higher (Min). This setting is typically used when creating your own custom preset, to define which zones stretch down toward the shadows and which zones stretch up toward the highlights.
- **Show/Hide Zone button:** This button lets you hide sets of zone controls you don't want to adjust any further, leaving more room in the UI and on your control surface for the zones you do want to adjust. For example, if you decide you don't need to use the default Black and Specular zones, you can hide them so that only the Dark, Shadow, Light, and Highlight zones are available to switch among. Zone controls with adjustments made to them continue to affect the image even if the controls are hidden.

- **Delete Zone button:** Deletes that zone. This is primarily useful when you're creating your own zone preset. At the time of this writing, you cannot delete any of the default zones found in the default Zone preset.

  Additionally, you have the option of adding zones, and saving zone presets to create your own custom ways of adjusting the image.

To create a new zone:

1. Open the Zones panel.
2. Click Create Zone, at the bottom of the Zones sidebar.
3. When the Create Zone dialog appears, choose the Zone type you want that zone to have (Dark/Min Zone or Light/Max Zone), enter a Name, and define the Range and Falloff values. Range, Falloff, and Zone type are editable later, so don't worry if you don't set them up perfectly the first time.



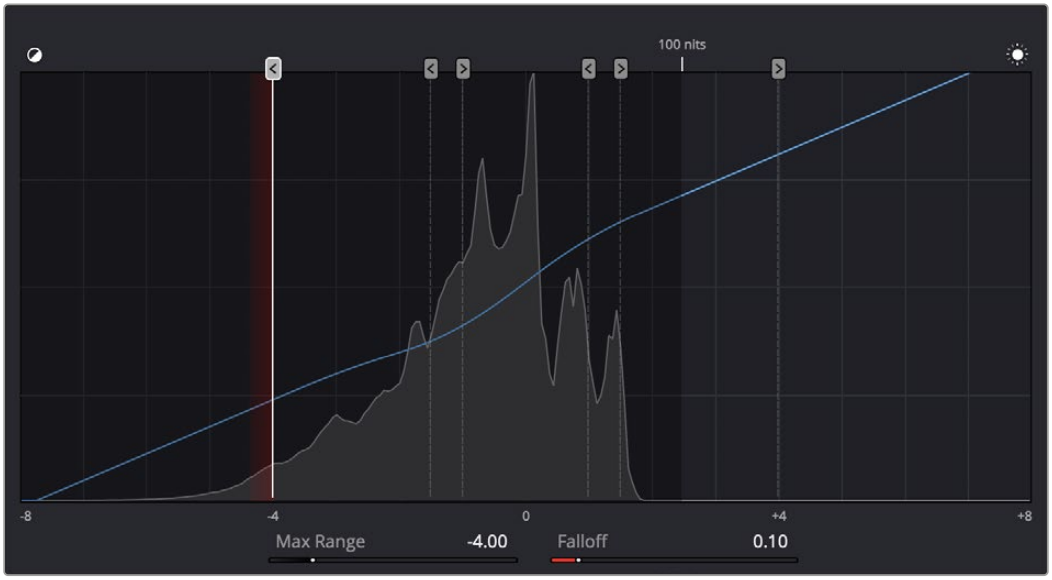
The Create Zone dialog

4. Click Create. That zone appears added to the list, which is sorted in the order in which Range is defined, with Dark Zones appearing at the top, and Light Zones appearing at the bottom.

Zones Graph

The Zone graph is a key component of the HDR palette's use. Along the bottom, a scale in stops shows the range over which the HDR palette operates. At the top, handles let you adjust the editable range boundaries that define the tonal range of each zone's operation, superimposed over a histogram showing the current image as input into the current node. Running through the middle of the Zone graph, a curve shows you all the Global and Tonal color and contrast adjustments being made by the HDR palette in the current grade.

The relationship of the range boundaries with the source image histogram in this graph is extremely important. The range boundary for a particular zone must intersect with the part of the source histogram you want to adjust for the controls of that zone to have any effect. If any zone boundaries lie outside of the histogram, that zone's controls will do nothing. In the screenshot above, the zone's range boundaries all lie inside of the visible histogram, so each zone's controls will make a predictable adjustment to the image data in that part of the histogram.



The Zone graph

In the following screenshot, the Zone graph shows that the Specular zone boundary lies outside of the source histogram for the image, so adjustments made using the Specular controls will have no effect. For this reason, it's a good idea to check that the zone boundaries intersect the parts of the image you want to adjust prior to manipulating the controls, but if you notice that a particular zone's controls aren't having as much of an effect on the image as you'd like, you can always move the zone boundary after the fact to expand the range of the image that's affected by that zone.

The Specular zone boundary lies outside of the source histogram, excluding the Specular controls from affecting the image.

Customizing zone boundaries in this way is one of the most powerful aspects of the HDR palette, but don't worry that you'll be constantly dragging zone boundaries back and forth for every shot you grade. Generally speaking, most well-photographed scenes have similar ranges of image tonality in each shot, so zone boundaries that have been customized for one shot from that scene will likely be good for most clips in that scene. That said, adjusting zone boundaries is another powerful way of tailoring a grade specifically for a clip with a unique range of contrast.

Zone Controls

- **(Min/Max) Range:** Defines the level of image tonality at which that zone's adjustment starts. This value is expressed in stops.
- **Falloff:** Adjusts how softly the adjustment in that zone will blend into the image. A value of 0 results in an immediate transition to the adjustment created in the current zone, with the color adjustment being a sharper effect. Higher values will blend the current zone's adjustment into the image more softly, resulting in a more gentle and seamless transition into the effect.

Customizing and Saving Presets

If you've customized the Zone graph in a way that's potentially useful for other grading situations, you can save a preset of the Zone settings for future use. Saving, recalling, and managing these presets is simple.

Methods of managing presets:

- **To save a preset:** Customize the Zone graph to suit your needs, then choose Save As New Preset from the HDR palette Option menu.
- **To load a preset:** Choose Presets > Name of Preset > Load Preset from the HDR palette Option menu. A new preset will be saved.
- **To update a preset:** Load a preset, make any changes you need to from the Zone graph, and then choose Presets > Name of Preset > Update Preset from the HDR palette Option menu.
- **To delete a preset:** Choose Presets > Name of Preset > Delete Preset from the HDR palette Option menu.
- **To select the default preset:** Choose Default Preset > Name of Preset from the HDR palette Option menu. This preset will now be the one loaded initially into the HDR palette on startup.

Resetting Color and Zone Adjustments

In the HDR palette's Option menu, there's a Reset submenu with three commands, Reset All, Reset Color Adjustments, and Reset Zone Definitions, which are self-explanatory. These are important because, during the course of developing a grade, there will be many times when you'll want to reset your color adjustments without changing how you've customized the Zone graph, or vice versa.

Additionally, each of the visible reset buttons in the GUI can be used with keyboard modifiers to specifically target what to reset. The master reset button in the HDR palette's title bar resets the entire palette when clicked (similar to the Reset All command). However, using keyboard modifiers while clicking this button changes what's reset.

- Hold down Command+Shift while clicking the master reset button to reset only the Zone graph's Range and Falloff controls, without resetting your color adjustments.
- Hold down Command+Option while clicking the master reset button to reset only the color adjustments, while leaving the zones alone.

Both of these modifiers also work with the zone-specific reset controls found in the Wheels panel, letting you reset only the Zone controls or only the Color controls of each specific zone.

Chapter 131

Primary Grading Controls

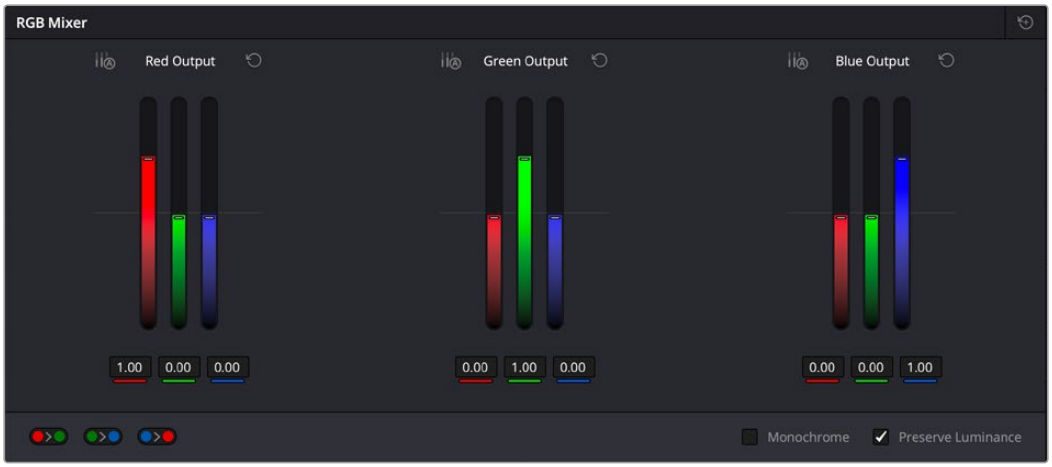
This chapter focuses on the more esoteric adjustments you can make, mixing colors between channels using the RGB Mixer.

Contents

Introduction to the RGB Mixer Palette 2963
Preserve Luminance 2965
Resetting the RGB Mixer 2965
Swap Channels Buttons 2965
Using the RGB Mixer in Monochrome Mode 2966

Introduction to the RGB Mixer Palette

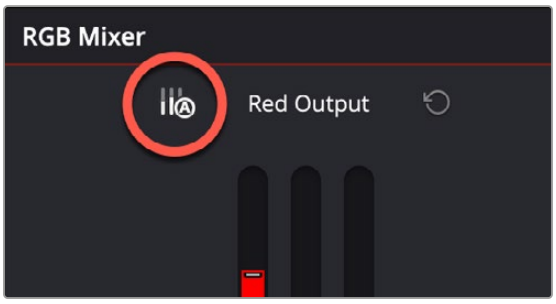
The RGB Mixer palette lets you remix different amounts of image data from one channel to another, and has a wide variety of creative and utilitarian uses. Furthermore, the RGB Mixer can be used either to remix the color channels, or to add different proportions of each color channel into a monochrome image.



RGB Mixer palette

By default, the RGB Mixer palette is set to mix any amount of the Red, Green, and Blue color channels into any of the other channels. Each color channel has a dedicated control group of Red, Green, and Blue sliders that you use to do the mixing, and the default values of these can be seen in the screenshot above.

Each slider has an overall range of –2.00 to +2.00. This means that you also have the option of subtracting any combination of color channel values from a particular channel. For example, you can lower the Red control group's Green slider to –.24 to subtract 24 percent of the Green channel from the Red channel.

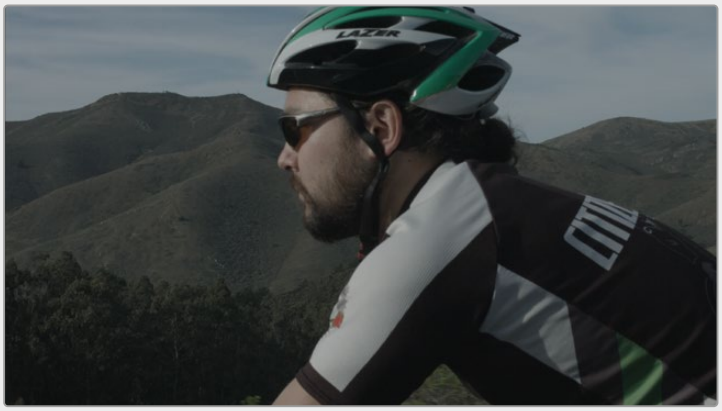


The Auto Normalize control on the Red cμhannel of the RGB Mixer

The RGB Mixer has an additional Auto Normalize control for each channel. These per-channel normalize controls allow for users to adjust channel mixes without affecting overall luminance. When you adjust one color channel, the others will automatically compensate for the change.

Example

The Original image has a cyclist with a green stripe on his helmet:



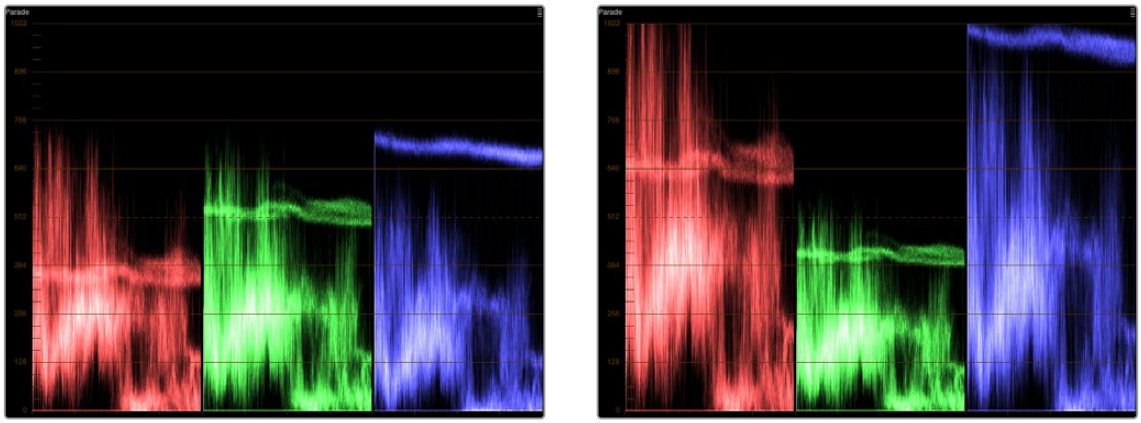
The normal Green channel for the RGB Mixer

Normally reducing the Green channel in the green output adds a magenta cast to the entire image

When Auto Normalize is active, the other two channels compensate for the change in green. Showing the hue change mainly in the green helmet stripe (now turned cyan), with minimal changes to the rest of the image.

Preserve Luminance

With the “Preserve Luminance” checkbox turned on, any channel adjustment you make is prevented from altering the luma of the image by automatically raising or lowering the other two channels to compensate. In the following example, you can see that when “Preserve Luminance” is turned on, lowering the Green control group’s Green slider results in the Red and Blue channels being raised by the same amount (as seen in the Parade scope). Conversely, raising a color channel’s slider ends up lowering the other two channels by the same amount to keep overall image luminosity the same.



The result of an RGB Mixer adjustment with “With luminance level preserved” turned on.
You can see that lowering the green channel slider also raises red and blue.

Resetting the RGB Mixer

Clicking the Reset button at the top right-hand corner of the RGB Mixer resets each slider to its default position, where Red = 1.00 for Red output, Green = 1.00 for Green output, Blue = 1.00 for Blue output, and all other sliders = 0.

Swap Channels Buttons

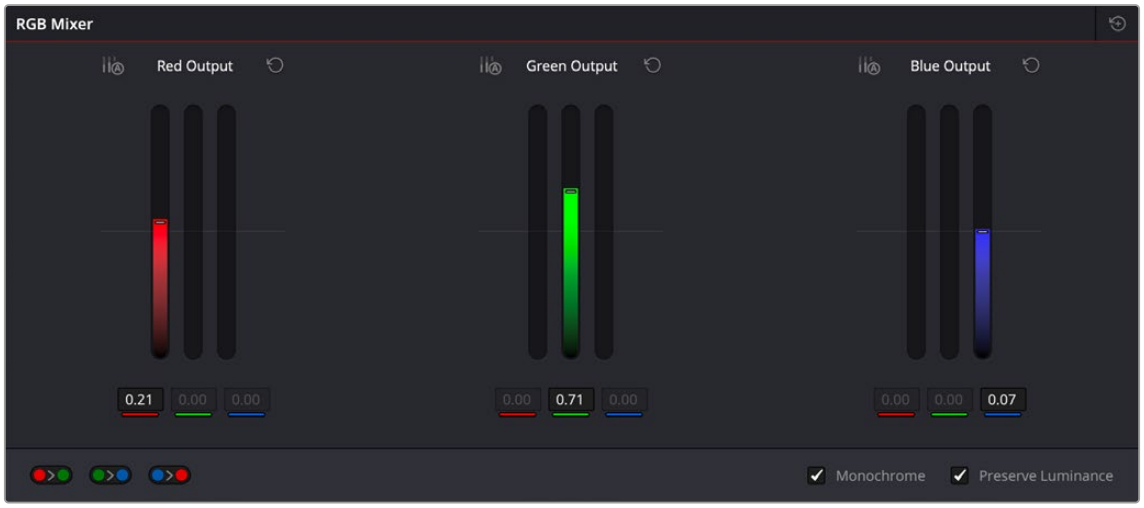
A set of three buttons at the bottom of the RGB Mixer lets you easily swap two channels with one another. This can be useful as part of a creative look, or corrective in instances where two channels are accidentally reversed.

- **Swap Red and Green:** Swaps these two color channels.
- **Swap Green and Blue:** Swaps these two color channels.
- **Swap Red and Blue:** Swaps these two color channels.

Using the RGB Mixer in Monochrome Mode

When you turn on the Monochrome checkbox, two of the sliders within each Output group are disabled. This leaves the Red > Red slider, the Green > Green slider, and the Blue > Blue slider as the only available controls.

Keeping in mind that each of the color channels that makes up an image is itself a grayscale channel, the RGB sliders in Monochrome mode let you add different proportions of the Red, Green, and Blue color channels together to create custom grayscale versions of a shot.



Sliders at their default values when Monochrome mode is enabled

To understand why this is useful, let's consider the default values of the Red, Green, and Blue sliders. To emulate the human eye's sensitivity to the wavelengths of light, the Rec. 709 video standard defines an isolated Luma (Y') component as consisting of 0.2126 of the Red channel, 0.7152 of the Green channel, and 0.0722 of the Blue channels added together. This can be seen in the default values (rounded to the nearest integer percentage) of 21, 71, and 7.

This is the standard method of deriving a black and white version of a color image, and in fact produces identical results to those obtained by setting the Saturation parameter to 0.

However, there have traditionally been other ways of mixing the colors of life into different grayscale interpretations. For example, photographers often use colored filters in conjunction with black & white film stocks, such as a yellow/green filter to emphasize pleasing skin tone for lightly complexioned people. A much older example is the use of black & white film stocks with different sensitivities (old orthochromatic stocks were not sensitive to red wavelengths, recording only blue and green to create an image).

Using the RGB Mixer with Monochrome mode turned on gives you the ability to mix your own custom blends of all three color channels to emphasize the creative characteristics you require. For instance, increasing the mix of blue and decreasing red and green can give skin tones a darker, metallic sheen. The following screenshots show multiple versions of the same image with different monochrome mixes.

Three monochrome mixes of the same image.
The top image is the result of setting saturation to 0.

Like the parameters in Color mode, you can use the RGB Mixer's Monochrome mode to subtract one color channel from the others, for even more creative effects.

Chapter 132

Curves

The Color page has a powerful curves interface that provides controls for adjusting color and contrast with the Custom Curves, as well as a variety of “Hue” or “HSL” curves that let you make more targeted adjustments to hue, saturation, and luminance in a variety of ways.

Introduction to Curves

The Curves palette, selectable via one of the toolbar buttons above the Center Palette panel of the Color page, has six modes that provide different curve-based methods of manipulating the color and contrast of an image. Each curve lets you adjust a customizable region of the image based either on image tonality (zones of lightness or darkness), hue (specific colors), or saturation (intensity of color). All curves can be adjusted using either the pointer, or knobs on the DaVinci Resolve Mini or Advanced control panel.

The Curves palette is color-space-aware when you're using Resolve Color Management (RCM) or ACES. What this means is that the overall range of each curve better fits the overall data range of the current clip no matter what Timeline Color Space you're using, for both SDR and HDR mastering. This makes curves adjustments easier, more specific, and a more consistent experience, no matter what your workflow happens to be.

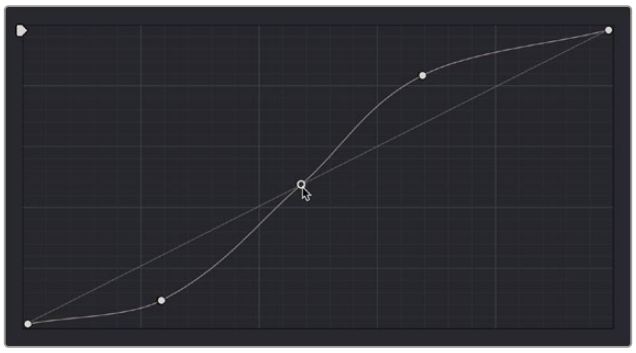
TIP: All curves in DaVinci Resolve can be used to affect the overall image, or limited to affect only a specific portion of the image as a part of a secondary operation using qualifiers, windows, imported mattes, or any combination of the three.

Adjusting Curves Using the Mouse

All Color curves in DaVinci Resolve use the following controls for basic on-screen adjustment using the pointer, controlled either with your mouse, pen, or other input device of choice.

Methods of adjusting curves using the on-screen interface:

- **To add a control point:** Click anywhere on a curve. A control point is added at the position of the mouse where you clicked, and the curve is altered, if necessary, to match the new control point's position.
- **To add a control point without altering the curve:** Hold the Shift key down, and click anywhere on or around a curve. A control point is added to the curve at the position of the pointer where you clicked, but the curve is not altered.
- **To snap a control point to the neutral diagonal of the curve:** (Custom curve only) Hold the Option key down while dragging any control point on the curve. A diagonal line appears indicating the neutral state of the image, and the control point will snap to it. When you release the Option key and then press the Option key again after releasing, the diagonal guide line disappears.

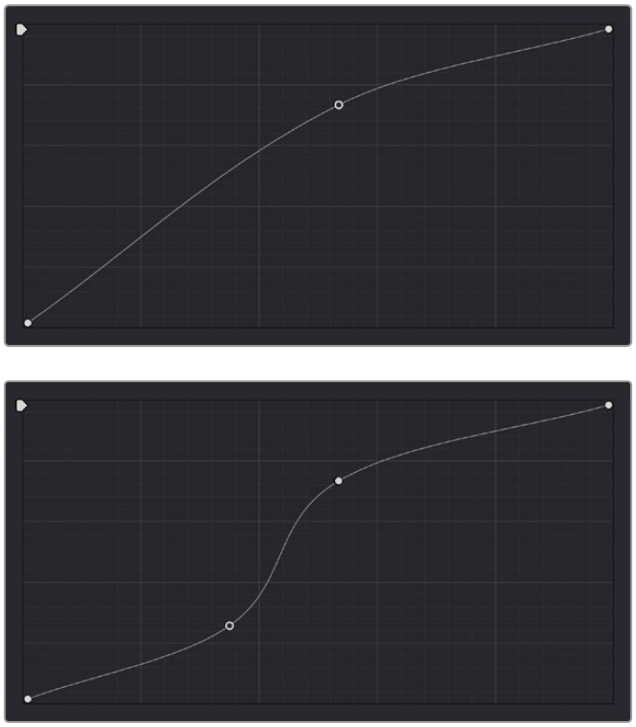


Snapping a curve's control point back to its neutral position by holding down the Option key

- **To remove a control point:** Right-click any control point to make it disappear.

- **To reset a single color channel curve to a completely neutral setting:** Click the reset button to the right of that color channel's intensity slider.
- **To reset all color channel curves:** Click the Reset Custom Curve button at the upper right-hand corner of the Curves palette.

  By default, a control point influences the portion of each curve that falls between its neighboring two control points.



Control point adjustments affect the entire portion of a curve between adjacent control points.

In the top screenshot, you can see that the control point at the position of the pointer is affecting the larger part of the curve that falls between the lower left-hand control point (which is there by default), and a user-created control point placed up within the highlights of the curve.

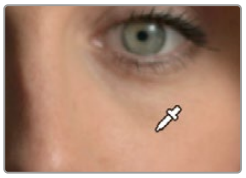
In the bottom screenshot, an additional control point to the left of the one being adjusted limits the area of the curve that is adjusted. By careful placement of additional control points, you can make extremely targeted adjustments to images using the Custom curves.

This example highlights the importance of using control points to "lock off" portions of a curve at a neutral or nearly neutral position to prevent changes to specific portions of an image, even while using other control points to make changes.

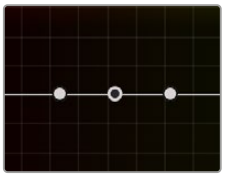
NOTE: The HSL curves also have an optional adjustment mode using Bezier curves that will be covered in those sections.

Sampling Images to Place Control Points on Curves

Another way you can add control points to curves is to move the pointer to the Viewer, and click to sample a color value and place a control point at the position on the currently open curve that corresponds to that value. This works with Custom, Hue, and HSL curves.



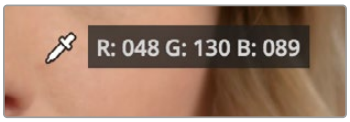
Clicking on a feature of the image



Creates a control point on the currently open curve

Showing Picker RGB Values

While you're dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the Show RGB Picker Values In submenu in the Viewer's option menu has options for displaying either 8- or 10-bit tristimulus values.



The color picker tooltip that appears when you turn on Show RGB Picker Values

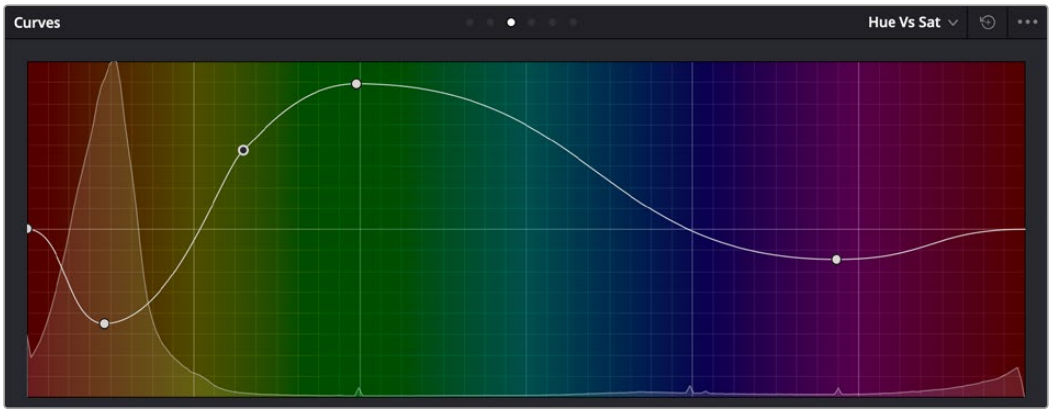
Curves Histograms

The Custom curves and HSL curves all show a histogram that represents the input of the currently selected Correction node, which you can use to guide your adjustments. The Histograms submenu of the Curves palette's Option menu lets you choose to disable these histograms, or to switch the histograms between showing the input or the output of the node. If you switch to Output, the histograms will update to show you the result of your adjustments, at the expense of seeing the image data that the curve is actually working upon.

The Custom curves show a YRGB histogram:

The histogram appearing underneath the Custom Curves shows a YRGB histogram analysis

Each Hue or HSL curve shows a histogram analysis of the two color channels that Curve acts upon: hue against saturation level, luminance against saturation level, or saturation level against saturation level, to give three different examples. In the case of Hue or HSL curves, these histograms make it easy to see which parts of the Curve controls will actually affect image data.



The histogram appearing underneath the Hue vs Sat curve plots all saturation levels at each value of hue

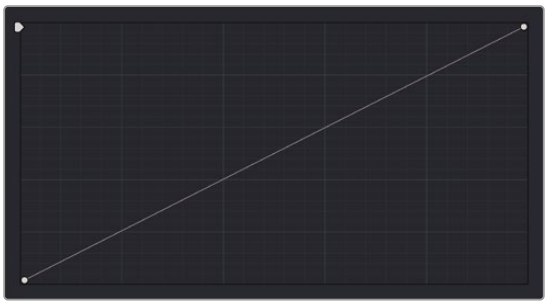
Custom Curves

DaVinci's Custom curves provide smooth adjustment of each clip's Y, R, G, and B channels. The Custom curve mode of the Curves palette is divided into two areas, the Curve Editor to the left, and the Curve controls to the right. The editor contains the actual Curve controls you use to adjust the image. The controls at the right let you choose which curves you're adjusting, and adjust their intensity.

The Custom curves seen used to create a gentle "S" curve adjustment with four additional control points added

The Custom curves are useful for making more tonally specific, channel-by-channel adjustments to an image than can be accomplished using the Color Balance controls. They're also useful for making strange and wonderful stylistic adjustments through unusual alterations to different combinations of color channels.

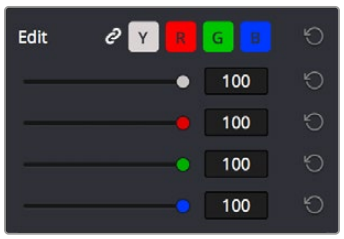
Although the ganged Custom curves appear to be a single curve control, the Custom curve editor is actually presented as a series of overlaid curves, and the YRGB curves all appear within a single editor. The default, neutral position of the Custom curves is a diagonal line that runs from the lower-left black point of the image through the upper-right white point.



The neutral diagonal position of the curve at which no adjustment is made

The horizontal axis represents the range of image tonality in the original image, from black (at the left) to white (at the right), while the vertical axis represents the range of alteration you can make. By adding control points to the surface of the curve and raising or lowering it at different regions, you are actually remapping the original horizontal “input” value of a color channel to an “output” value of your choosing.

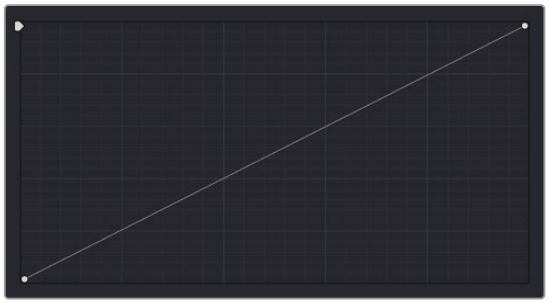
Additional controls appear to the right of the curve editor itself. A top row of buttons let you select the curve corresponding to an individual color channel for isolated adjustment, while a vertical stack of four sliders let you adjust the intensity of each color channel’s curve.



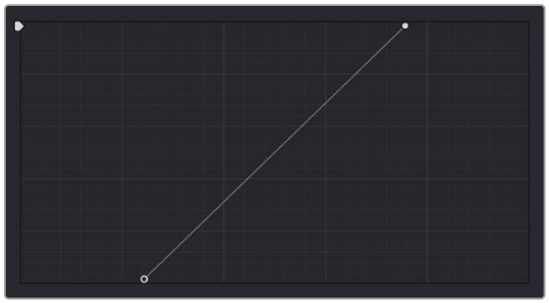
The channel-editing buttons and curve intensity sliders appear to the right of the curve editor

Editing the Top and Bottom Control Points of Curves

You can also edit curves using the default two control points that the curve control starts out with in the Curve Editor. The Black Point control (at the lower-left) and the White Point control (at the upper-right) let you expand and compress the video signal similarly to using the Lift and Gain Master Wheel controls in the Color Wheels palette.



The Curve control at its original state



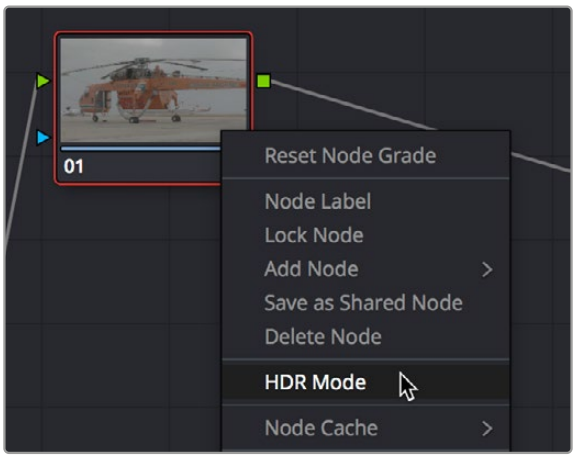
The Black and White Point controls dragged to the right and left to expand the signal

You can use the Black and White Point controls in the following ways:

- **Using the Black Point control:** Dragging this control up makes a lift adjustment to raise the black point of the signal. Dragging this control to the right makes a lift adjustment to lower the black point of the signal.
- **Using the White Point control:** Dragging this control down makes a gain adjustment to lower the white point of the signal. Dragging this control to the left makes a gain adjustment to raise the white point of the signal.

HDR Grading Using Curves

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you're working on by right-clicking that node in the Node Editor and choosing HDR mode from the contextual menu (only available in Resolve Studio).

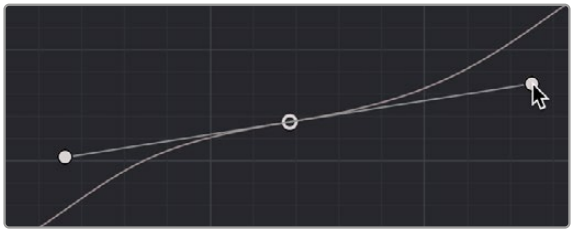


Using a node's contextual menu to put that node into HDR mode

This setting adapts that node's controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.

Enabling Editable Splines in the Custom Curves

When the Curve palette is in Custom mode, you can choose Editable Splines from the option menu to expose Bezier spline handles on any selected control point, which let you make more precise curve adjustments whenever necessary.

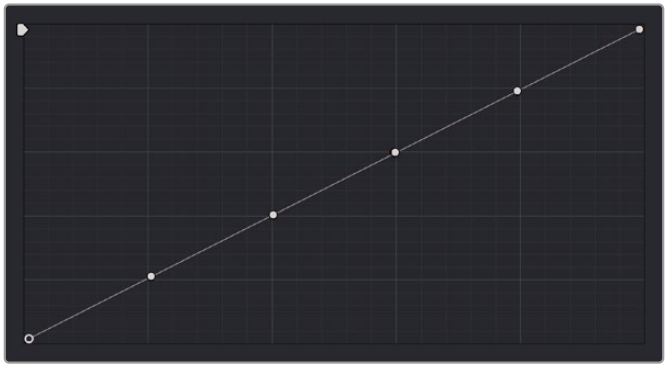


Custom curve with editable splines enabled

NOTE: Beware of making curve adjustments that are too sharp, or with control points that are too close together, as they can introduce unwanted contouring within the image, causing flattening or solarization in parts of the image that you may not want.

Adding Default Anchors to the Custom Curves

You can also choose Default Anchors from the option menu of the Curve palette in Custom mode to place three additional control points on the curve, dividing the curve into five segments that affect the shadows, low midtones, medium midtones, high midtones, and highlights of the image.



Custom curve with Default Anchors exposed

Ganging and Unganging Custom Curves

By default, the Custom curves are ganged, so that curve adjustments affect a clip's YRGB channels all together, resulting in an adjustment to image contrast that's similar to using the Master Wheels in the Color Wheels palette. When making this type of adjustment, increasing contrast also increases image saturation, while reducing contrast also reduces image saturation. Since curves can be manipulated with greater specificity than the three Master Wheels, you can make much finer contrast adjustments using the YRGB curves than when using the Master Wheels only.

Turning ganging off lets you use the full power of Custom curves to alter the image. Unlike the Color Balance controls, each of which adjust all three color channels simultaneously, the Curve controls let you adjust each channel individually when Gang Custom Curves is turned off.

To disable Custom curve ganging:

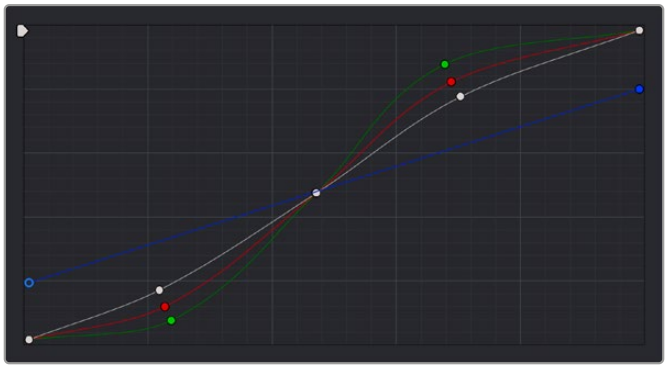
- Click the Curve Edit button that corresponds to the curve channel you want to edit. Clicking any Curve Edit button highlights that curve to make it easy for editing when curves overlap one another. Once one or more curves is offset from the others, you can freely edit any curve by dragging its control points.

Custom Curve Edit buttons are to the left, the Gang button is to the right

To re-enable Custom curve ganging:

- Click the Gang button to the left of the Curve Edit buttons.

Editing color channels via individual curve adjustments lets you make smooth color-channel specific corrections, or you can make radically individual adjustments to create a wide number of creative effects.



Turning off curve ganging lets you independently adjust each curve

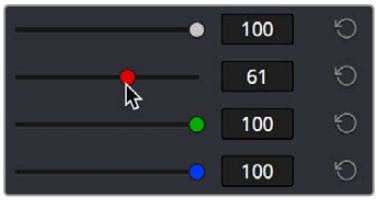
TIP: When curve ganging is disabled, the Luma curve allows you to adjust the Y channel by itself, which is similar to using the Y-only Lift/Gamma/Gain knobs of the DaVinci Resolve Micro, Mini, or Advanced Control Panels. When making this type of adjustment, increasing luma contrast results in a perceptual decrease of image saturation.

Copying Custom Curves From One Color Channel to Another

Even if you've unganged the Custom curves, you can still mirror one curve's adjustments to another by copying it using the "Copy to Red/Green/Blue" commands in the Curve palette's option menu.

Curve Intensity Sliders

Four Curve Intensity sliders to the right of the Curve Editor, one for each channel, let you mix between the current curve's effect on the clip, and the original state of the image before you altered the curve. The default Intensity of 100 results in that curve exerting its full effect on the image, while an intensity of 0 results in that curve having no effect on the image. The Intensity sliders provide an easy way to "split the difference" between a curve adjustment and the previous state of the image.



Lowering the Curve Mix slider reduces the effect of that curve's adjustment on the image.

YSFX Sliders

Each of the Custom curves (Y', R, G, and B) has a vertical YSFX slider at the upper left-hand corner of the Curve Editor that lets you invert any or all color channels by any amount you want, to create different types of stylized effects.

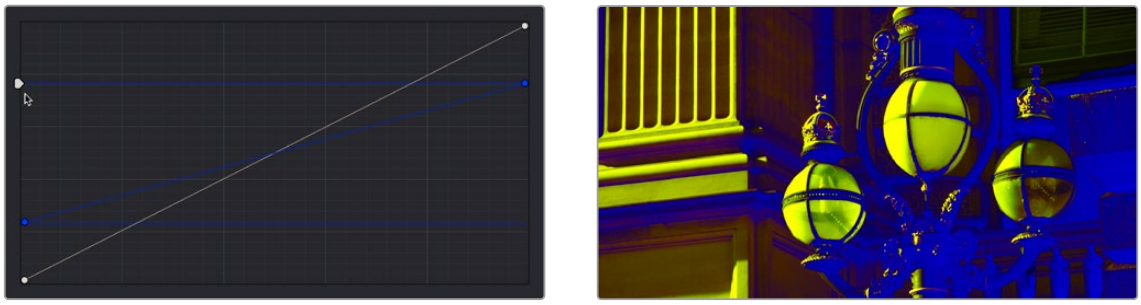


Image with the Luma channel modified using the vertical YSFX slider

As with all other adjustments in the Color page, YSFX may be combined with Power Windows or HSL qualification to limit channel inversions to specific portions of the image for creative purposes.

Soft Clip

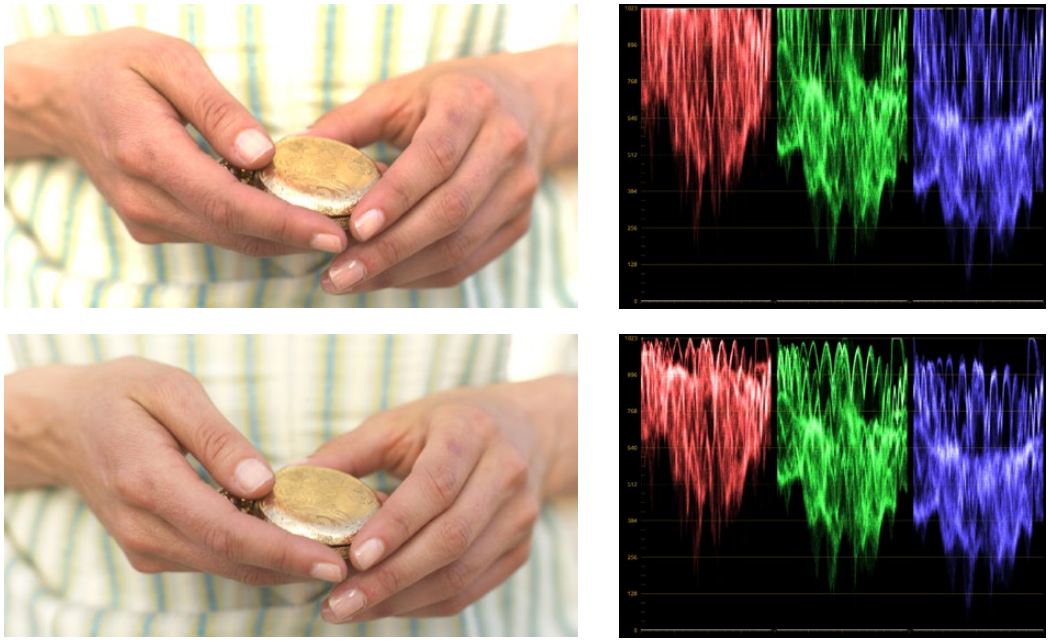
The Soft Clip controls consist of four sliders underneath the Curve controls of the Custom curves, and give you an interface for adjusting highlight and shadow soft clipping either overall, with Ganging enabled, or on a per-channel basis. The Soft Clip controls are intended to provide clip-by-clip adjustment, as opposed to the Generate Soft Clip LUT settings, which let you set one soft-clipping setting for the entire program.

> For more information on the Soft Clip LUT setting, *see Chapter 4, "System and User Preferences."*

High and Low Soft Clip controls within the Curves palette

Soft clipping lets you apply a "knee" to any clipping that occurs at the upper or lower extremes of the image, and can be used to quickly ease off any unpleasantly harsh loss of detail that occurs as a result of blowing out the highlights or crushing the shadows too aggressively.

In the following example, the screenshot at top has had the highlights deliberately blown out by excessively boosting the highlight contrast. As you can see, the edges of the clipped area lack detail. The screenshot at bottom shows the same image with soft clipping increased for all three color channels. The result retrieves detail, compressing the highlights to bring the tops of each color channel back within the allowable range.



Using High Soft Clip to pull highlight details into the viewable range

Ganging and Unganging Soft Clip Controls

Soft clipping can be simultaneously applied to all three color channels by enabling the Ganging control (on by default), or you can disable Soft Clip ganging to individually adjust each channel. For example, using soft clipping on individual channels can be useful for legalizing RGB out-of-gamut errors for channels that over- or undershoot your QC standards.

To disable Soft Clip ganging and edit soft clipping for individual color channels:

- Click the channel control button corresponding to the color channel you want to edit, and then drag the sliders to create the desired adjustment.

To re-enable Soft Clip ganging:

- Click the Ganging control to the left of the Soft Clip channel controls.

> **TIP:** Applying too much soft clipping to individual color channels may add an unwanted color tint to the corresponding highlights or shadows of an image. To avoid this, use the soft clipping parameters with ganging enabled to clip all three color channels equally.

Soft Clip Controls

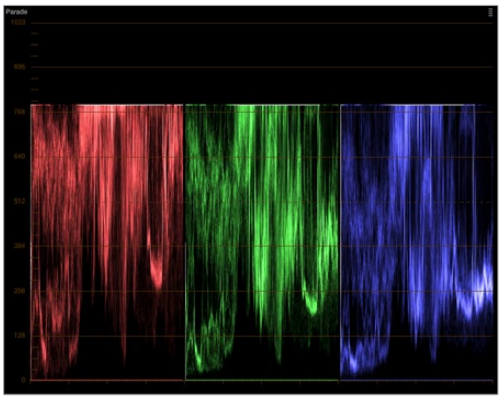
Whether all channels are ganged or not, soft clipping is controlled via two sliders and two additional parameters for each color channel.

High

The High Clipping Point slider lets you adjust the maximum signal level above which the signal is clipped. Any pixels above the clipping level are made equal to the clipping level.

The High Clipping Point defaults to a digital level of 1023 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the left causes the highlights of the image to clip at a lower level, resulting in lower, dimmer maximum levels.

Selecting and adjusting the high clip



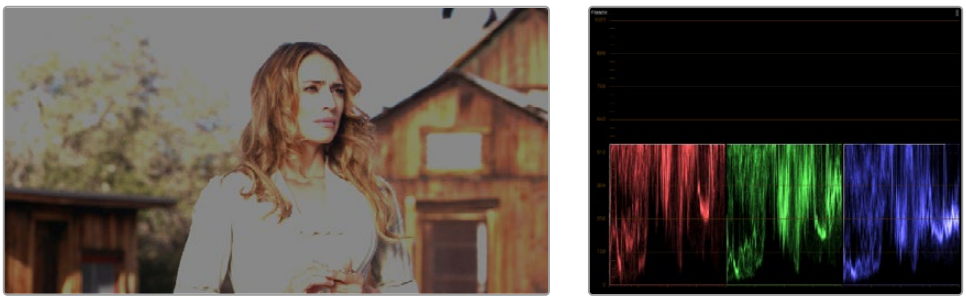
RGB Parade displays the clipped image

At the default position, no clipping occurs and image data that you push above 1023 on the internal scopes is preserved and passed through the image processing pipeline to subsequent nodes. For example, in the following two screenshots, the highlights in the screenshot at top are blown out raising the gain dramatically in Node 1. In the screenshot at bottom, a subsequent adjustment in Node 2 lowers the gain and retrieves all the previously clipped values.

The image is clipped using the Gain control in Node 2

The image data that was clipped in Node 1 is retrieved in Node 3 by lowering the Gain control. This illustrates the preservation of deliberately clipped data.

However, if at any point in a node tree you drag the High Clip slider to the left, even by a single digit, all image data above the new clipping threshold is discarded from that node forward. In the following example, the High Clip slider in Node 1 is lowered. The result is that all clipped image data is discarded. As a result, when Node 2 lowers the gain, there is no image detail left to retrieve, and all three channels exhibit flattening.



Lowering the High Clip slider in Node 1 forces all image data above the new High Clip threshold to be irretrievably discarded. Clipped data cannot be brought back by subsequent nodes.

High Soft

The High Soft slider sets the threshold, below the clipping point, at which highlights begin to compress before hard clipping. At unity, no soft clipping occurs. As you raise this value, more and more of the clipped highlight values are compressed, rather than clipped, resulting in softer, more pleasant "glowing" highlights.

IMPORTANT: Image data that was clipped "in camera" is not necessarily retrievable using the Soft Clip controls, although there may be some preserved overhead in the super-white highlights of Y'CbCr-encoded video data.

Low

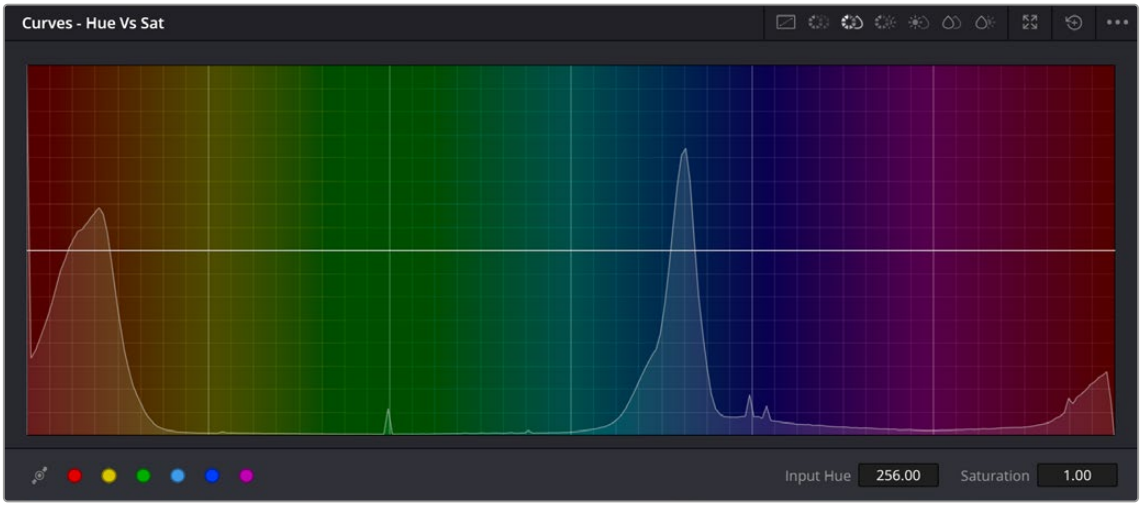
The Low Soft Clipping Point slider lets you adjust the minimum signal level at which the signal clips. This defaults to a digital level of 0 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the right causes the shadows of the image to clip at a higher level, resulting in lighter minimum levels, and a lower-contrast image with lighter (possibly milky) shadows.

Low Soft

The Low Soft slider sets the threshold, above the minimum clipping point, at which shadows begin to compress before hard clipping. At unity, no soft clipping occurs. As you drag this slider to the right, more and more of the clipped shadow values are compressed, rather than clipped, resulting in a softer, more pleasant rolloff in the shadows.

The HSL Curves

Three sets of Hue curves, and additional Lum vs. Sat, Sat vs. Sat, and Sat vs Lum curves, let you make different types of curve-based alterations to the image. Whereas the Custom curves let you make adjustments to the color channels of an image based on tonality (for example, boosting the Red channel in the highlights while lowering it in the shadows), the Hue curves let you make adjustments to the hue, saturation, or luma of elements in an image based on their hue.

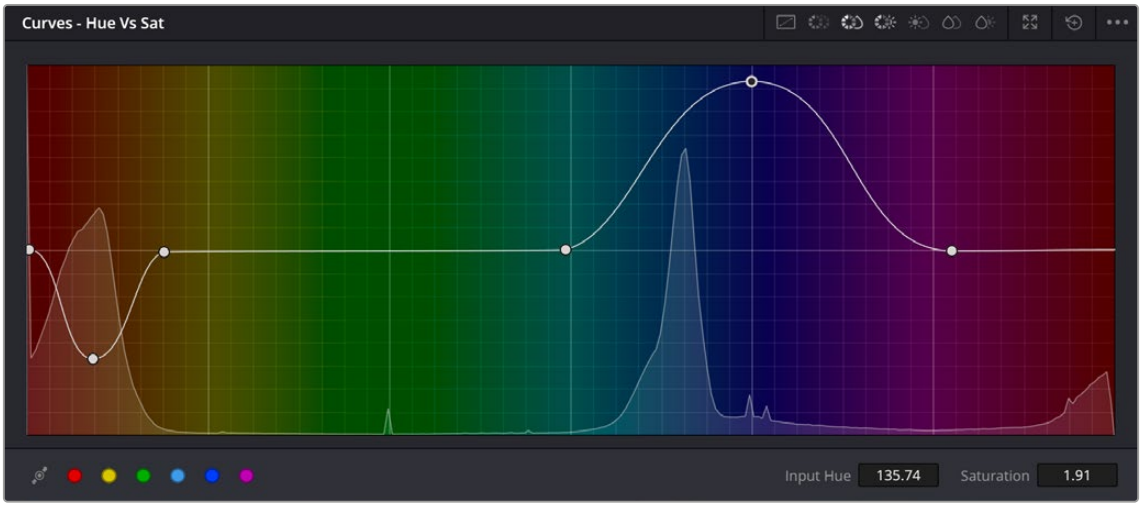


Curves controls including six-vector selection and bezier handle button

For example, you could use the Hue vs. Sat curve to selectively lower the saturation of everything that's blue, while raising the saturation of everything that's red.

You can use these curves to make adjustments similar to those made using HSL qualification, but with one critical difference. Curve adjustments are mathematically smoother than the matte-limited adjustments of HSL qualifiers, so it can sometimes be easier to make specific alterations that blend smoothly with the rest of the image, without the potential for artifacts at the edges of qualified keys that can sometimes defeat a seamless result.

On the other hand, it is often easier to define more distinct boundaries between separate elements using HSL qualification. Only time and experience will help you determine which tools are best for which situations.



Right–Original image, Left–the image as altered by the Hue vs. Sat curve shown above

Unlike the Custom curves, which default to a diagonal position where lower left represents the black point and upper right represents the white point, Hue and Sat curves are flat. In the case of the Hue vs. Hue/Sat/Lum curves, the horizontal range of the curve from left to right represents the overall range of possible hues, from red through green through blue and then cycling back to red.

Because the range of hues cycle smoothly from the left to the right edge, changes that affect the curve near the left boundary of these curves loop smoothly around to the right boundary, and vice versa, such that the left and right sides of the curve always move together (as you can see in the above screenshot).

IMPORTANT: When using Hue curves, the range of hue that you isolate with control points is always relative to the RGB input connected to that node. That means if you change the hue of a shirt from blue to red using Hue vs. Hue and you then want to raise the same shirt's saturation with the Hue vs. Sat curve within the same node, you need to add control points to the same range of blue for both curves.

Image Sampling for Hue and Sat Curves

There's an additional way to use Hue curves in DaVinci Resolve. Whenever one of the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, Lum vs. Sat, or Sat vs. Sat curve tabs are open, clicking or clicking and dragging over any range of pixels within the Viewer area samples the hues and/or image tonality of that region of the picture, and automatically places three control points on the currently open curve that correspond to the range of color and contrast you sampled.

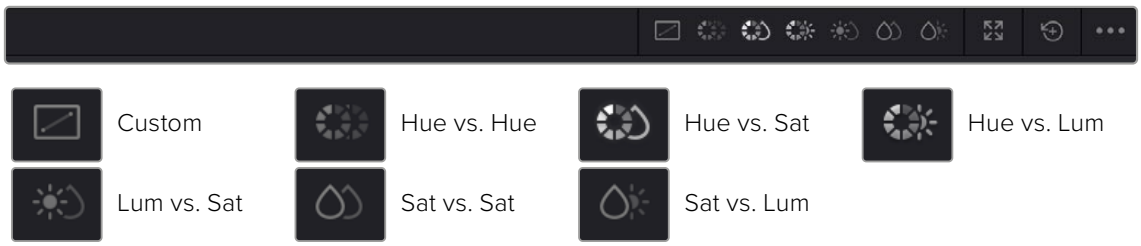
Additional Controls in the Hue and Sat Curves

While the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, Lum vs. Sat, and Sat vs. Sat curves can be adjusted similarly to the Custom curves, they have additional controls running underneath the curve graph.

- **Enable Bezier button:** Turning this button on forces a curve to use Bezier control handles, rather than the default DaVinci Resolve Curve Control points, to manipulate each control point on the curve. With Bezier handles enabled, click any control point to reveal its two Bezier handles. Drag either handle to alter the shape of the curve at that control point.
- **Six-Vector Color Patches:** The Hue curves each have six buttons for automatically adding control points to manipulate the red/yellow/green/cyan/blue/magenta ranges of hue. Clicking any of these buttons adds three control points; two to define the outer range of hue to be adjusted, and a middle control point that you use to make the adjustment.

- **Input and Output (Hue Rotate/Saturation/Lum) fields:** These two number fields correspond to the horizontal and vertical adjustment values for the currently selected control point. Click any control point on a curve to view or alter these values. The label of the second field depends on the curve that's selected.

The following sections describe each available curve in more detail. Each type of curve is accessed by selecting the appropriate icon in the upper right of the Curve Palette.



Hue vs. Hue

The Hue vs. Hue curve lets you change any hue to any other hue. In the following example, the image on the left is the unadjusted original. The image on the right has had the orange jacket shifted to an olive green via a set of three control points.

Changing the hue of the woman's jacket using the Hue vs. Hue curve; Left–original image, Right–altered image

One excellent use of the Hue vs. Hue curve is to quickly and subtly alter elements that require only minor adjustments. For example, a sky that appears a bit too cyan can be made into a richer shade of blue with a small adjustment.

Hue vs. Hue is also useful for making more radical changes to elements that might be too noisy to key successfully using the HSL qualifier controls. For example, red autumnal foliage blowing in the wind might result in a chattery matte, but you can use the Hue vs. Hue curve to change reds to greens, without having to worry about aliased matte edges giving your correction away.

Hue vs. Sat

The Hue vs. Sat curve lets you selectively alter the saturation of any hue within the image. This is a terrific tool for creative effect, allowing you to quickly and easily boost the saturation of elements you want to catch the viewer's eye, while reducing the saturation of elements you'd prefer the audience not dwell upon.

This can be extremely useful for legalizing over-saturated overshoots or undershoots during a QC pass. For example, desaturating reds that are off the charts while leaving everything else alone.

Lowering the saturation of the woman's jacket using the Hue vs. Sat curve; Left–original image, Right–altered image

The Hue vs. Sat curve can also be a powerful tool for increasing the color contrast of images that seem lackluster and flat. By boosting the saturation of colorful elements that are distinct from the dominant palette of a scene, you can add variety to an otherwise monochromatic image.

Hue vs. Lum

The Hue vs. Lum curve lets you increase or decrease the lightness of elements of specific colors.

Darkening the woman's jacket using the Hue vs. Lum curve; Left–original image, Right–altered image

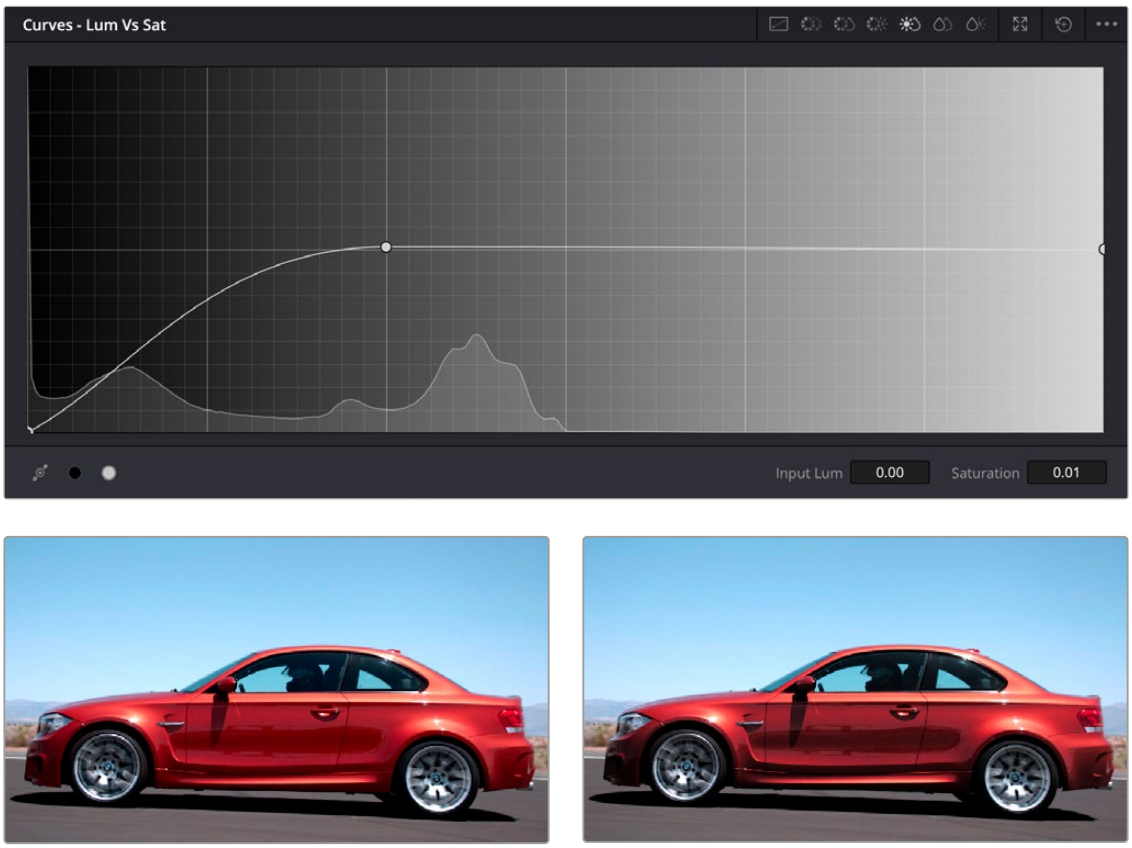
This is a tricky curve to use with highly compressed footage, as it can quickly reveal artifacts in the image if you aren't careful. However, if you're working with very high-quality footage, this can be a great tool to darken specific hues to add richness and depth, or to lighten colorful elements to which you want to draw attention.

Lum vs. Sat

The Lum vs. Sat curve is similar to the Custom curves in that alterations to the saturation of an image are based on user-definable ranges of image tonality, rather than hue. In the following example, the Lum vs. Sat curve is being used to decrease selectively the saturation of everything falling into the highlights and shadows of the image, while increasing the saturation of everything within the midtones.

In the following example, a vividly saturated treatment results in shadows that seem artificially colorful. Using the Lum vs. Sat curve, it's easy to gradually desaturate everything below a certain range, with a nice smooth falloff.

This is an outstanding curve to use for creative effect, for example, slightly boosting saturation within the midtones while reducing saturation in the shadows to increase the depth of the darkest portions of the image. It's also a great curve to use to solve QC violations. For example, if you have illegal saturation in the highlights of an image, you can use the Lum vs. Sat curve cleanly and smoothly to lower the specific values that are causing problems.



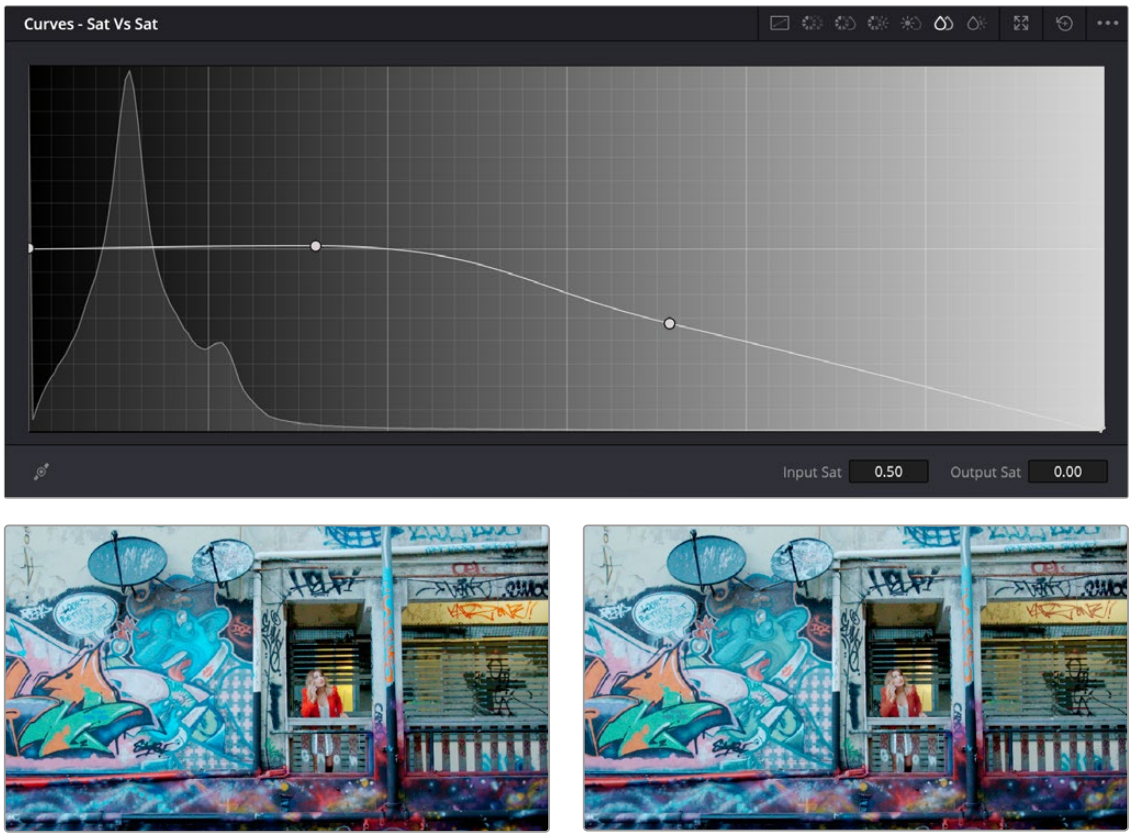
Selective desaturation in the shadows and highlights using the Lum vs. Sat curve; Right–original image, Left–altered image

Sat vs. Sat

The Saturation vs. Saturation curve lets you selectively manipulate image saturation within specific regions defined by the image's original image saturation. Control points added to the left of this curve affect areas of progressively lower saturation, effectively letting you increase or decrease the saturation of lower-saturated features. Control points added to the right affect areas of progressively higher saturation, letting you increase or decrease the most saturated features of an image.

Like all curves, this operation is extremely useful for stylizing the image. You can create custom vibrance operations, where you selectively increase the saturation of low-saturated regions of the image in different ways to give the picture more “pop.” It’s also an excellent tool for taking care of over-saturated areas of the picture when adhering to conservative QC requirements. You can specifically desaturate only the most over-saturated parts of the picture, without affecting similar hues at lower levels of saturation.

In the following example, you can see that the portion of the image with the highest saturation has been desaturated, while the rest of the image has been left alone.

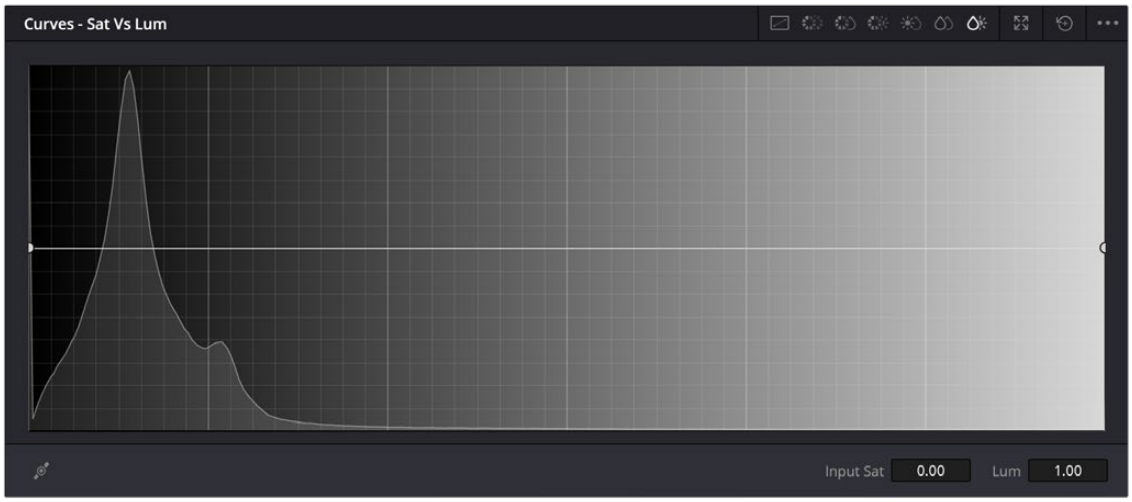


Desaturating only the highest saturated elements in the picture by lower control points at the right of the Sat vs. Sat curve

Sat vs. Lum Curve

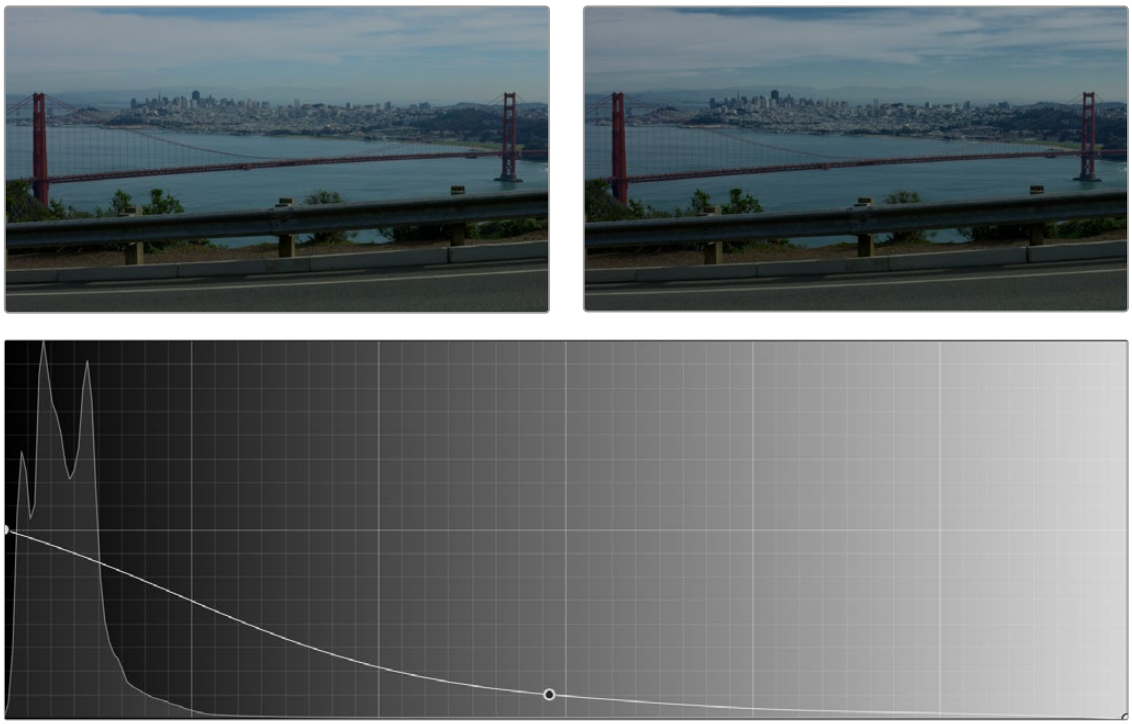
The inverse of the Lum vs. Sat curve, Sat vs. Lum lets you quickly adjust the luminance of pixels that falls within a particular range of saturation. This is useful for cases where regions of the image you want to make lighter or darker happen to coincide with an identifiably consistent range of saturation.

To help guide your adjustment, the histogram drawn for this curve lets you see how many pixels there are at each level of saturation found within the image, with the leftmost part of the curve representing minimum saturation, and the rightmost part of the curve representing maximum saturation. Seeing where the levels of saturation lie in the current image help you to quickly make targeted luminance adjustments when you sample the region of the image you want to adjust to add points to this curve.



The Sat vs. Lum curve

In the following example, the right side of this curve is lowered so that the most saturated parts of the image become darkened. You might want to make an adjustment like this to emulate one of the properties of film, where highly saturated colors block more light from passing through the emulsion than less saturated colors. Or, you may do this in an effort to desaturate bright colors in highlights that might otherwise clip past maximum white. Or, you might do this to quickly darken highly saturated skies.



(Top Left) The original image, (Top Right) The highly saturated blue sky and sea reflections are darkened to a more intense blue by lowering the right part of the Sat vs. Lum curve (Bottom).

Chapter 133

ColorSlice

This chapter focuses on using the ColorSlice tool, allowing you to make targeted changes to specific color ranges that seamlessly integrate with the rest of the image.

Contents

ColorSlice 2989
Vectorspace ColorSlice Controls 2989
Global ColorSlice Controls 2990
Using Color Slice 2991

ColorSlice

ColorSlice is a fixed vector grading tool that allows you to qualify a range or ranges of colors that all blend smoothly together, making a more seamless image than using the HSL qualifier.

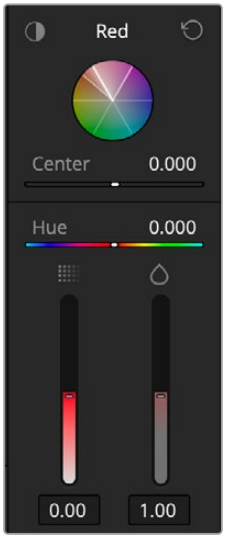
The ColorSlice vector-based grading tool

You can use ColorSlice to set overall density, saturation, and hue parameters to replicate different CMY print processes and to change brightness and saturation for each vectorspace slice. To achieve deep filmic colors and looks, brightness is controlled in a subtractive way when adjusting saturation, so saturated colors are not unnaturally bright and do not need luminance adjustments.

Increasing the Saturation (left) creates a brighter red, while using the ColorSlice tool (right) creates a deeper red.

Vectorspace ColorSlice Controls

The ColorSlice tool is comprised of seven different vectorspace slices. Each vectorspace slice controls a range of colors based on the conventional vectors on the Vectorscope: Red, Green, Blue, Cyan, Magenta, and Yellow. In addition, a seventh vector has been added for skin tones.



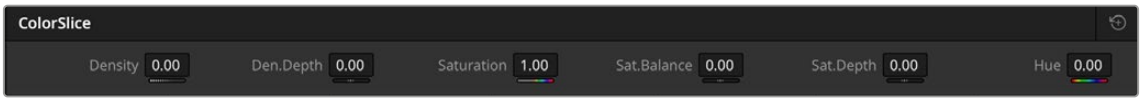
The Red ColorSlice vectorspace slice controls

Each vectorspace slice is composed of the following controls:

- **Highlight:** Click and holding on this icon will enable a highlight view as long as you hold the button down, showing the areas of the image that will be modified by the control. You can also switch between each vectorspace's highlight permanently by activating a highlight view in the Viewer first to make it easier to refine the parameters below.
- **Slice Color:** A name that represents the color of the area controlled (Red, Green, Blue, etc.).
- **Reset:** Resets the all the vectorspace slice controls back to the default levels.
- **Color Wheel:** A visual representation of the vectorspace slice. All colors within the brightened wedge are what will be adjusted by the controls.
- **Center:** This is the only adjustable qualifying control. Sliding this bright line back and forth will move the center of the color range, letting you slightly change which colors are weighted more in the qualifier. You cannot move the center out of its range. Use this tool in conjunction with the highlight view to make sure that the specific colors you want to adjust are qualified.
- **Hue:** Changes the hue of all the colors within the vectorspace slice. Adjusting this control does not affect the qualification of the original color.
- **Density:** Adjusts the density of the colors inside the vectorspace slice by adjusting the luminance of more saturated colors to emulate a subtractive color film process.
- **Saturation:** Adjusts the saturation of colors qualified by this slice using a subtractive color model that prevents highly saturated colors from becoming unnaturally bright.

Global ColorSlice Controls

In addition to the individual vectorspace slice controls, there are a set of global controls along the top of the tool. These will change the values of the entire image.



The ColorSlice Global controls

- **Density:** Adjusts the luminance of more saturated colors to emulate a subtractive color film process.

- **Den.Depth:** Controls the effect of density adjustments on brighter areas of the image.
- **Saturation:** Adjusts saturation using a subtractive color model that prevents highly saturated colors from becoming unnaturally bright.
- **Sat.Balance:** Adjusts how saturation changes effect the luminance balance in colors with medium saturation levels.
- **Sat.Depth:** Controls the effect of saturation adjustments on brighter areas of the image.
- **Hue:** Changes the hue of all the colors within the image.
- **Reset:** Resets all ColorSlice adjustments.

Using the Numeric Parameters

In addition to the Global controls above, Each vectorspace slice has a set of four number fields that display the values of the Center, Hue, Density, and Saturation controls. These fields can be edited like any other parameter on the Color page.

To edit values directly:

- You can double-click on a field to edit its value numerically.
- You can insert the text cursor next to a value in this field and use the Up and Down Arrow keys to adjust the value one digit at a time.
- You can cut, copy, and paste values among fields.
- You can click on the field and drag left or right to adjust its value with a virtual slider.

Using Color Slice

Each vectorspace slice has a center line, which is the color where most of the weight of the adjustments will be made. By sliding the Center control back and forth, you can select which color to qualify the most of. The Center control is the only control used to qualify colors; all the other tools make adjustments to that qualification.

The Cyan color slice center is marked by a bright white line, while its color range is bounded by white lines on either side clockwise and counterclockwise.

As you adjust the Center control, you will want to take a look at the qualified colors, either by click and holding on the highlight icon in the upper left of the vectorspace slice, or by turning on the highlight in the Viewer.

Once you have the range of colors selected, you simply adjust the Hue, Density, and Saturation controls for the vectorspace slice until you get the results you're looking for. Note that pulling a perfectly clean matte is not necessary; you just want to make sure that the range of colors you want to enhance is mostly selected.

For this example, we will quickly qualify and adjust both the sky and ocean, as well as the cycler's skin tone all in the same node, at the same time using just the ColorSlice tool.

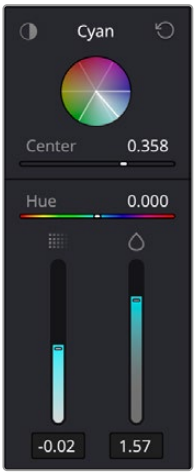
This is the initial balanced image, and we want to make the sky and ocean more vibrant, as well as accentuate the sunset light falling on the cyclist.

The original balanced shot we want to enhance

First, we open the ColorSlice tool and set our Viewer to B/W Highlight.

Using the Cyan vectorspace slice, we first adjust the Center control until we have the maximum amount of sky and ocean qualified (white). Next we will turn off our highlight and adjust the density and saturation sliders to get a nice vibrant sky and ocean.

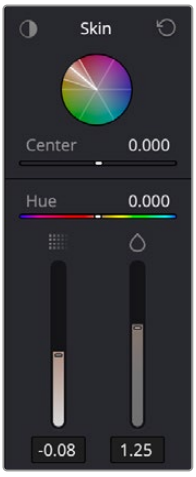
Adjusting the Cyan center control to maximize the amount of sky and ocean qualified (white)



The center, density, and saturation adjustments for Cyan (sky and ocean)

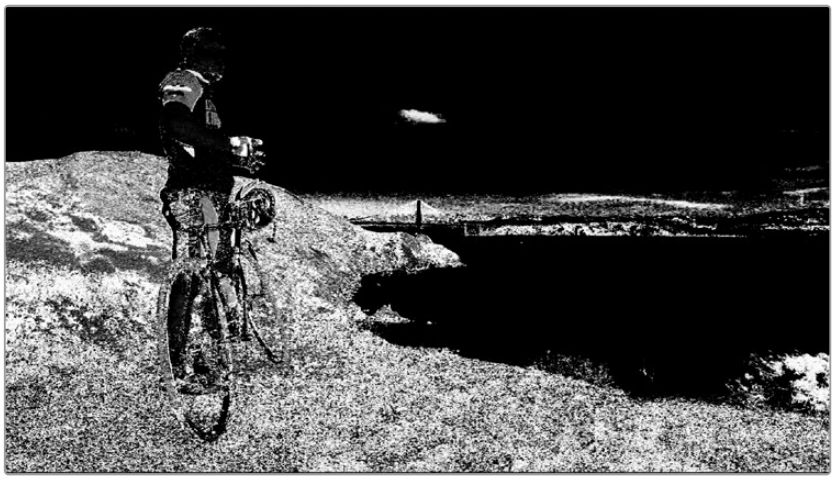
Next we will use the Skin vectorspace slice, and again turn on the highlight and adjust the center until we have the maximum amount of the cyclist qualified. However, note we also end up qualifying quite a bit of the hills behind him, which we don't want. We then turn off the highlight and adjust the density and saturation sliders until we have a rich warm glow falling on him (and the hills).

Adjusting the Skin center control to maximize the amount of the cyclist qualified (white). Note quite a bit of the hills behind him are qualified too.

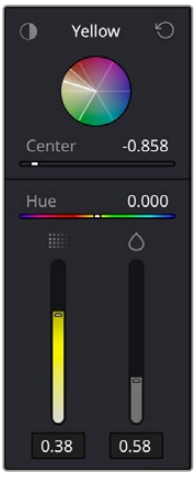


The center, density, and saturation adjustments for Skin, accentuating the late afternoon sun on the cyclist

Now we will go over to the next vectorspace slice, Yellow. Turning on the highlight, we will now adjust the center control to maximize the amount of the hills behind him that are qualified. Note that his skin tones are not qualified using this vectorspace slice, only the hills. Now we will turn off the highlight and dial back the density and saturation of the hills again that we had qualified in the previous slice.



Adjusting the Yellow center control to pick out just the hills (white). Note his skin tones are not qualified.



The center, density, and saturation adjustments for Yellow, desaturating just the hills back to normal that were inadvertently picked up in the Skin vectorspace slice previously.

The final image and result from those three fast ColorSlice operations.

The final ColorSlice image; three different operations in one node with one tool

You may have noticed that the qualification mattes pulled by these operations were full of small holes and expect to have to do a lot of tedious matte finesse operations to smooth them out. With ColorSlice, all the qualifiers blend seamlessly into the others, so there is no matte flickering or distracting speckles popping in and out as the video plays back. Of course, for tricker shots you can still limit the ColorSlice effect using Power Windows, and even other qualifiers, to direct the effect to just the areas of the frame you want it to apply to.

Chapter 134

Color Warper

The Color Warper is a powerful tool for making both highly specific adjustments to particular things in the frame, and widely general adjustments to create unique looks.

The two modes of the Color Warper each make it easy to simultaneously modify two different color attributes, either saturation and hue, or lightness and hue. This gives the Color Warper an advantage over curves, which only let you adjust one color characteristic at a time. In this chapter, you'll learn how to use both modes of the Color Warper to perform a wide variety of tasks.

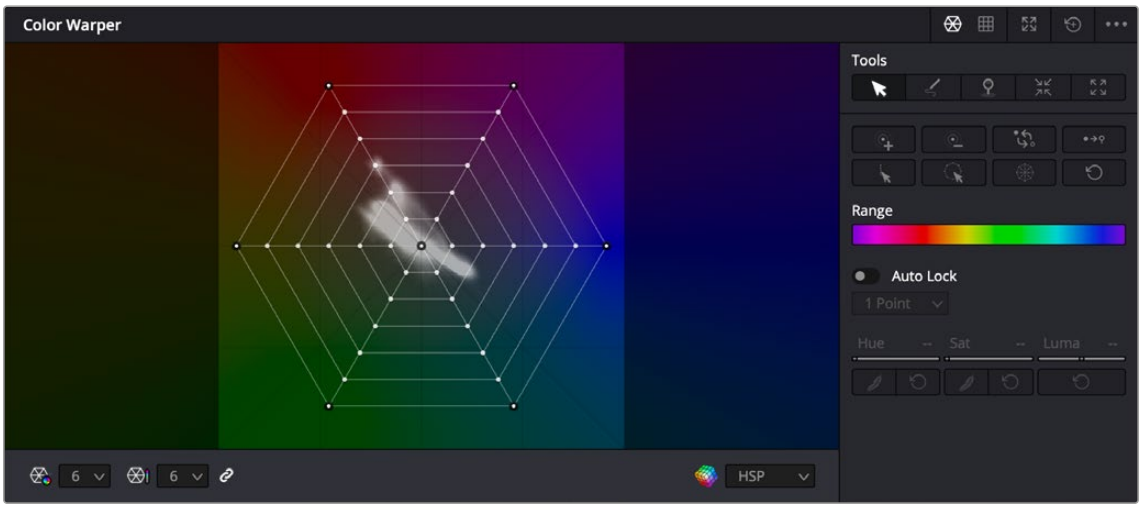
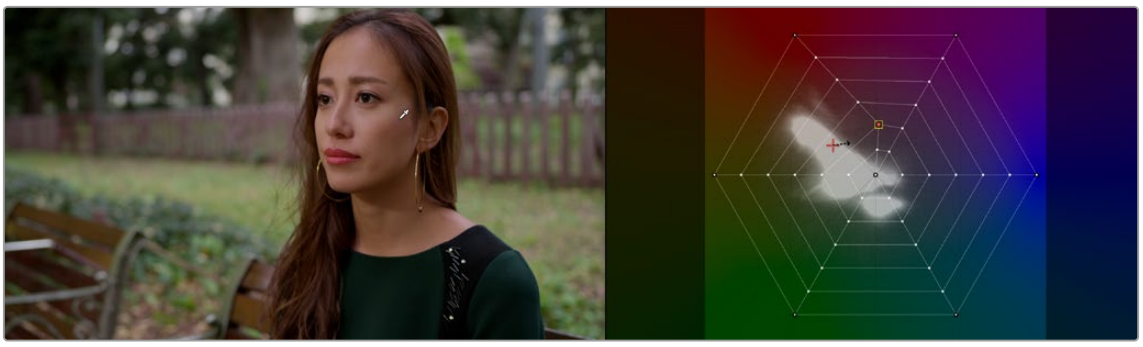
Introduction to the Color Warper

The Color Warper palette is a mesh-based warping tool that, instead of warping the spatial location of pixels, warps one set of colors into another. Better yet, unlike the HSL curves, the Color Warper lets you simultaneously adjust two color parameters at the same time, within user-selectable regions of specific hues. These adjustments, made using a grid of draggable control points, automatically have a smooth falloff from the colors you're warping to other colors that are locked into place. The smoothness of this falloff depends on the distance between the warp points that are being adjusted and other warp points that are locked in place to prevent change.



The Color Warper, located in the center palette area

There are two ways you can use this tool. You can drag the control points in the grid to make highly specific image adjustments. More intuitively, you can click to sample the image, which selects the closest grid point that affects that color, and then drag to make an adjustment with that control point.



Clicking and dragging to sample skin tone in the Viewer to adjust that color's control point on the Hue-Saturation warping grid

You can use this tool to make extremely specific adjustments to colors in an image, similar to what you might do with a Qualifier key or with the HSL curves. However, by warping the points using a grid, you can manipulate two color characteristics at the same time, adjusting both hue and saturation, or chroma and luma. In the following example, specific adjustments are being made to refine the woman's shirt, to adjust her skin tone, and to manipulate the greens of the foliage in the shot. All three of these naturalistic adjustments are smooth and artifact-free by virtue of the Color Warper's method of cleanly remapping color.

(Top) The original image, (Bottom) Manipulating the hue and saturation of the grass using the Chroma-Luma controls

You can also use this tool to create wide-ranging stylistic looks for the overall image, bending the color in creative ways that other controls don't. In the following image, the less saturated and neutral colors of the image are all warped towards a bluish-cyan, while the more saturated oranges are warped towards a saturated orange-red, to quickly create a stylistic treatment of the image.

(Top) The original image, (Bottom) Stylizing the overall image using the Hue-Saturation controls

The Color Warper Interface

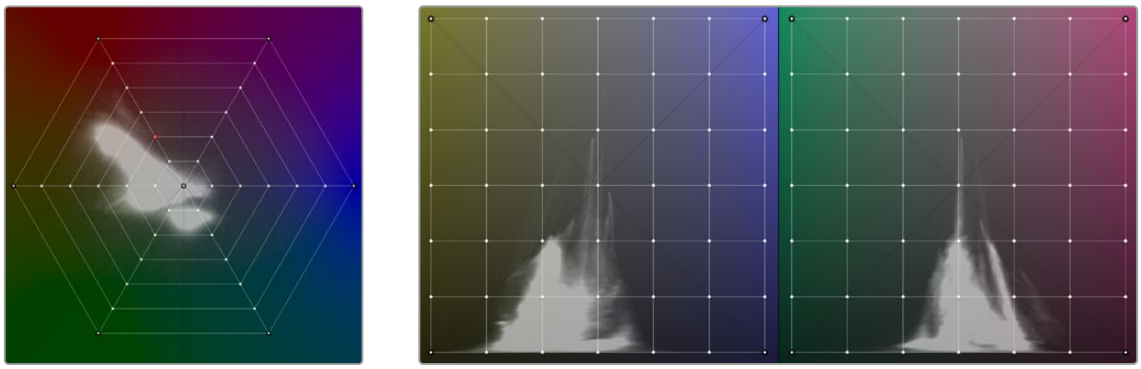
You can either use the Color Warper as it appears docked into the middle palette area, or you can click the Expand button to open the Color Warper into a floating window that you can make as large as you like, giving you more detailed control of dense grids of control points. For convenience, the examples in this chapter show the Color Warper side-by-side with the Viewer, in a floating window. While the Color Warper is open in its own window, the Color Warper palette button in the toolbar turns into a “re-docking” button, clicking it puts the palette back in the palette area below.

(Left) Clicking the Expand button opens the Color Warper into a floating window, (Right) Clicking the Re-docking button in the palette toolbar puts the palette back.

There are two overall regions of the Color Warper palette. At the left, the grid area has the actual warping grid with points you manipulate to make adjustments, while controls underneath let you choose the resolution of the grid and the color space in which it works. At the right, the control area provides all the tools, range controls, and feathering controls that are available for manipulating the warping grid in a variety of highly specific ways.

Using the Grid Controls to Manipulate Color

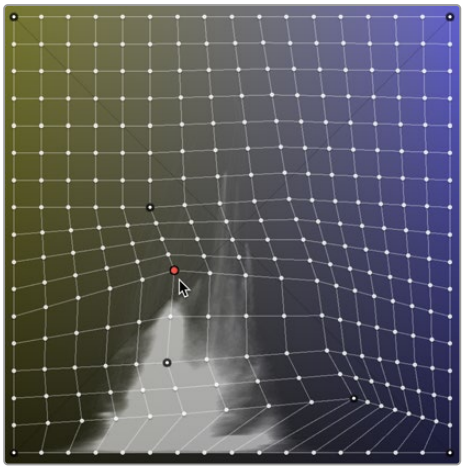
This palette has two modes; each lets you manipulate the colors of the image in different ways, and each has a different style of grid used for warping the different color channels that are affected. Learning how to manipulate the color warping points of each of these grids is central to understanding how this palette works.



(Left) The radial grid in Hue-Saturation mode,
(Right) The two rectangular grids in Chroma-Luma mode

Dragging to Warp Colors

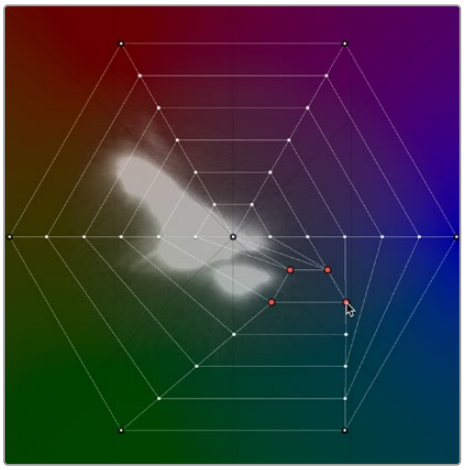
Despite the different shapes, each of these grids are manipulated in similar ways. Dragging a control point alters whatever color corresponds to that point, while the colors that surround this dragged point are also adjusted proportionally according to their location between the point being dragged and surrounding points that either (a) aren’t affected, or (b) are locked into place. Locked points prevent the colors at those points from being changed. By locking some parts of a grid and dragging other parts, you can create sophisticated hue-specific adjustments.



The orange control point has been selected and dragged to make an adjustment. Control points with black outlines are locked in place and help prevent control points on the opposite side from being moved. All other control points between the selected and locked control points are stretched or squished depending on the selected point's adjustment.

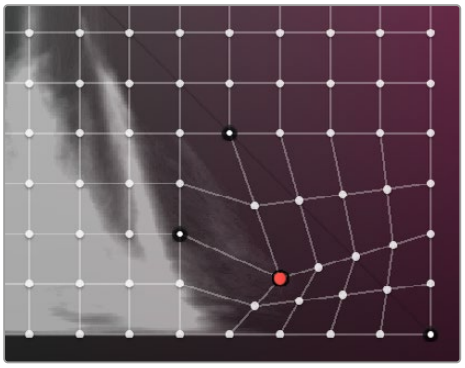
The image above shows the three states of control points in the grid:

- **Orange:** *Selected* points appear orange. You can select multiple points by Command-clicking multiple points, by dragging a bounding box over multiple points, or by using the draw selection tool to click and draw over any points you want to select. Once you've selected and moved a control point, it becomes locked to keep that adjustment in place.



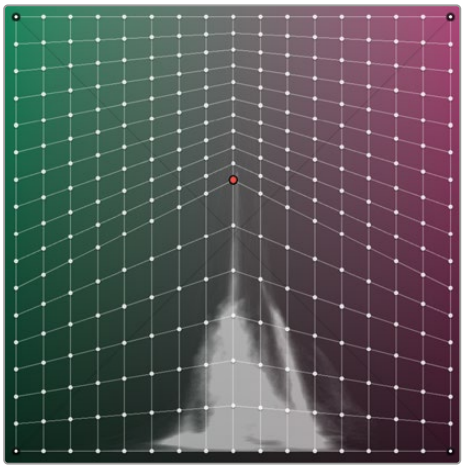
Selected points appear orange; in this example four points are selected to move them all together.

- **Outlined:** White control points with a black outline are *locked*. Locked points do not move automatically when nearby points are dragged, so locked points are important for preventing specific colors you don't want altered from being changed, as well as for saving changes to points that you've adjusted. All adjusted points become locked. The outer corners of the Chroma-Luma grid are locked, as is the outer ring and center point of the Hue-Saturation web.



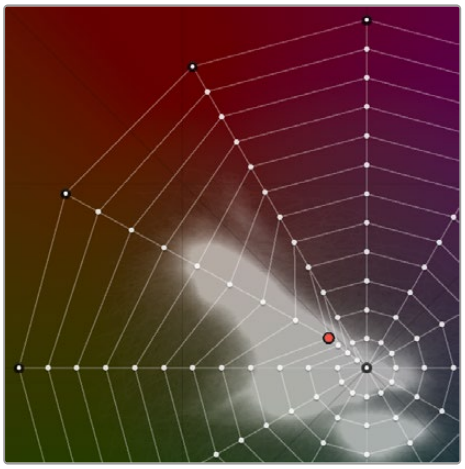
Locked points with black outlines keeping other colors in the image from being adjusted by the selected point

- **White:** White control points are neither selected nor locked, and will be stretched or squished when adjacent control points are moved.



Unlocked control points between a selected point and locked points (in this case the corners of the grid) will squish and stretch to warp an entire range of color as you drag.

While control points work much the same in either the Hue-Saturation or Choma-Luma modes, there are some important differences. The radial “spokes” of the Hue-Saturation wheel don’t influence neighboring spokes, so any adjustment you make to a control point on one spoke only affects the colors that fall between it and the two neighboring spokes that surround it. This means it’s not necessary to lock control points on neighboring spokes of this wheel-shaped grid to prevent them from changing.



Adjustments made to control points on one “spoke” of the Hue-Saturation wheel grid don’t affect those on neighboring spokes, which act as if they’re locked, even though they’re not.

Both the Hue-Saturation and Chroma-Luma warper grids lock the outer boundary of the grid. You can still drag these points to adjust them, but they can’t be unlocked and they won’t move automatically when you adjust other control points. The Hue-Saturation grid has an additional point locked right in the center, which keeps the neutral colors (black through gray and white) neutral.

TIP: Dragging the locked center point of the Hue-Saturation grid lets you alter the color of the white point, while proportionally warping all other colors in the image to smoothly accommodate this change. This can be the starting point of a lot of different looks.

Previewing Which Colors Are Warped By Each Control Point

If you press and hold the Option key while you click on a control point in the warp grid, you get a preview in the Viewer of which colors that control point will affect. Affected pixels appear in color against black, which represents all pixels that will remain unaffected by that control point.

Holding the Option key down while clicking a Color Warper control point shows a preview of affected pixels against black.

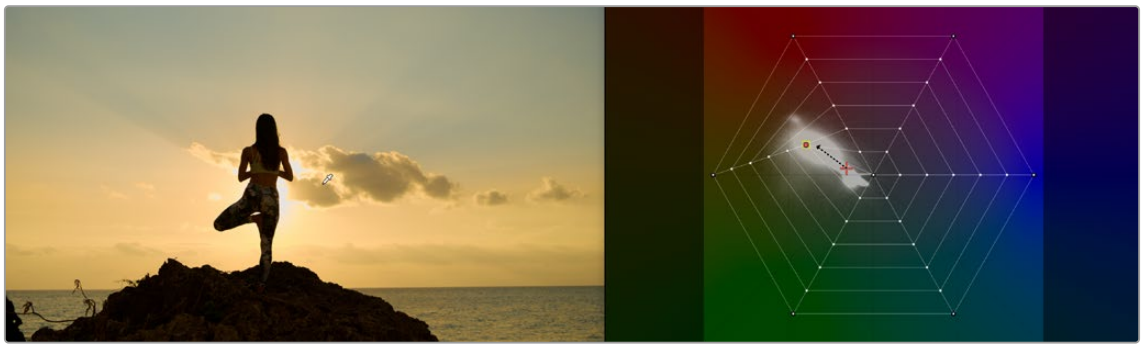
Sampling to Warp Colors

While it's important to learn how control points in the grid are manipulated, the most intuitive way of working with this control is to use the pointer to click within the Viewer to sample a color you want to adjust, hold the pointer button down, and then drag to adjust the color.

When moving the pointer in the Viewer, you'll see a crosshairs moving around the warping grid that shows you the exact color on the vectorscope graph, while a yellow box indicates the control point that's closest to the color you're sampling that will be selected if you click. In the following example, positioning the eyedropper over the sky shows that clicking will select a control point close to the center of the grid.

Moving the pointer in the Viewer shows a preview in the warping grid of which control point you'll select were you to click.

Clicking and dragging selects and then moves the control point corresponding to that color in the Viewer. As you drag the pointer, you'll see the selected control point move in the same direction as the mouse while the colors of the image update in real time to show the adjustment you're making. Meanwhile, an arrow in the grid shows you the delta of the current adjustment. Moving a selected control point to another hue in the grid warps the original color to the new color.



Clicking and dragging moves the control point corresponding to that color in the grid to adjust the color and locks it into place.

You can also lock control points by sampling the image. Hold the Command and Shift keys down, and then click on the color or colors you want to lock in the warp grid to prevent them from being changed. This makes it easy to work directly in the Viewer to lock colors you don't want to change, before adjusting other colors that you do want to change.

In the following example, Command-Shift-clicking on the woman's shoulder locks the yellowish highlights falling on her uniform in place. Then, clicking and dragging a highlight on her face lets us push the highlights towards teal without losing the warmer highlights on her shoulder, all by sampling directly in the Viewer.

(Top) Command-Shift-clicking to lock the closest control point to a color on the warping grid you don't want to change, (Bottom) Warping a neighboring color while the control point you just locked keeps that part of the image from changing

Resetting Grid Points

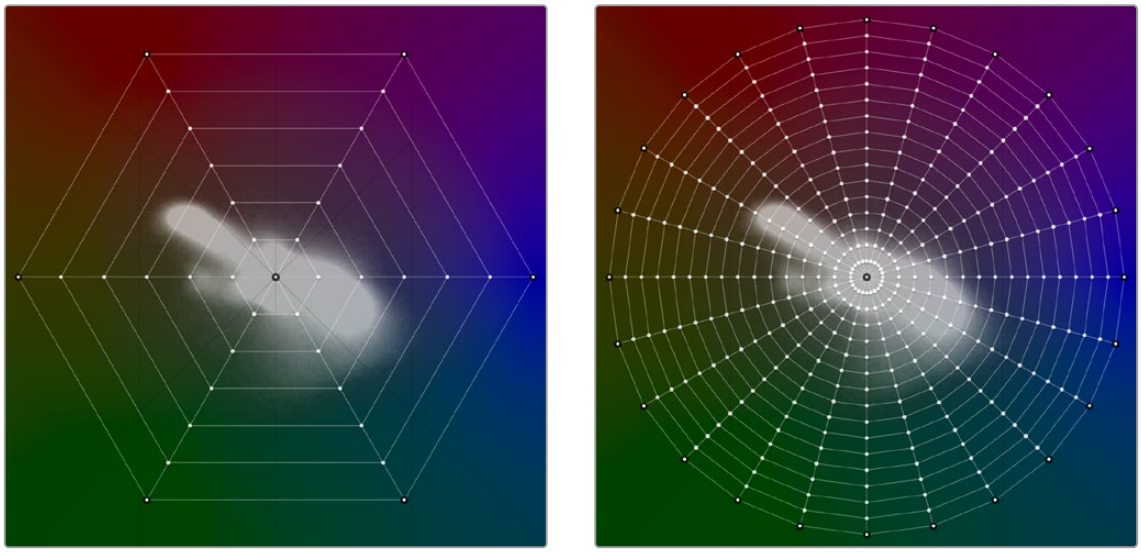
If, at any point, you adjust a point that you want to reset, simply right-click on that point to de-lock and reset it.

Grid Resolution Affects The Specificity and Quality of Adjustments

You can change the resolution of the grids in either Hue-Saturation or Chroma-Luma modes, using the controls at the bottom of the Color Warper palette, underneath the grid itself. Separate drop-down menus let you choose the resolution of control points for hue and saturation, or for chroma and luma separately, although by default they're linked together.

The two resolution controls found underneath the grid controls

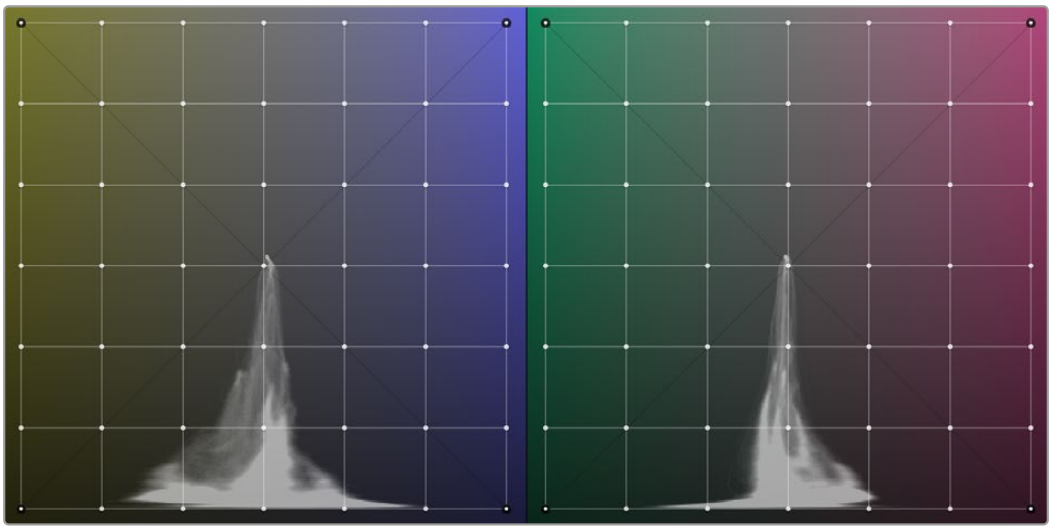
By default, the Hue-Saturation grid has a resolution of 6x6, which is the lowest resolution available. The Chroma-Luma grid defaults to 6x6, but can be set lower, to 4x4. Low resolution warping grids make it easy to create broad color adjustments affecting large ranges of analogous color with smooth results. Additionally, lower quality media that's 8-bit, with 4:2:0 chroma subsampling, and/or highly compressed benefits from lower resolution warping grids to avoid artifacts and keep color adjustments smooth.



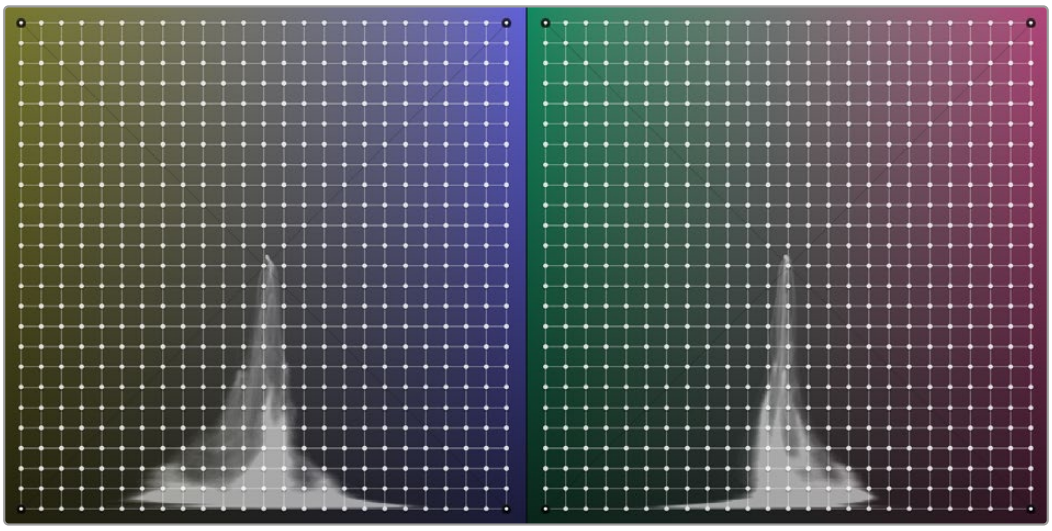
(Left) The Hue-Saturation grid set to a resolution of 6x6,
(Right) The Hue-Saturation grid set to a resolution of 24x16

On the other hand, higher resolution grids let you make more specific adjustments to tighter ranges of color. However, this approach is more useful in projects using high quality media (10- or 12-bit, 4:2:2 or 4:4:4 chroma subsampling, and minimally compressed) to avoid unwanted artifacts. If you're using high-quality media, you'll find you can use the Color Warper to make incredibly specific adjustments.

You can set the default Hue and Saturation grid resolutions in the Color Warper's Option menu by choosing Default Hue Resolution or Default Saturation Resolution and selecting your preferred resolution from the drop-down menu.



The Chroma-Luma grid set to a resolution of 6x6

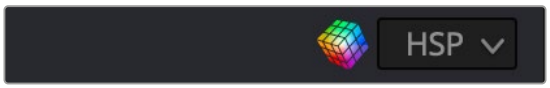


The Chroma-Luma grid set to a resolution of 24x24

NOTE: If you make adjustments with the grid at one resolution, it's possible to change the grid to a higher or lower resolution, and your adjustment will be interpolated to fit the new grid resolution, although the resulting adjustment may change a bit.

You Can Warp Color in Different Color Spaces

A drop-down menu at the bottom right of the warping grid lets you choose which color space to use for manipulating the colors of the image. Different color spaces project the colors of the image into the two-dimensional warping grid in different ways, and some may make it easier to manipulate a particular image in the way you want by spreading out different ranges of color more widely.



The color space found underneath the grid controls

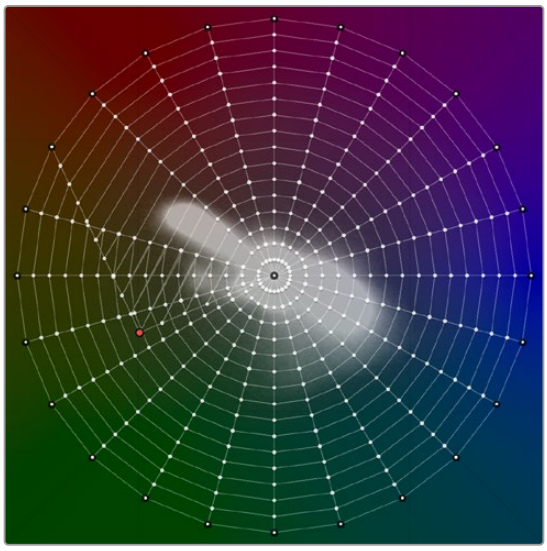
The available color spaces are:

- HSV
- HSL
- HSY
- HSP

Hue – Saturation Controls

As the name implies, the Hue-Saturation mode lets you alter hue and saturation simultaneously. For most people, this is likely the most intuitive mode in which to work as the range of hues and saturation in the image is represented radially, just like the Vectorscope; in fact a Vectorscope graph of the image appears underneath the “wheel” grid of control points used to manipulate color.

By default, dragging any point of this grid changes the colors immediately surrounding that point that are between the point being manipulated and adjacent “spokes” of the radial grid that either aren’t influenced by that point, or are locked into place. In fact, you can pull these radial control points well past the boundary of adjacent spokes of the grid to warp those colors to entirely different hues.



The selected control point being adjusted doesn’t affect points on adjacent columns of control points that stretch from the outer ring to the center of this control, even when the dragged point is moved all the way past.

When manipulating control points to alter color, adjustments are similar to pushing color around a color wheel. Moving a control point radially around the circumference of the grid changes the hue of the colors corresponding to that control point. Moving a control point closer to the center desaturates those colors, while moving a control point closer to the edge of the grid increases the saturation of those colors.

The following sections describe how the different tools available in this mode work to let you manipulate these radial control points in different ways.

Tools

Each of the available tools let you manipulate control points on the warping grid in different ways when you click on them.

- **Selection Tool:** The default tool mode. Selecting this tool lets you select control points either individually (by clicking on a single point or command-clicking multiple points) or collectively by dragging a bounding box over multiple points, and you can right-click on control points to de-select, unlock, and reset them. You can also Shift-click with this tool to lock points into place without moving them. This is the most useful tool to use when manipulating the image by clicking and dragging in the Viewer to sample a color and adjust it at the same time.
- **Draw Selection:** Selecting this tool lets you make a selection of control points by clicking and dragging to draw over all the points you want to select. This is good for making large, but specific, selections of points.
- **Pin/De-Pin:** Selecting this tool lets you pin multiple control points by either clicking on them or by clicking and dragging to draw over all the points you want to pin/de-pin.
- **Pull Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to pull all neighboring control points towards where you clicked. This can be used to reduce color contrast within a specific range of colors.
- **Push Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to push all neighboring control points within a particular proximity away from where you clicked. This can be used to increase color contrast within a specific range of colors.

Modifiers

Each of the Modifier buttons let you manipulate selections and selected control points on the warping grid in different ways immediately upon clicking each button.

- **Increase Falloff/Smooth Selection:** If you've selected one or more control points, clicking this button expands the selection to include all adjacent control points surrounding the selection.
- **Decrease Falloff/Smooth Selection:** If you've selected a group of control points, clicking this button shrinks the selection by deselecting the outermost ring of selected control points, leaving the inner control points selected.
- **Invert Selection:** Clicking this button selects all unselected control points, and de-selects all selected control points. This is useful when you want to make separate color adjustments to both specifically selected halves of the warping grid.
- **Convert Selection to Pin:** Clicking this button pins all currently selected control points.
- **Select/Pin Column:** If you have one or more control points selected, clicking this button expands the selection to include all points on every column that have at least one selected point.
- **Select/Pin Ring:** If you have one or more control points selected, clicking this button expands the selection to include all points on every ring around the center that have at least one selected point.
- **Select/Pin All, Deselect/Pin All:** Clicking this button toggles the selected state of the entire warping grid on or off.
- **Reset Selection/Pins:** If you have one or more control points selected, clicking this button resets their position to the original default position in the warping grid, without de-selecting them.

Range

The Range control is a fast method of selecting multiple control points corresponding to a specific range of colors.

- **Range:** A gradient shows the range of hues currently being presented in the warping grid. Dragging the left and right handles of the Range control selection box lets you automatically select all control points corresponding to the hues that appear within the selection box. This is a fast way of selecting all points within a range of colors for uniform manipulation.

Auto Lock Controls

The Auto Lock controls enables DaVinci Resolve to automatically lock a border of control points surrounding any control point you select and adjust, which makes highly-specific color adjustments easier to accomplish.

- **Auto Lock:** Enables and disables this behavior.
- **X Points Border:** Lets you set how many points away from the control point you're adjusting the border of locked control points that restricts your adjustments is. How large an area this ends up being depends on how many points you choose, and on the resolution of the warping grid. At higher grid resolutions, the same points distance isolates a smaller region of color.

Smoothing Controls

The smoothing controls let you "ease off" an adjustment you've made by progressively moving one or more selected control points towards their original default position in the warping grid.

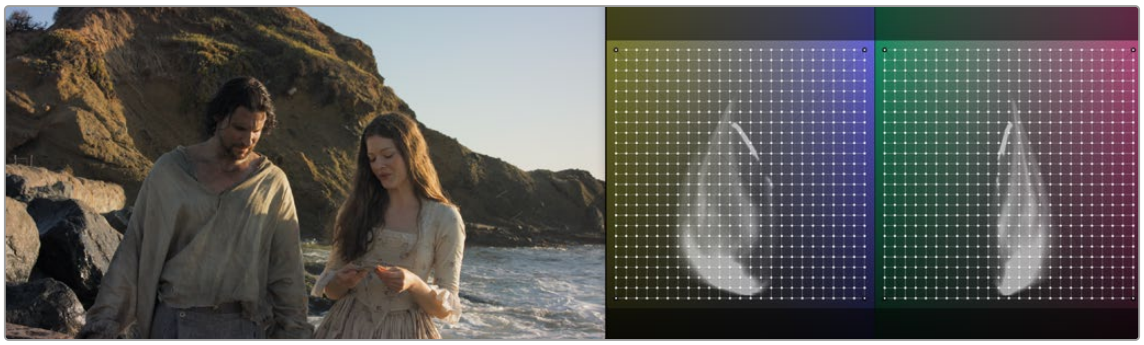
- **Smooth Chroma:** Each click of this button rotates the angle of selected control points around the circumference of the circular warping grid towards their original position, bringing the hue of the adjusted colors closer and closer to the original hues of the image. Saturation is unaffected.
- **Reset Chroma:** Resets the angle of all selected control points to the original hues of those control points. Saturation adjustments are unaffected.
- **Smooth Saturation:** Each click of this button moves the position of a control point closer to its original position relative the center of the circular warping grid, thus bringing the saturation at that point closer to the original image saturation of the node's input. Hue is unaffected.
- **Reset Saturation:** Resets the distance from the center of all selected control points to the original image saturation at those control points.
- **Reset Luma:** Resets luma to the original image values.

Chroma – Luma Controls

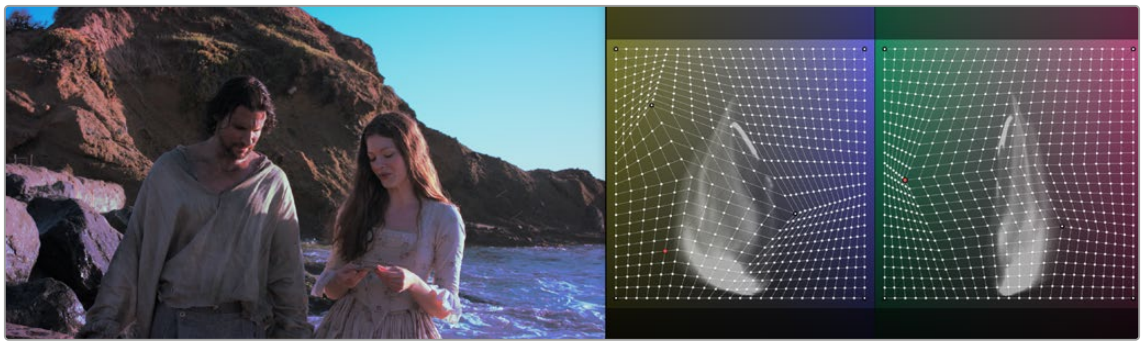
The Chroma-Luma mode lets you alter the hue and lightness of colors in the image simultaneously. This may not feel like a particularly intuitive way of working, as the grid controls are overlaid on colors projected as different sides of an RGB cube. However, this enables some powerful adjustments once you get the hang of how multiple adjustments interact in this mode, as well as the power of locking control points to limit your adjustments to specific areas of the two grids.

Whether you're sampling the image or manipulating the control points of this grid directly, dragging any point of this grid changes the color of the image corresponding to that point. Vertical adjustments change lightness, where up makes that part of the image lighter, and down makes that part of the image darker. Horizontal adjustments change hue, depending on which range of hues are shown in the two Chroma-Luma warping controls, and which of these you're adjusting.

By default, only the outer four corners of this control are locked, so any adjustment you make to any control point pushes and pulls all the other colors throughout the image, depending on your adjustment. Working this way, multiple adjustments to multiple colors gradually pins different colors into place, with each adjustment warping the colors falling in between to maintain a smooth transformation from one adjustment to the next. This can be a good way to make an overall stylistic adjustment to the image.



The original image



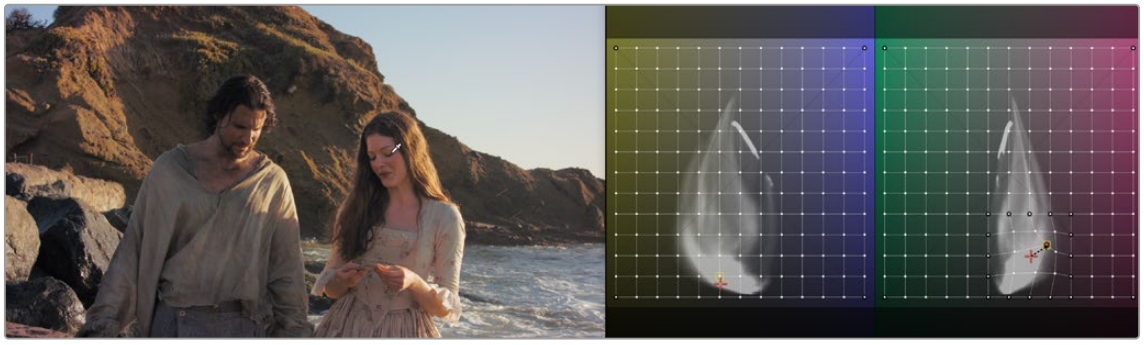
The result of making multiple interacting color adjustments across the entire Chroma Luma grid

Another approach to using this mode is to make more targeted corrections by manually locking different colors in the image that you don't want to adjust. You can do this by using the Selection tool and Shift-clicking any value in the Viewer, or by Shift-clicking any control point on the grid control. By locking colors you don't want to change, you can focus on manipulating a more specific range of colors without altering the entire image.

Alternately, this is where the Auto Lock controls really shine. When you turn these on, you can choose the type of region you want to affect (vertical column, horizontal row, or a square region), then choose how large a region of color you want to manipulate (one or two points away from the point that's selected). Keep in mind that the current resolution of the warping grid also has an effect on how large the resulting region of color will be. Lower resolution grids will let you manipulate larger regions of color, while higher resolution grids will let you adjust a more narrow range of color.

The Auto Lock controls let you make highly targeted adjustments to specific sections of the warping grid.

Once these controls are enabled, simply clicking once on the image or warping grid selects a control point and automatically locks off the region of the grid you want to focus your adjustment on. In the following example, a medium-resolution grid is used in conjunction with the Auto Lock controls set to lock a 2-point rectangular region. So, clicking on the skin of the woman's face and dragging adjusts a section of available reds within the locked-off region of the grid.



Making a targeted color adjustment to a locked-off region of the Chroma Luma grid

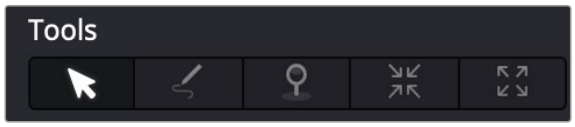
The following sections describe how the different tools available in this mode work to let you manipulate these radial control points in different ways.

Axis Angle

When you're in Chroma-Luma mode, an additional control appears underneath the warping grids, a slider named Axis Angle. Dragging this slider to the left or right changes the range of hues in each of the two warping grids that's presented, letting you manipulate different ranges of color.

Tools

Each of the available tools let you manipulate control points on the warping grid in different ways when you click on them.



The Tools buttons

- **Grid 1/Grid 2 tabs:** Since the Chroma-Luma controls expose two grids representing two different ranges of hue and luma, these two tabs let you choose which grid will be manipulated when you sample the image in the Viewer, as well as which grid the Tools controls affect.
- **Selection Tool:** The default tool mode. Selecting this tool lets you select control points either individually (by clicking on a single point or command-clicking multiple points) or collectively by dragging a bounding box over multiple points. You can also Shift-click with this tool to lock points into place without moving them, and you can right-click on control points to de-select, unlock, and reset them. This is the most useful tool to use when manipulating the image by clicking and dragging in the Viewer to sample a color and adjust it at the same time.
- **Draw Selection:** Selecting this tool lets you make a selection of control points by clicking and dragging to draw over all the points you want to select. This is good for making large, but specific, selections of points.

- **Pin/De-Pin:** Selecting this tool lets you pin multiple control points by either clicking on them or by clicking and dragging to draw over all the points you want to pin/de-pin.
- **Pull Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to pull all neighboring control points towards where you clicked. This can be used to reduce color contrast within a specific range of colors.
- **Push Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to push all neighboring control points within a particular proximity away from where you clicked. This can be used to increase color contrast within a specific range of colors.

Modifiers

Each of the Modifier buttons let you manipulate selections and selected control points on the warping grid in different ways immediately upon clicking each button.

The Modifier buttons

- **Increase Falloff/Smooth Selection:** If you've selected one or more control points, clicking this button expands the selection to include all adjacent control points surrounding the selection.
- **Decrease Falloff/Smooth Selection:** If you've selected a group of control points, clicking this button shrinks the selection by deselecting the outermost ring of selected control points, leaving the inner control points selected.
- **Invert Selection:** Clicking this button selects all unselected control points, and de-selects all selected control points. This is useful when you want to make separate color adjustments to both specifically selected halves of the warping grid.
- **Convert Selection to Pin:** Clicking this button pins all currently selected control points.
- **Select/Pin Column:** If you have one or more control points selected, clicking this button expands the selection to include all points on every column that have at least one selected point.
- **Select/Pin Row:** If you have one or more control points selected, clicking this button expands the selection to include all points on every row that have at least one selected point.
- **Select/Pin All, Deselect/Pin All:** Clicking this button toggles the selected state of the entire warping grid on or off.
- **Reset Selection/Pins:** If you have one or more control points selected, clicking this button resets their position to the original default position in the warping grid, without de-selecting them.

Range

The Range control is a fast method of selecting multiple control points corresponding to a specific range of colors.

The Range control

- **Range:** A gradient shows the range of hues currently being presented in the warping grid. Dragging the left and right handles of the Range control selection box, or dragging within the range control to set both boundaries, lets you automatically select all control points corresponding to the hues that appear within the selection box. Once you've set a range, you can move the range to the left and right by dragging the center of the selection. This is a fast way of selecting all control points within a range of colors for uniform manipulation.

Auto Lock Controls

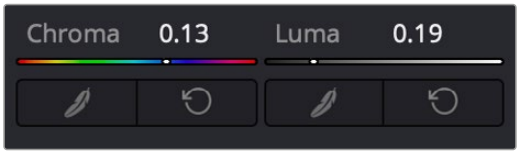
The Auto Lock controls enables DaVinci Resolve to automatically lock a border of control points surrounding any control point you select and adjust, which makes highly specific color adjustments easier to accomplish. These are particularly useful in the Chroma-Luma warping grid.

The Auto Lock controls

- **Auto Lock:** Enables and disables this behavior.
- **X Points Border:** Lets you set how many points away from the control point you're adjusting the border of locked control points that restricts your adjustments is. How large an area this ends up being depends on how many points you choose, and on the resolution of the warping grid. At higher grid resolutions, the same points distance isolates a smaller region of color.
- **Lock Column:** Lets you choose to restrict your adjustment to affect all control points within a particular column of the rectangular Chroma-Luma graph. The width of this column is defined by the border width controls. This is useful when you want to primarily adjust the lightness of a range of colors, while making a small adjustment to hues.
- **Lock Row:** Lets you choose to restrict your adjustment to affect all control points within a particular row of the rectangular Chroma-Luma graph. The height of this row is defined by the border width controls above. This is useful when you want to primarily adjust the hue of a range of colors, while making a small adjustment to lightness.
- **Lock Region:** Lets you choose to restrict your adjustment to affect all control points within a rectangular region surrounding the selected point. The is useful when you want to adjust a targeted region of color that corresponds to a well-defined feature of the image, such as a specifically colored hat, shirt, foliage, or skin tone. Smaller regions will make more specific adjustments than larger regions.

Smoothing Controls

If you've found that you've gone a bit too far with an adjustment and need to back off a little bit, the Smooth controls let you do so gradually, or start over if necessary.



The Smoothing controls

- **Smooth Chroma:** Each click of this button moves selected control points left or right, back towards their original position, bringing the hue of the adjusted colors closer and closer to the original hues of the image. Luma is unaffected.
- **Reset Chroma:** Resets the position of all selected control points to the original hues of those control points. Luma adjustments are unaffected.
- **Smooth Luma:** Each click of this button moves selected control points up or down, back towards their original position, bringing the luma of the adjusted colors closer and closer to the original luma of the image. Chroma is unaffected.
- **Reset Luma:** Resets the position of all selected control points to the original luma of those control points. Chroma adjustments are unaffected.

Chapter 135

Secondary Qualifiers

Secondary correction describes isolating a specific part of the image, or a specific subject, using a key.

Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black).

Keys can be generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte,

> For more information on how to use external mattes, *see Chapter 144, "Combining Keys and Using Mattes."* This chapter focuses on how you can use qualifiers to key a range of color values (similarly to doing a green screen key) in order to create a matte with which to do this kind of isolated adjustment.

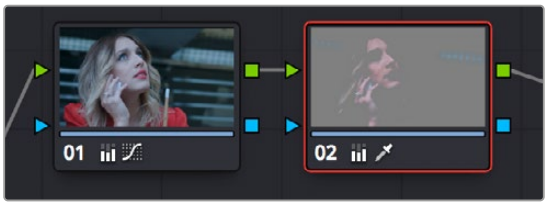
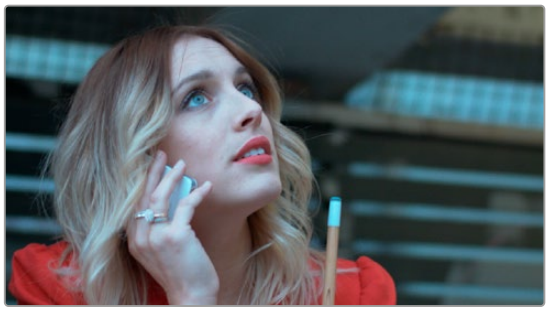
Secondary Qualifiers

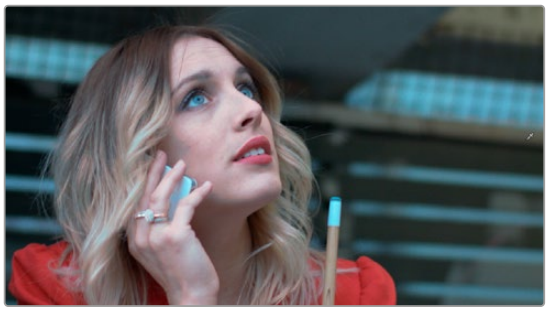
This section covers the use of the Qualifier palette, which lets you pull a 3D, HSL, RGB, or Luma key, with which to isolate the correction you need. The Qualifier controls are fast and flexible when you need to isolate an irregularly shaped subject with a distinct range of color or lightness. Since you're generating a key by sampling the image, there's no need for tracking or keyframing, so in the right situation qualifiers can be your fastest solution. In the following example, the client likes the slightly cool treatment overall, but wishes that the skin tones were a little more vibrant. This is exactly the sort of situation where qualifiers can help out. Adding a second node, and using the 3D or HSL Qualifier to isolate the face makes it relatively simple to add color exactly where you want it.



Adding a second node and using HSL Qualification to isolate the skin tones



The image with a simple primary correction



The final adjusted image

Just about every control in the Color page can be limited using of the Qualifier modes available in DaVinci Resolve. This makes the Qualifier palette a jack-of-all-trades tool with 101 uses. A few practical examples include keying a red element that's too intense for broadcast, in order to darken it or desaturate it; keying a range of green foliage, so you can shift its hue to a more attractive color; keying an actor's skin tone in a commercial, to apply some selective softening to it; or keying a range of sky, in which to add blue.

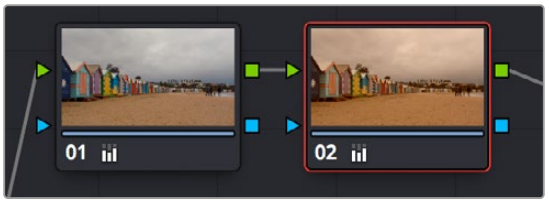
The Qualifier palette is color-space-aware when you're using Resolve Color Management (RCM) or ACES. This enables Qualifiers to create high-quality keys as you would expect, no matter what the color space of the original media is, or what Timeline Color Space you're using, for both SDR and HDR mastering. This makes Qualifier isolations easier, and a more consistent experience no matter what your workflow happens to be.

Adding a Secondary Operation to the Node Editor

Any node can be switched between functioning as a primary correction, where the adjustments you make affect the entire image, and a secondary correction, where you're adjusting a specific element in the scene. The only difference is that nodes being used for secondary corrections are limited using a qualifier, Power Windows, or an external matte.

If you're planning to add a secondary operation to the current grade, you'll need to first add another node in the Node Editor. When pulling a key to qualify part of the image, it's important to understand that you'll be sampling the YRGB values being fed to that node from any previous nodes in the tree. That means that the state of the image being fed to a node you're qualifying affects the key you're pulling.

For example, if the image coming out of Node 1 is well saturated and has a neutral color balance with a wide range of colors, but the image coming out of Node 2 applies a low saturation, monochromatically orange color wash, you may find it more difficult to pull a detailed key from Node 2 than you would from Node 1.



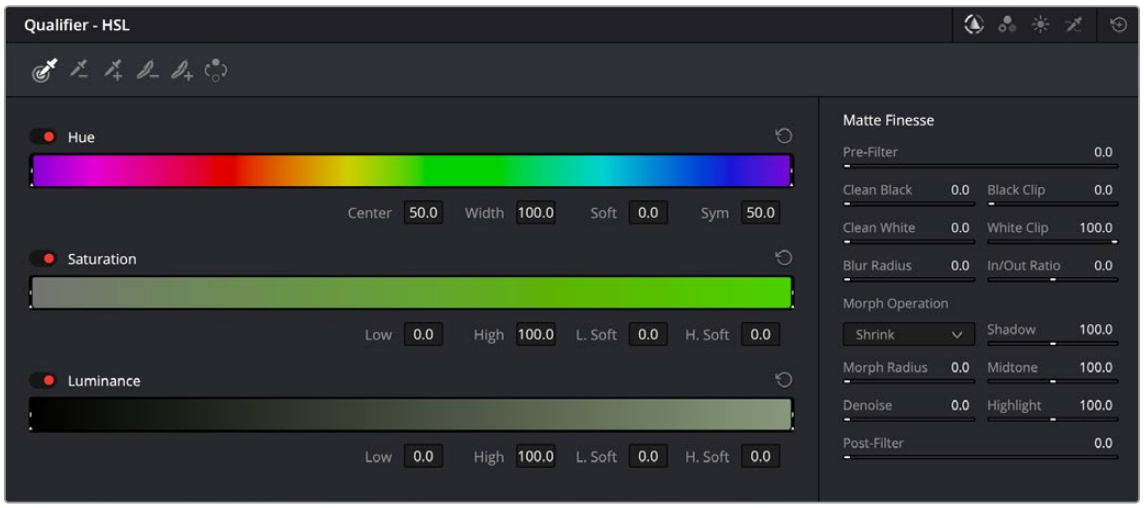
Choosing your battles–the image coming out of Node 1 will be easier to key than the highly stylized image coming out of Node 2

This is important because you have the flexibility of determining from what image you want to try pulling a qualified key. By connecting the node that's outputting the best YRGB image for the key you're trying to create to the node you're qualifying, you can control what you're keying.

> For more information about choosing which node to use for setting up a qualifier, *see Chapter 144, "Combining Keys and Using Mattes."*

The Qualifier Interfaces

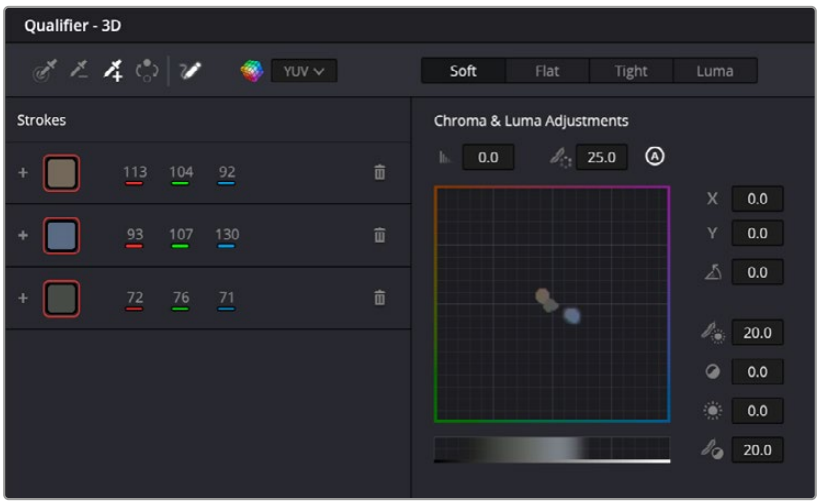
The DaVinci Resolve Qualifier palette interface is straightforward. To the left, graphical controls above numeric parameters let you manually adjust what ranges of each color component contributes to the key you're creating. To the right, Selection Range tools below let you define a key by sampling pixels of the image using the pointer, while below a set of Matte Finesse parameters let you alter the shape of the key that's been pulled.



Qualifier palette with HSL controls selected

The default qualification mode is the HSL Qualifier, which uses three color components, hue, saturation, and luma, to define a key. However, you can also use the RGB or LUM (Luma) qualification modes to pull keys using other combinations of color components. The LUM qualifier mode, in particular, lets you make targeted adjustments to specific ranges of image lightness. This is a technique employed by many colorists to alter color temperature within a specific range of image highlights or shadows.

Alternately, you can use the 3D qualifier to quickly and easily pull well-refined keys by drawing lines to sample colors from the image that correspond to volumes of color within a three-dimensional gamut. While the underlying technology is sophisticated, all you have to do is to draw blue lines to sample colors you want to isolate, or red lines to sample colors you want to subtract from the isolation you're creating, all of which automatically generate a high-quality key. Each line you draw adds a sample to the selection list; you can turn each sample off and on to evaluate its contribution to the resulting key, or delete samples that don't make a positive contribution.



The 3D qualifier

No matter which qualifier mode you use, the Matte Finesse controls make it easy to refine the resulting key to be even cleaner and more usable. In some instances, you can even take a marginal key that would otherwise be unusable, and squeeze it into something useful using the Clean Black, Clean White, and Blur Radius controls.

Which Qualifier Do I Use?

The Qualifier palette's four modes offer you the flexibility to use the best keyer for the job when it comes to isolating a range of color or brightness values. In some cases, keys that are difficult to pull using some modes are easier to pull using others. Here's a brief summary:

HSL: In many instances, the HSL keyer is not as immediately accurate as the 3D keyer, and will include a broader portion of the image for any given sample. On the other hand, if the 3D keyer is not giving you satisfactory results for a particular shot, the HSL keyer can sometimes do a better job. Because of its interface, the HSL keyer makes it easier to "fine-tune" the range and softness of each individual color component that's sampled, in order to improve the result. The HSL keyer also gives you the option of disabling color components that you don't want to contribute to the final key, so that you can pull a saturation-only key, or a hue-only key, for instances where that may solve the issue at hand.

RGB: The RGB keyer shares many of the limitations and advantages of the HSL keyer, but since you're sampling and adjusting red, green, and blue color components, the specificity with which you can fine-tune the resulting key works much differently.

LUM: The LUM keyer works specifically to isolate parts of the image based on image tonality, lightness, or darkness. This is the perfect tool when you're trying to isolate highlights or shadows in the image, which let you solve a multitude of different creative and technical issues. The LUM keyer is identical to using the HSL keyer with the Hue and Saturation qualifier controls turned off.

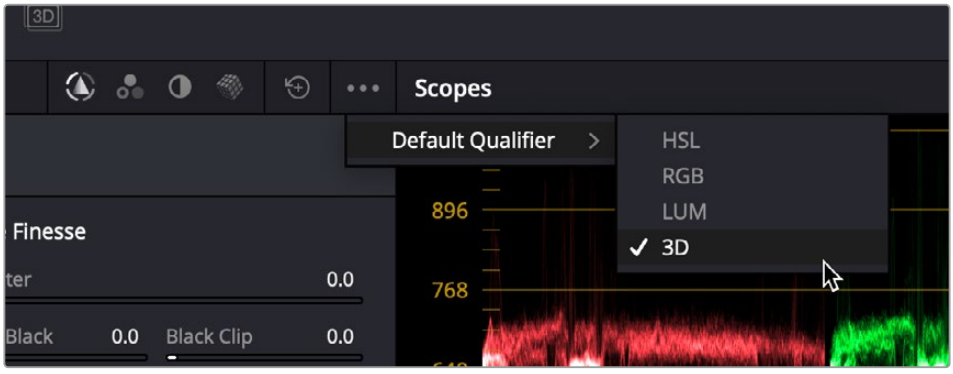
3D: The 3D keyer is a good one to start with if you're trying to isolate a range of color such as a blue shirt, a cyan sky, a performer's skin tone, or the orange leaves of a tree in autumn. Its interface of drawing lines over the part of the image you want to isolate, coupled with its high quality and extreme specificity, make it a fast and accurate tool to use in a variety of circumstances. However, the 3D keyer always samples every color component of the image; it's not useful when you want to isolate specific color components, such as luma only, or hue and saturation without luma. The 3D keyer's greatest strength, the speed with which you can sample areas of the picture to include (or exclude) from the final key, is also occasionally a weakness with images where your initial samples aren't giving you satisfactory results, because there aren't many ways to fine tune the key as it's being generated (although you can manipulate the result). On the other hand, for most images you would want to qualify, two or three samples is all you need, in conjunction with using the Matte Finesse controls to adjust the resulting key. If you need to do some compositing in the Color page, the 3D keyer also does an excellent job doing blue and green screen keying to create transparency, and has a built-in Despill control as well.

The following two sections provide an overview of how to use the 3D and HSL keyer modes in DaVinci Resolve.

Set the Default Qualifier Mode

You can set your favorite qualifier to open as the default when you apply a qualifier on a new clip on the timeline. This can save a significant amount of clicks over the course of a project. As expected, if a qualifier other than the default has been applied to the clip, that qualifier will open instead.

To change the Default Qualifier, click on the Qualifiers (3-dot) Option menu, select Default Qualifier, and choose an option from the list.



Changing the Default Qualifier to 3D, which will now open the 3D qualifier instead of the HSL qualifier on new clips

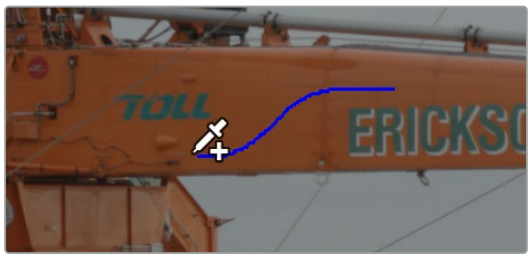
Basic Qualification Using the 3D Qualifier

The 3D Qualifier mode offers a fast, simple way of pulling a key to isolate a range of color in the image, by drawing lines over the parts of the image you want to key. Each line you draw over the image adds to or subtracts from the cloud of values you're carving out of a three-dimensional representation of all available colors; you don't see this representation, but this "under the hood" functionality is what gives the 3D keyer its name.

The 3D keyer is a general-purpose keyer, letting you isolate any color you like. However, the 3D keyer is not good at pulling luma-only keys. If you're looking to isolate a range of luma values in the image, you should use the LUM mode.

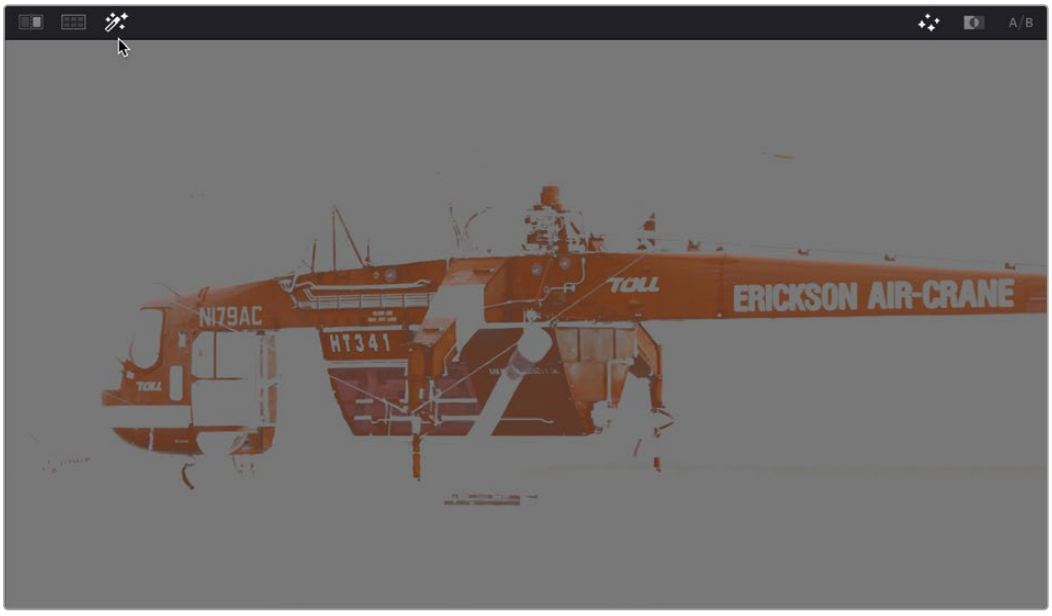
To use the 3D mode to isolate a subject in the Viewer:

1. Open the Qualifier palette, choose the 3D icon in the upper right and click the eyedropper.
2. Click and drag across the part of the image you want to isolate to draw a line. Lines that add to the key are colored blue.



Drawing a line to create a key using the 3D qualifier

3. To see the key you're creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer. As you draw the line, the viewer will update to show your current key in real time.

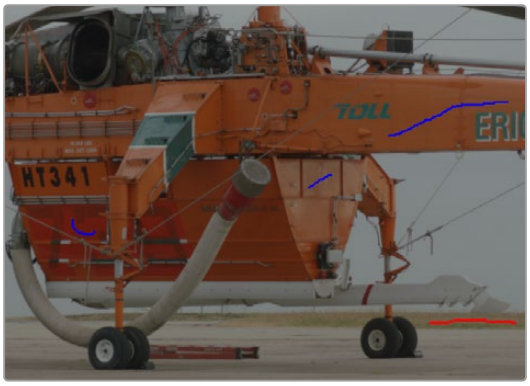


Viewing the key using the Highlight button

4 If necessary, draw additional lines to add more of the image to the key you're creating. Ordinarily, it's a good idea to not to draw more then two or three lines to sample the part of the image you're trying to isolate. A few long strokes are better than several short ones. Ideally, you want the key you're pulling to have a somewhat soft edge, which makes it easier to use the Matte Finesse controls to fine-tune your result later on. If you draw too many lines to sample the image, the result can be a key with hard, jagged edges that can sometimes be more difficult to adjust later on.

A hard-edged key created with three samples

5 Alternately, if there are parts of the image that are included in the key that you want to omit, hold the Option key down and draw a line over these areas. You can see that Option-drawn lines are red, and these subtract areas from the key you're creating. Again, try not to overdo drawing subtractive red lines, as you can end up with an overly hard-edged key that's difficult to adjust using other controls in the next few steps. Additionally, you can still use power windows in conjunction with the 3D qualifier to exclude specific parts of the image.



Blue lines add to the key and a red line subtracts the grass from the key, as seen with the highlight turned off

6 If you find yourself wondering whether a particular sample in the list at left is doing any good, you can click the color patch at the left of any entry in the list to toggle that sample off and on. If you decide you don't need a particular sample, click the trash can button at the right to delete it.

Controls for toggling samples off and on, and deleting them from the list

7 When you're satisfied that the key is good enough to start fine-tuning, stop drawing lines. It's all right if there's a bit of noise, speckling, or if there are small holes in the key you're creating, because you can take care of these using the Matte Finesse controls.

A sampled key that's ready for further refinement

Nearly every key you pull will benefit from some further "post-key" refinement. What this means is that, once you've created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a gray-scale image, to improve the isolated result. This is what the Matte Finesse controls are for.

Matte Finesse controls

8 The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

More information about using the Matte Finesse controls appears later in this chapter.

9 When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the orange of the helicopter will be adjusted using the Hue control to make it blue instead.

Adjusting the orange color of the helicopter to be blue instead

Basic Qualification Using the HSL Qualifier

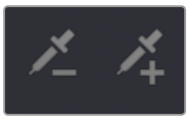
The HSL qualifier is one of the most flexible tools in DaVinci Resolve. Using any combination of sampled hue, saturation, and luma, you can isolate different ranges of color and contrast for specific adjustment. HSL is a general-purpose keyer, meaning you can key any color you like; it's not restricted to blue or green.

The most straightforward way to use any qualifier is to sample the image in the Viewer. A set of four controls let you sample pixels within the image in different ways. When you sample one or more pixels, the Hue, Saturation, and Luma values are analyzed, and set different ranges in each of the Hue, Saturation, and Luma qualifier controls. There are a number of different eyedropper controls available to control how you sample color in the image.

- **Sample Eyedropper:** The first control you use whenever sampling the image. It defines the initial range of the qualification; you must use this tool before any of the others. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.

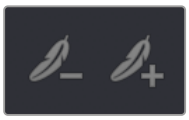
Color
Picker button

- **Add/Subtract Color Range:** These two controls let you add areas of the image to, or subtract them from, the currently selected inner range of values that define the core of the key.
As with the eyedropper, you can click on single pixels, or drag over a range of color.



Add and Subtract
color buttons

- **Add/Subtract Softness:** These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Just like the other controls, you can click on single pixels, or drag over a range of color.



Add and Subtract
qualifier softness

> **NOTE:** When you select one of the sampling controls, it remains selected until you select another sampling control. If you select another clip in the Timeline, then click in the Viewer to sample a key and nothing happens, make sure that you select the Eyedropper control in the Qualifier palette.

If you're working with the DaVinci Resolve onscreen interface, the easiest way to qualify a subject is to use the pointer in conjunction with the sampling controls.

Example image to qualify

To use the HSL Qualifier mode to isolate a subject in the Viewer:

1. Open the Qualifier palette, choose HSL from the mode drop-down, and click the eyedropper.
2. Either click a pixel of the part of the image you want to isolate, or click and drag across a range of pixels within that subject.

Picking to qualify the ocean

3. To see the key you're creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer.

   By default, the area of the image you're isolating appears in color, while the area of the image being excluded appears solid gray.

Viewer image with highlight turned on, isolated region appears in color, omitted region appears gray

Even though the highlight obscures the rest of the image, this doesn't prevent you from using the sampling tools to select pixels you can't see.

4 To subtract from the inner range of the key you're creating, click the minus Color Range control, and click or drag across the portion of the keyed image that you'd like to exclude.

5 To add softness to the outer range of the key you're creating, click the plus Softness control and then click or drag across the portion of the image you'd like to include as a soft edge.

Once you've finished using the range and softness sampling controls to refine the key you're using to isolate the subject, nearly every key you pull will benefit from some further "post-key" refinement. What this means is that, once you've created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a grayscale image, to improve the isolated result. This is what the Matte Finesse controls are for.

Matte Finesse controls

6 The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

   More information about using the Matte Finesse controls appears later in this chapter.

7 When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the saturation has been raised and the color balance changed to make the adjustment obvious.

Altered color balance of the ocean and sky

HSL Qualifier Presets

There is a set of HSL Qualifier presets, or Six Vector presets, that you can use to isolate automatically a predefined wedge of color (green, blue, red, magenta, yellow, or cyan) or chroma intensity (chroma light, chroma dark, or both). These presets are available either from the Color > Presets menu, or using the DaVinci Resolve Advanced control panel.

Selecting one of these presets automatically sets the HSL Qualifier to the corresponding range or color or lightness. Afterwards you can continue modifying the HSL Qualifier to suit your purpose.

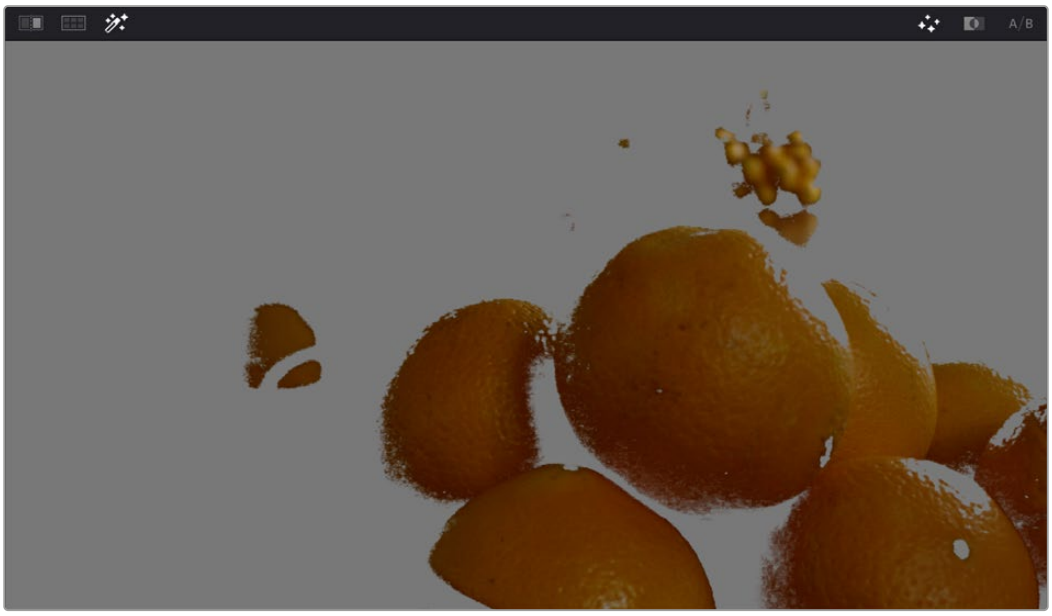
The Color > Presets menu

Using Highlight to See What You're Isolating

The Highlight control at the top of the Viewer (revealed by turning on Viewer Options in the Viewer's Option menu) lets you overlay a representation of the key you're creating over the current image in the Viewer. Overlays are also mirrored to your video output, so they'll show up on an external display as well, in the event that you're hiding the onscreen Viewer.

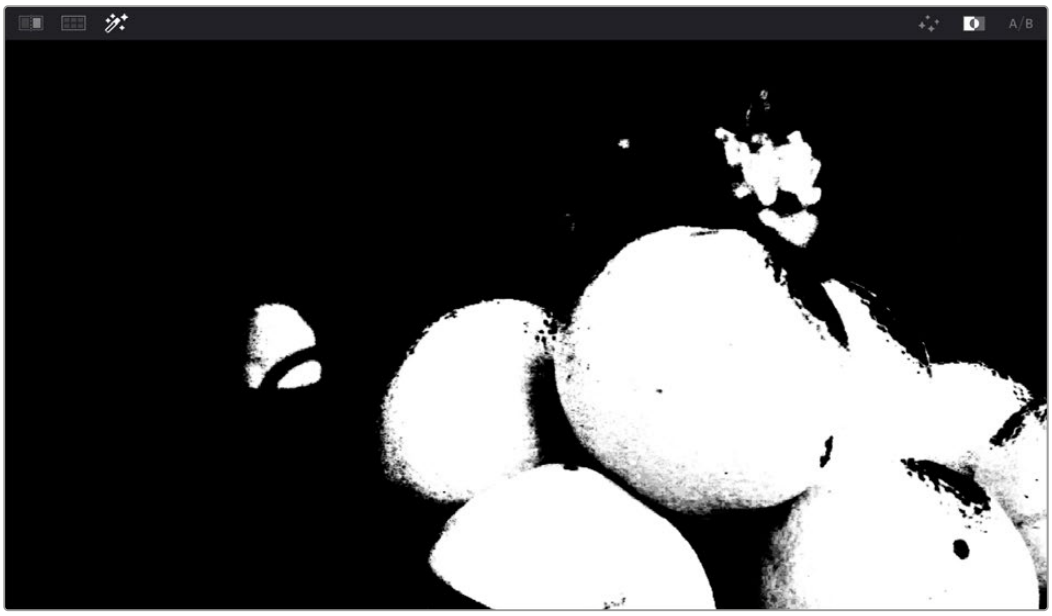
There are two types of highlights with which you can evaluate a qualification you're creating. Each is useful for different tasks.

- **Flat-Gray:** The default highlight that DaVinci Resolve uses shows the selected portion of the image with the original colors, and the unselected portion of the image with a flat gray. It is useful for seeing the subject you're isolating even while you're adjusting the Qualifier controls, which lets you also see the color or contrast adjustments you're applying at the same time.



Oranges qualified and highlighted

- **High-Contrast:** Pressing Option-Shift-H, you can show what's called a "high-contrast" highlight, which should be familiar to you if you've used other color correction applications and plugins; it's a more typical display wherein the selected portion of the image is white, and the unselected portion of the image is black. The high-contrast highlight is useful in situations where you need to eliminate holes in a key, or evaluate how "chattery" a key is since irregularities are easier to spot when divorced from the original image.



High-Contrast B&W highlighting

To enable or disable a highlight, do one of the following:

- In the Viewer Options toolbar at the top of the Viewer, click the Highlight control, and choose the type of highlight you want from the buttons that appear at the right.
- Choose an option from the Highlight submenu in the Viewer's option menu; a regular Highlight is Shift-H.

To enable or disable a high-contrast highlight, do one of the following:

- Choose Highlight > Highlight BW (Option-Shift-H) from the Viewer's option menu.

To make high-contrast black and white the default highlight:

1. Open the Preferences > User > Color window.
2. Check "Mattes display high contrast black and white."
3. Click Save.

   The next time you click the Highlight control in the Qualifier palette, the high-contrast highlight will display.

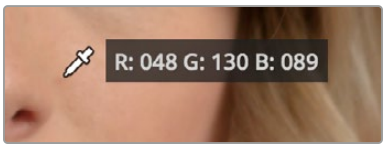
Using Highlight to Solo Nodes

There's one other use of the Highlight control, and that's to solo individual nodes in the Viewer and video out, rather than outputting the sum of the entire node tree. For example, if you're trying to adjust a stack of nodes attached to a Parallel or Layer Mixer node, it's difficult to see what you're doing while adjusting one of the stack of nodes, because only the final result is being output.

However, if you turn on Highlight while you're selecting a node with no key, then only the currently selected node is output, making it easy to view just one node as you adjust it. Just make sure you turn Highlight off before moving on, or you may confuse yourself.

Showing Picker RGB Values

While you're dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the Show RGB Picker Values In submenu in the Viewer's option menu has options for displaying either 8- or 10-bit tristimulus values.



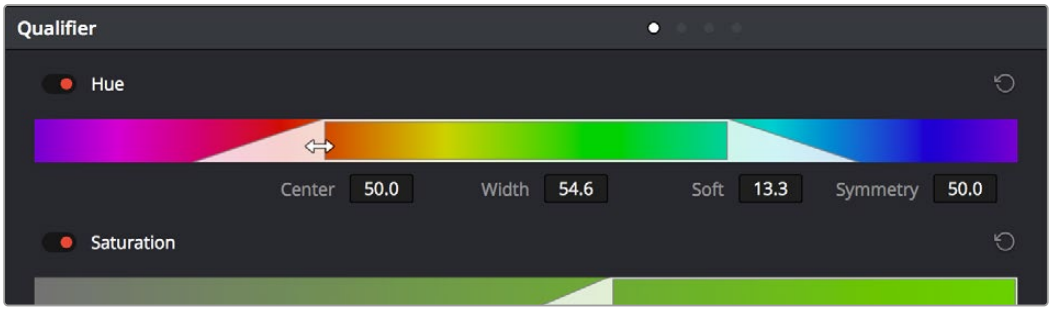
The Color Picker tooltip that appears when you turn on show RGB Picker Values

Qualifier Parameters

Each of the Qualifier modes, except for the 3D qualifier, has parameters that correspond to the relevant color components for that mode, with which you can identify a range and softness, similar to using the sample tools. These parameters can be edited precisely with virtual sliders using the pointer, or using the knobs of a supported grading control panel. However, mouse and tablet users can take advantage of each qualifier's draggable white overlays, for more direct adjustment.

- Drag the left and right edges of any qualifier control overlay to adjust the Low and High values (or the Width value of the Hue control).
- Drag the center of any qualifier control to change the center or to simultaneously change the Low and High parameters together.
- Option-drag the left and right edges of any qualifier overlay to adjust softness.

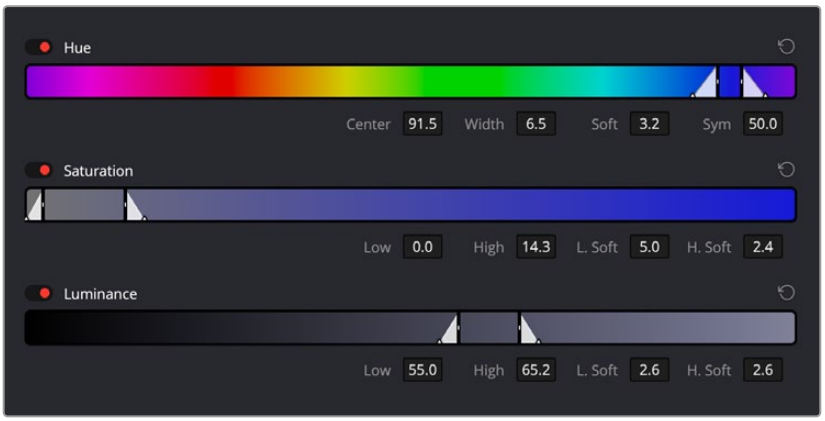
  These draggable controls work for the HSL, RGB, and LUMA qualifier controls (the 3D qualifier works differently).



Draggable qualifier controls

HSL Qualification Controls

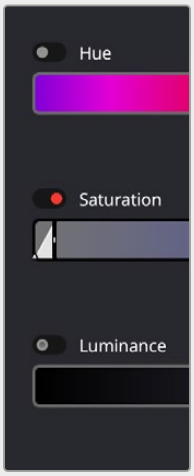
The HSL Qualifier is by far the most versatile mode of the Qualifier palette. It's also the qualifier that's easiest to understand, and the easiest to adjust by hand if you don't feel the need to sample the image. By selecting range and softness for each of three different color components, hue, saturation, and luma, you can isolate a wide variety of colorful subjects, or ranges of image lightness and saturation.

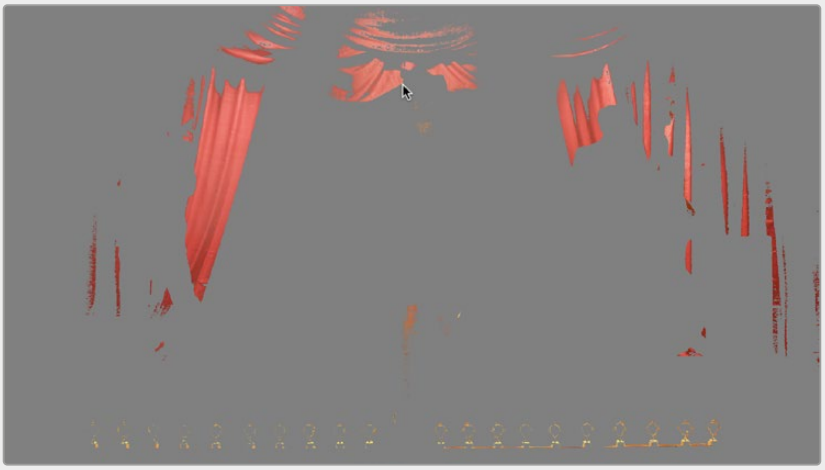


The HSL Qualifier controls in close up

One of the HSL Qualifier's key strengths, and one of its most underutilized features, is that you can enable or disable each of the three HSL components using the Hue, Sat, and Lum buttons, using toggle controls found at the left of each qualifier range control's name. This lets you ignore specific color components, while focusing on others that are more important.

For example, if you're trying to isolate the saturated parts of an image, regardless of the hue or brightness, you can turn off the Hue and Lum qualifiers so that only Sat is used to sample the image.





Qualification with saturation only to isolate the most saturated portion of the picture

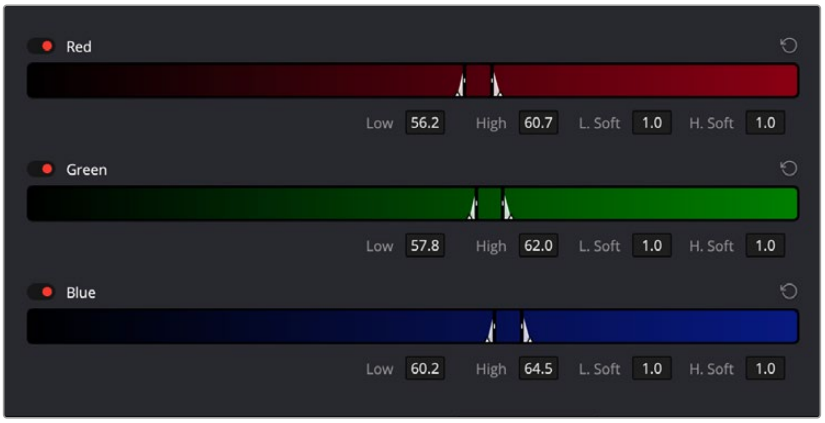
The HSL parameters include:

- **Hue Center:** Defines the center of the range of Hue being isolated.
- **Hue Width:** Defines the width of the range of hue being isolated. Widening or narrowing this parameter widens and narrows the range of hue about the current Hue Center.
- **Hue Soft:** Widens or narrows the falloff at both sides of the currently selected range of hue.
- **Hue Symmetry:** Lets you selectively alter the angle of Hue Soft falloff at either the right or left side. Lowering this parameter makes the softness to the right of the hue range grow steeper. Raising this parameter makes the softness to the left of the hue range grow steeper.
- **Sat Low/High:** Two parameters let you define the upper and lower range of saturation being isolated.
- **Sat Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of saturation.
- **Lum Low/High:** Two parameters let you define the upper and lower range of luma being isolated.
- **Lum Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of luma.

RGB Qualification Controls

The RGB Qualifier mode lets you isolate range and softness in the Red, Green, and Blue channels of an image. While this is not necessarily an intuitive way of manually creating a qualification from scratch, it can provide a different way of isolating potentially trickier ranges of the RGB color space.

If you start by sampling the image, then you can widen and narrow each color channel's isolated range of values. In some cases, you may find it's faster to isolate a specific range of continuous color by adjusting these controls.



RGB qualification controls

The RGB parameters include:

- **Red Low/High:** Two parameters let you define the upper and lower range of the Red channel being isolated.
- **Red Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of red.
- **Blue Low/High:** Two parameters let you define the upper and lower range of the Blue channel being isolated.

- **Blue Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of blue.
- **Green Low/High:** Two parameters let you define the upper and lower range of the Green channel being isolated.
- **Green Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of green.

Luma Qualification Controls

The Luma Qualifier mode simply pulls a key from the Luma channel all by itself. It's identical to the HSL qualifier with H and S turned off. This single-component keyer is more useful than you might think; it's a common technique to isolate a range of highlights, midtones, or shadows throughout the image to alter the color temperature selectively.

The Luma Keyer mode automatically disables the Hue and Saturation controls

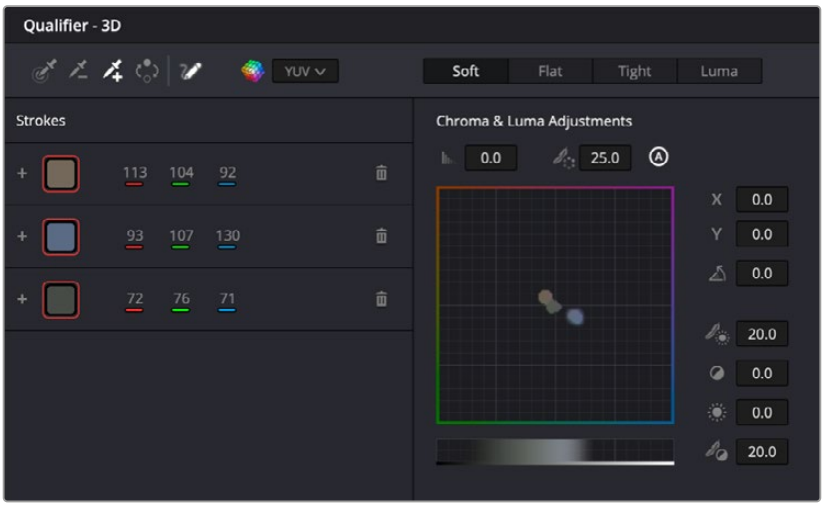
Also, keep in mind that the luma component is the sharpest keyable component when you're working with heavily compressed video. Keys that are noisy or chunky with HSL qualification may be sharper if you just use the Luma Qualifier, although you won't be able to be chromatically specific.

The Luma Qualifier has four parameters:

- **Lum Low/High:** Two parameters let you define the upper and lower range of the luma component being isolated.
- **Lum Low Soft/High Soft:** Two parameters let you define the upper and lower softness falling off outside the current range of luma.

3D Qualifier Controls

As discussed earlier in this chapter, the 3D Qualifier works much differently than the other qualifiers in DaVinci Resolve. In this mode, drawing lines over parts of the image you want to isolate adds samples to the Sample list, some of which add to the key (when you drag with the pointer) and some of which subtract from the key (when you Option-drag with the pointer). While this functionality is very simple to use, there are other controls that are available.



The 3D Qualifier mode

The 3D Stroke Pickers:

Picker: Chooses the initial color to qualify. Longer strokes will tend to give you a better key.

Picker -: Removes a color region from the qualifier; also available by holding down the Option key.

Picker +: Choses an additional color region to add to the initial qualifier.

Invert: Inverts the current key; qualified areas are then unqualified and vice versa.

Show Paths: A checkbox that lets you turn the visibility of the lines you're drawing to sample the image on and off. Turning lines off does not affect the key in any way.

Auto-B/W Highlight: With this checkbox enabled, the viewer automatically switches to Highlight B/W mode while drawing a line, to better show you the resulting key in real time. When the button is released the viewer will switch back to its original viewing mode.

Colorspace: A drop-down menu that lets you choose whether you're sampling colors in YUV colorspace, or HSL, HSP, or LAB colorspaces. YUV is the default, but if you find you're not getting satisfactory results, you can reset the Qualifier palette and switch to different ones to see if that works any better.

Strokes list: A list shows each line you drew as a sampled entry. A color patch at the left shows you the average color you sampled; clicking the color patch lets you temporarily turn any color sample off to evaluate its contribution to the overall key. A plus or minus icon shows you whether that patch is adding to or subtracting from the key. The average red, green, and blue color values are shown next, and a trash can icon at the right lets you delete any sample from the list.

The 3D Qualifier Modes:

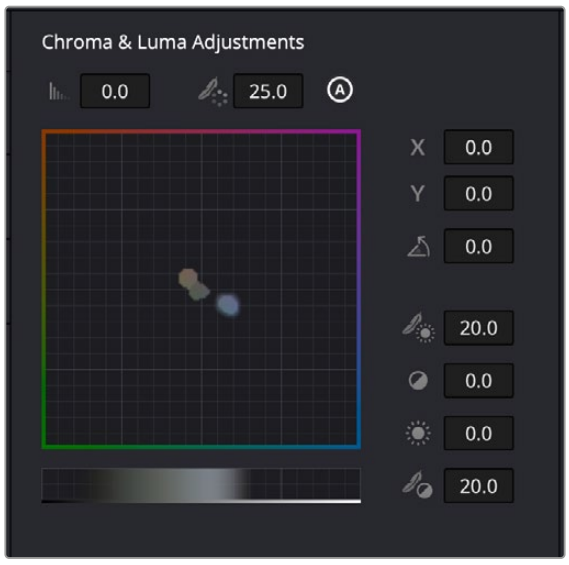
Soft: Provides a softer edge to the key that is more forgiving of Chroma and Luma adjustments. The more gentle drop-off is suitable for situations like subtle light changes across a face. Use the Shadow / Midtone / Highlight Matte Finesse Controls in conjunction with this mode to fine tune the result.

Flat: The default mode. Each color selected is 100% keyed, and adjustments are made for small color variations. This is the ideal mode for chroma keying a green or blue screen. Additionally, turning up the Pre-Filter setting in the Matte Finesse controls can make for a smoother, flatter key.

Tight: Only keys the exact color picked, and does not apply any softening based on color ranges. You chose that exact color, and only that exact color. Single pixel sharpness levels are expected. This can be used for difficult keying jobs, requiring adjusting the filter and softness manually in the Matte Finesse Controls.

Luma: Functions similar to the Tight setting but ignores all chroma data. This mode is used for black and white footage.

Despill: If you're using the 3D qualifier to pull a blue or green screen key to create transparency, this slider lets you adjust an automatic color correction that eliminates blue or green spill from the image, while retaining the image's original color.



The 3D Qualifier Chroma and Luma Adjustments showing the colors selected in the Strokes List.

The Chroma and Luma adjustment section is dominated by the Color Space box and the Brightness Range. The Color Space box is laid out roughly in the same manner as the Color Wheels, with primary colors laid out around its edge. The exact colors and layout is determined by the Color Space that you choose in the 3D Qualifier. The Brightness Range is represented as a bar underneath the Color Space, with left being black and right being white. Inside the Color Space and Brightness Range lie the individual colors that you chose with the pickers in the Strokes List. The tools around the periphery adjust the colors within the box in various ways, allowing you to visualize changes to the key.

The 3D Qualifier Chroma & Luma Adjustments:

Chroma Tolerance: Click and drag left and right to expand or contract the range of colors selected by the key.

Chroma Softness: Click and drag left and right to change the sensitivity to similar colors selected by the key. This determines whether the key is a hard cutoff or a soft selection of similar colors.

Adaptive Chroma Softness: Activating this icon allows the keyer to operate consistently in both highly saturated and desaturated regions of the image at the same time. The majority of the time you will want to leave this on. The exception is If you are having difficulty in manually adjusting chroma softness in Soft or Flat mode, then turning Adaptive Chroma Softness off will give you more range to work with. Adaptive Chroma Softness is automatically disabled in Tight and Luma modes, as it is contrary to the functionality of these modes.

X: Moves your selected color region within the color space, changing its chroma based on its horizontal position.

Y: Moves your selected color region within the color space, changing its chroma based on its vertical position.

Angle: Moves your selected color region within the color space, changing its chroma based on its rotation around the central origin point.

Low: Expands or contracts the dark areas of the key in the brightness range.

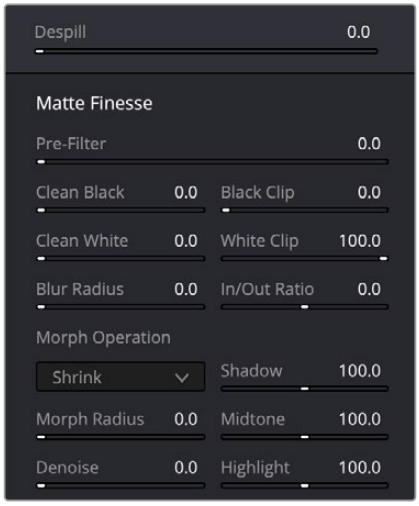
High: Expands or contracts the bright areas of the key in the brightness range.

Low Soft: Controls how well defined the low end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

High Soft: Controls how well defined the high end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

Matte Finesse Controls

After you've used the sample controls and qualifier parameters to create the most useful key for your purposes, you may find that it has problems that cannot be overcome easily by the available adjustments. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Qualifier controls and are adjustments that are made to the matte itself, so they may work well in some instances, and poorly in others, depending on what you're trying to do.



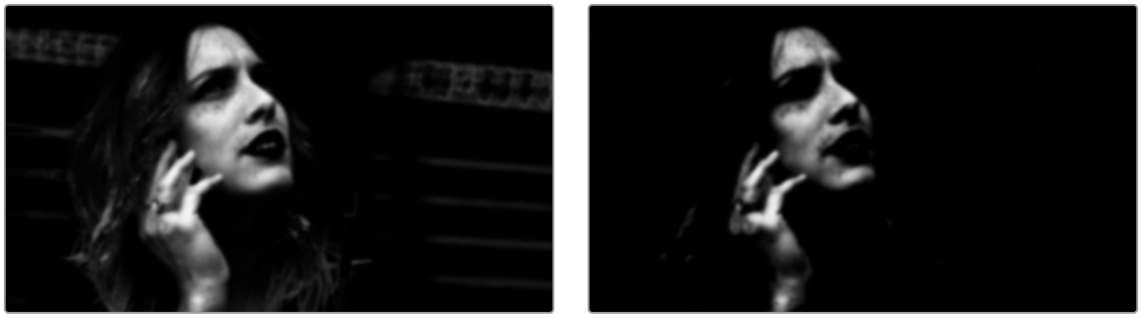
The Matte Finesse controls

Pre-FIlter

This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.

Clean Black

Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don't want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you "fill holes" in the background portion of a key and erode translucent edges.



Before/after raising Clean Black, viewing the high contrast matte

Black Clip

Raising Black Clip applies a "lift" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards black. The range is 0 to 100, with 0 being the default setting.

Before/after raising Black Clip

Clean White

Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that include areas of the image you're isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you "fill holes" in the foreground portion of a key and grow translucent edges.

Before/after raising Clean White, viewing the high contrast matte

White Clip

Lowering White Clip applies a "gain" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards white. The range is 0 to 100, with 100 being the default setting.

Before/after lowering White Clip

Blur Radius

In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you're keying, with the result being a visible "halo" around your subject depending on the adjustment you're making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.

TIP: If haloing is a problem, you can try adjusting the In/Out Ratio parameter, or you may want to consider using the Qualifier Softness parameters to feather the edges of the key, instead.

Using the Blur parameters to soften the edges of a key

In/Out Ratio

Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter.

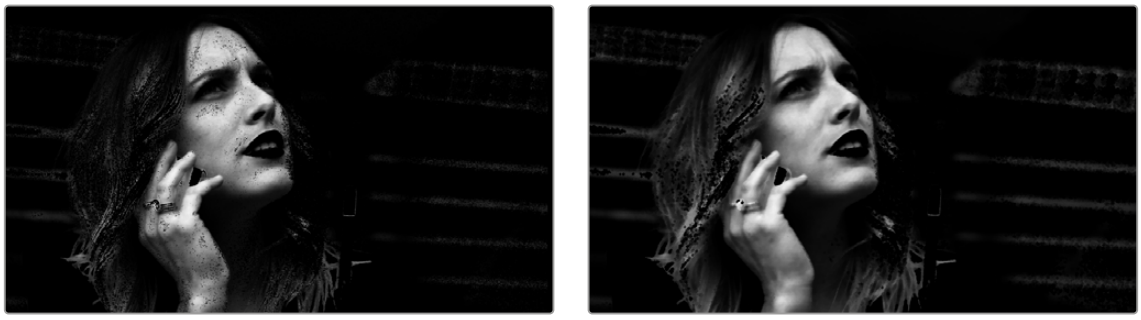
(Left) In/Out Ratio lowered so blurring ends at the edge of the matte and feathers inward,
(Right) In/Out Ratio raised so that blurring starts at the edge of the matte and feathers outward

However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.

(Left) In/Out Ratio controls lowered to expand holes in the matte, (Right) In/Out Ratio controls raised to fill in small black holes in the matte

Morph Operation

Lets you choose how you want to modify the alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.



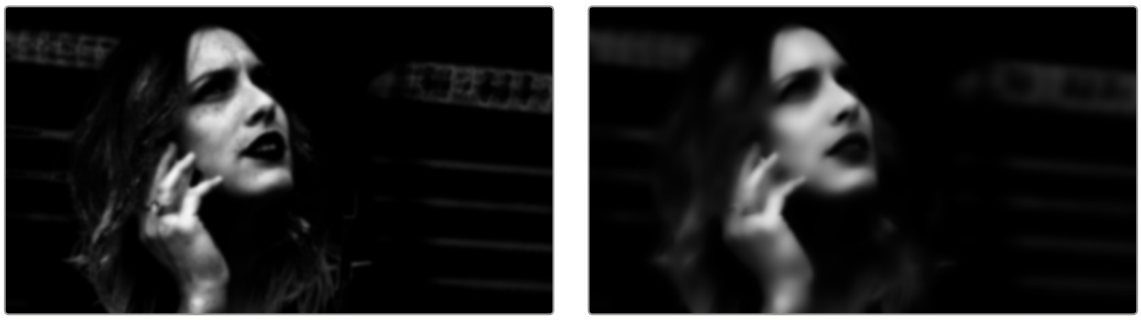
(Left) A matte with small holes in the face, (Right) Mode set to Shrink, Morph Radius set to 3; used to close holes in a matte

Morph Radius

Combined with Morph Operation, this slider adjusts how much to shrink, grow, open, or close the edge’s key.

Denoise

Denoise provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.



Before/after raising Denoise, viewing the high contrast matte

Shadow

Adjusts key strength based on the darker parts of the original image.

Midtone

Adjusts key strength based on the midtones of the original image.

Highlight

Adjusts key strength based on the brighter parts of the original image.

Post-Filter

Performs a final clean-up of the key, using the original image for reference, useful for bringing back some fine detail in sharp edges or hair.

The Many Ways to Invert a Key

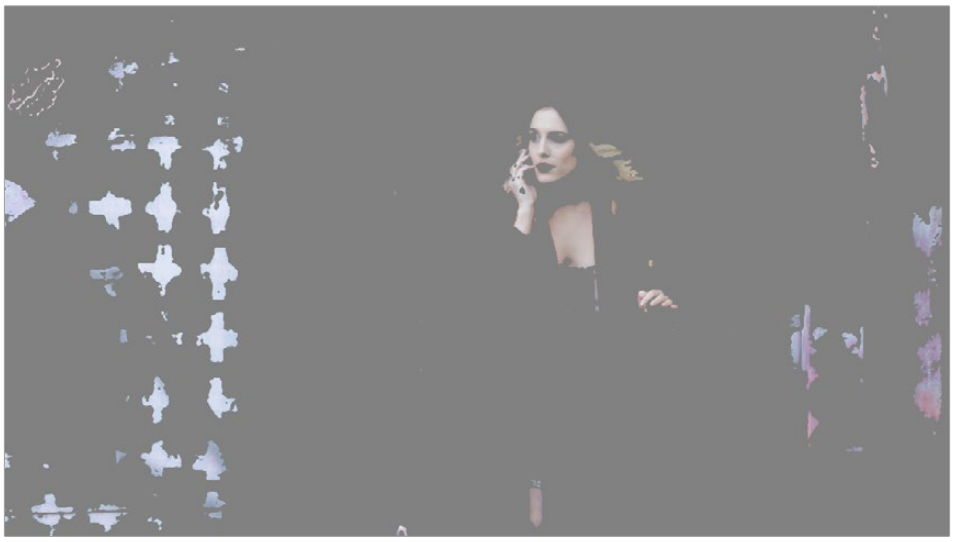
Sometimes, you'll need to isolate a subject or range of values in an image, and then make a change to everything else. One way to do this is to add an Outside node after the node in which you've created the key. This lets you make one set of adjustments to what you've keyed, and another set of adjustments to everything outside the key.

If you just need to make a simple adjustment, you can invert the key from within the Qualifier palette. However, there are three other ways to invert a key.

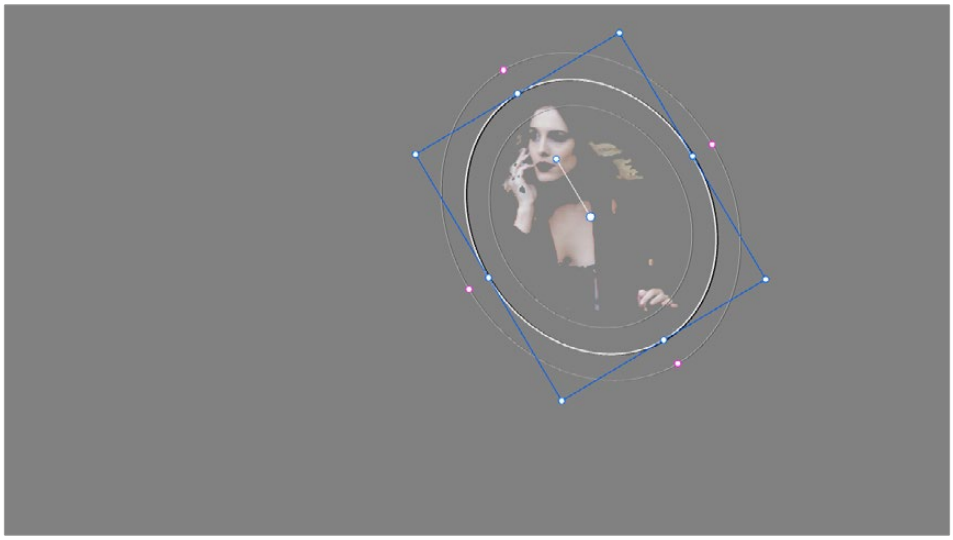
- **The Qualifier Invert button:** Clicking this control simply inverts the key being generated by all of the controls within the Qualifier palette.
- **Key Palette Qualifier Invert:** The Qualifier Invert control within the Key palette provides another control with which you can invert the key that's generated by the Qualifier palette.
- **Key Palette Output Invert:** The Output Invert control within the Key palette is notable because it inverts the sum of all keys applied within that node. For example, if you're using a Qualifier in conjunction with a Window, the two invert controls mentioned previously will only invert the Qualifier key; the Window key remains unaffected. However, using the Output Invert control inverts the overall combination of the Qualifier key and the Window, all together.

Combining Qualifiers and Windows

This is covered in more detail in a subsequent section, but if you create a key using one of the Qualifier modes, and you then add a Window, the final key that's output by that node is limited to the intersection of the Qualifier key and the Window. This makes it easy to use a Window to "garbage matte" out bits of a key that you don't want, that can't be eliminated by further adjustment of the Qualifier controls.



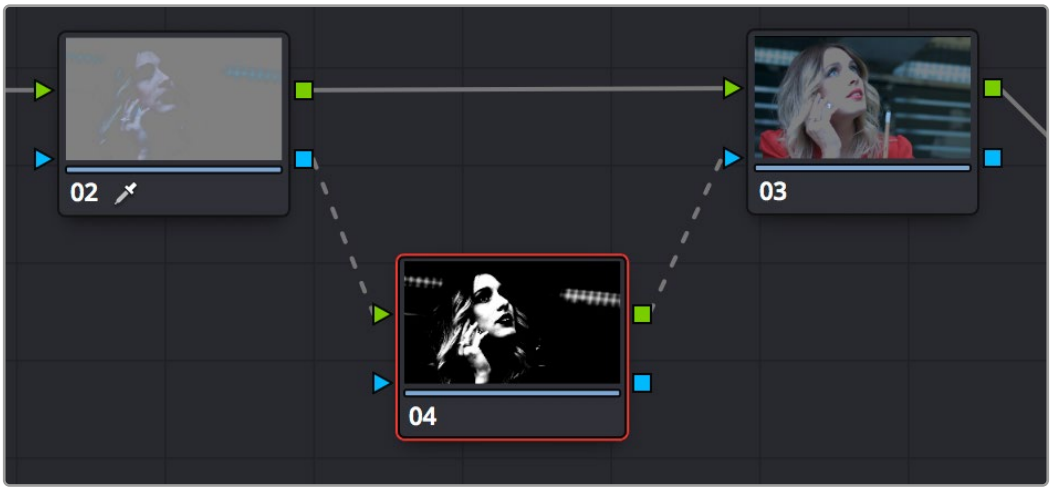
The woman's skin tone is too close to other elements in the scene.



A Circular Power Window is used to further isolate the woman being isolated.

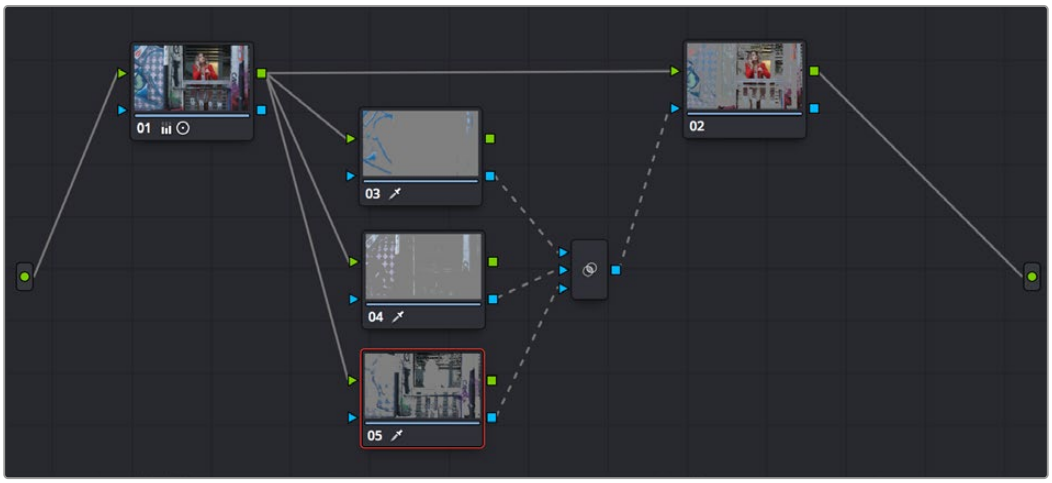
Manipulating Keys Using Additional Nodes

If you need to make more adjustments to a qualified key than the Matte Finesse controls will allow, you can use the Node Editor to feed the key output of one node to the RGB input of another, at which point you can use all of the second node's color adjustment controls to manipulate the grayscale image that constitutes that key, to improve it.



Connecting a key output to an RGB input, and then connecting the RGB output back to the next node's KEY input again

You can also use the Key Mixer node to combine multiple keys in several different ways, adding keys together, or subtracting them from one another, in order to create exactly the key you need.



Adding multiple keys together using a Key Mixer

For more information about these techniques, *see Chapter 144, "Combining Keys and Using Mattes."*

Chapter 136

Secondary Windows

Secondary correction describes isolating a specific part of the image, or a specific subject, using a key.

Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black).

Keys are generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte.

For more information on how to use external mattes, *see Chapter 144, "Combining Keys and Using Mattes."* This chapter shows you how to use Power Windows to create shapes with which you can isolate parts of the image in different ways in order to do these kinds of targeted corrections.

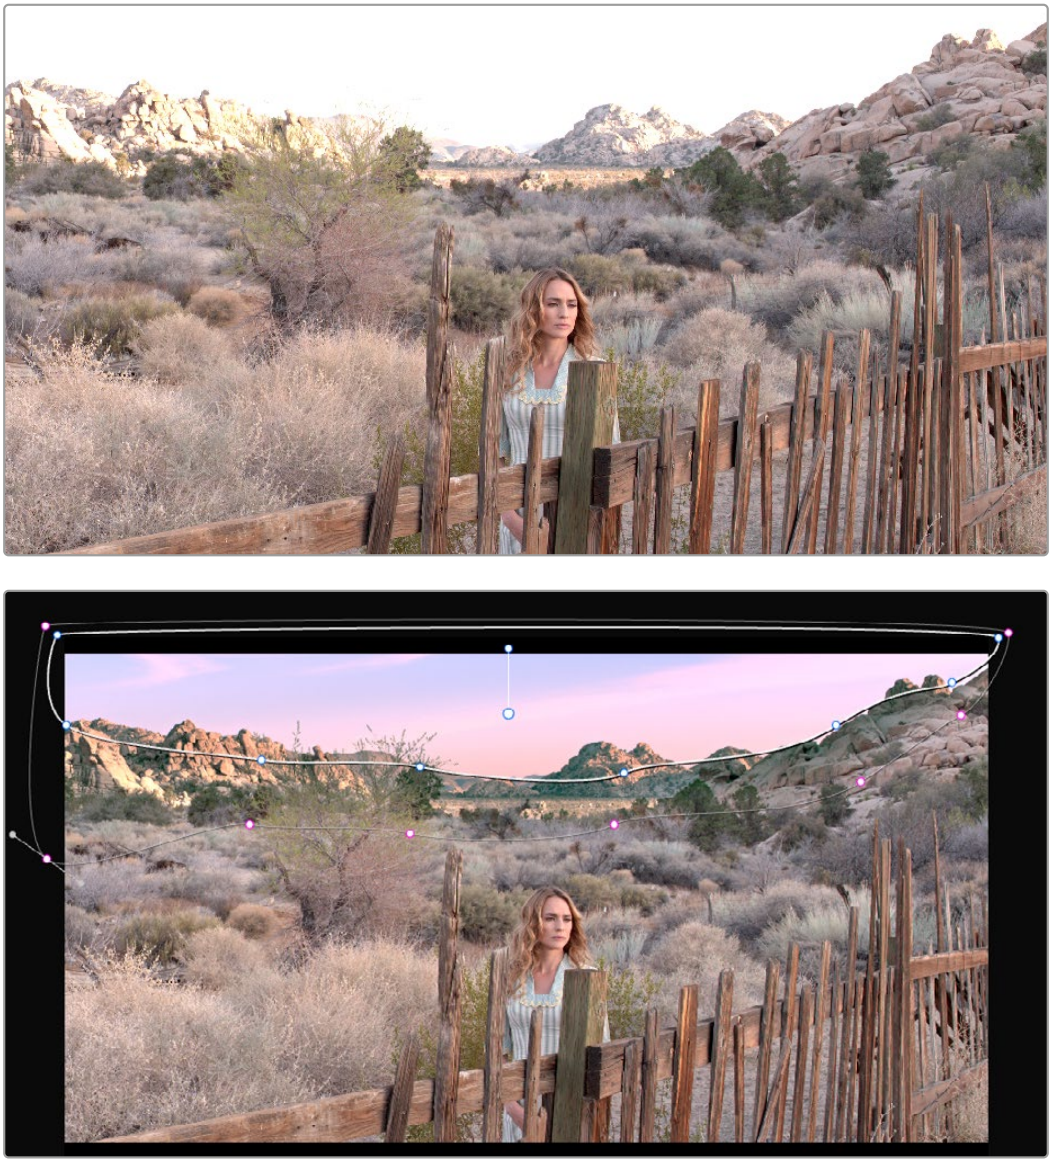
Power Windows

Power Windows are another way of making secondary correction, being essentially shapes you can use to isolate regions of the image. Different controls let you use oval, rectangular, polygonal, or custom curved shapes. Because you can isolate regions of the image by drawing, Power Windows produce exceptionally clean results, with edges that can be precisely positioned and feathered to achieve a variety of effects.

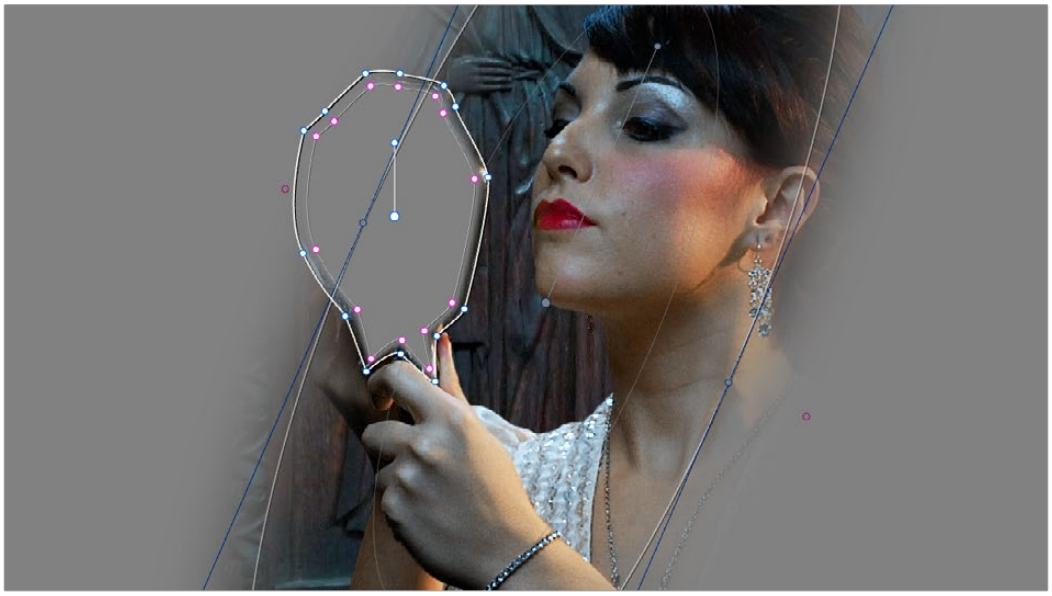


Before/after Curve Power Window isolates the sky area for a targeted correction.

Power Windows (also referred to as simply “windows”) are excellent when what you need to adjust can be encompassed within a clearly defined geometrical area. For example, the oval of a person’s face, the front of a car, or a wide expanse of sky are all good candidates for windowed adjustments. A drawback of windows can be that they must be animated to follow whatever subject they’re isolating. Fortunately, this is where DaVinci Resolve’s powerful tracker comes in, making it easy to track Power Windows quickly and accurately to follow along with the subject being isolated.

Circular Power Window to focus attention to the skin

DaVinci Resolve makes it easy to combine multiple Power Windows in different ways, to intersect with one another and create even more sophisticated shapes. For example, multiple windows can be added together, or one window can be used to cut out part of another window, which saves you from the need to make complicated keyframing operations to animate that window's shape.



Multiple windows combined to isolate and mask the image.

This section covers the use of Power Windows, how to create and modify them, as well as how to combine multiple windows, and combine windows and qualifiers to create highly specific isolations.

Adding Nodes with Windows

As with qualifiers, you must first add a node to a grade's node tree before you begin windowing a correction. This is because all of the windows within a particular node work together to limit that node's grade. As a reminder, any node can be changed from a primary operation that affects the entire image, to a more targeted secondary operation, simply by turning on a window, using a qualifier, or enabling an external matte.

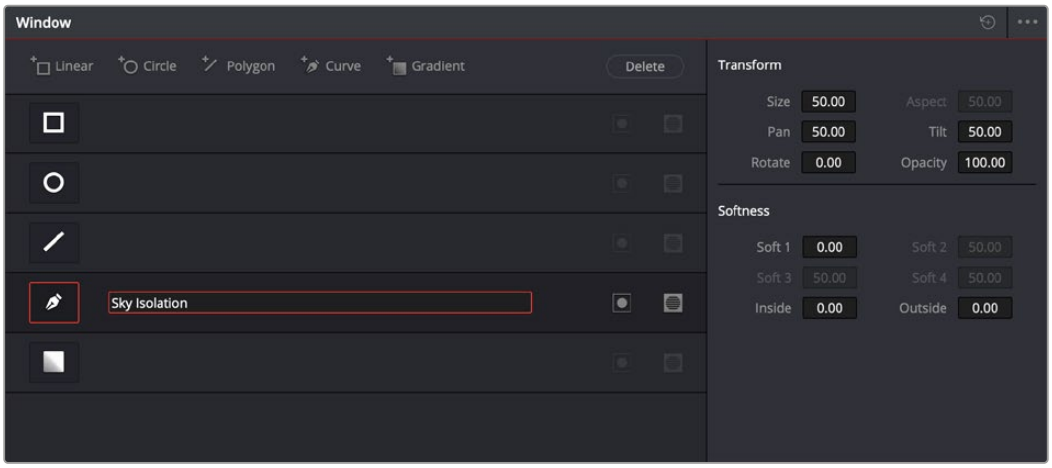
Serial nodes showing the window on Node 2

If you don't create a new node before creating a window, you'll discover you've inappropriately changed a primary correction into a secondary correction. If you create a new serial node, you'll then need to use the controls found within the Window palette to turn on a window to customize for your purposes. However, there are also a set of commands you can use to add serial nodes with a window already turned on, saving you a few clicks or button presses in the process.

To add a new node with a window already turned on:

Choose Color > Nodes > Add Serial Node + CPW (Option-C) to create a new serial node with a circular window.
Choose Color > Nodes > Add Serial Node + LPW (Option-Q) to create a new serial node with a linear window.
Choose Color > Nodes > Add Serial Node + PPW (Option-G) to create a new serial node with a polygonal window.
Choose Color > Nodes > Add Serial Node + PCW (Option-B) to create a new serial node with a Curve window.

When you add a node with a Power Window, the Window palette automatically opens up, ready for editing.



The Window palette

- **The Window palette is divided into three sets of controls:** the Window list, the Presets, and the Transform and Softness controls.

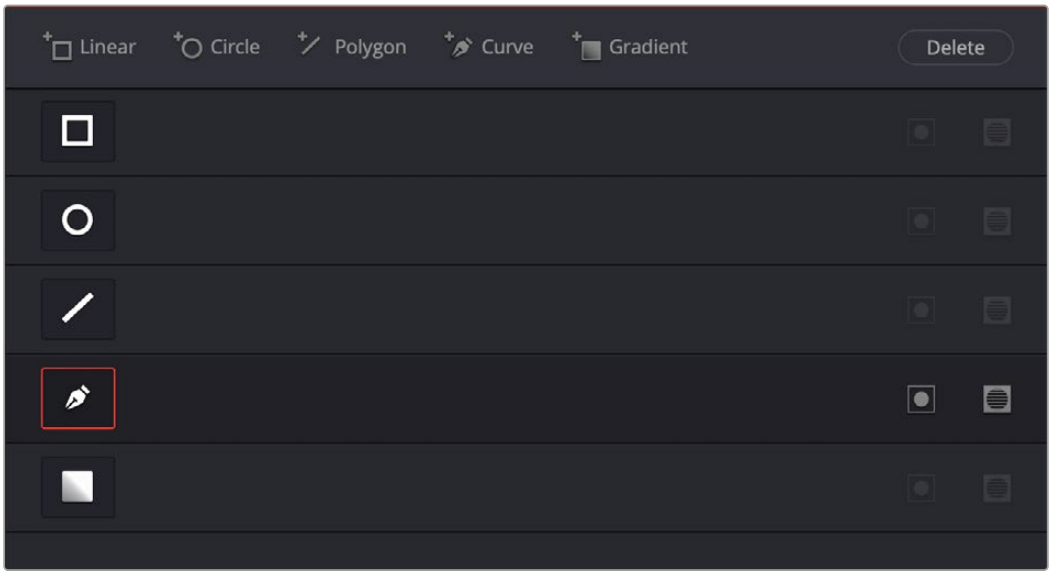
The Window Palette Interface

Once you've created a node with which to apply a Power Window correction, you need to open the Window palette if it hasn't been opened already.

To open the Window palette:

- Click the Window palette button.

The majority of the Window palette is occupied by the Window list, within which you can create as many windows as you need for the task at hand. There are five types of windows you can create, each of which has a different geometry. You can use these windows individually, or you can combine them to create even more complex shapes and interactions. The Window palette has four groups of controls that let you use these windows in different ways.



The Window palette with the Window list

- **Window list:** A row of buttons at the top of this list lets you add new windows, which you can then customize as necessary. Each window in the list exposes an On/Off button that shows the shape type, a Layer Name field (blank until you add some text) that you can use to identify what each window is for, an Invert button, and a Mask button that governs how that window interacts with the other windows that are currently enabled (adding to other windows by default, or subtracting from other windows in Mask mode).
- **Transform parameters:** Controls the overall size, aspect ratio, position, and rotation of the currently selected window.
- **Softness parameters:** Controls the edge softness of the currently selected window. Different window shapes have different softness options.
- **Option drop-down menu:** The Option drop-down menu has commands for creating and modifying custom window presets for easy recall later, resetting windows, deleting windows, saving and managing window presets, and copying and pasting track data.

Using buttons along the top of the Window palette, there are five types of windows you can create:

- **Linear:** A four-point shape that can be edited into any kind of rectangle or trapezoid you might need. In addition to the center and corner controls, you can also drag any of the four sides to change the shape.
- **Circular:** An oval that can be shaped, sized, and feathered to solve an amazing number of problems.
- **Polygonal:** A four-point shape that can be expanded with additional control points to create complex sharp-cornered polygonal shapes.
- **Curve:** A Bezier drawing tool that you can use to create any kind of shape, curved, polygonal, or mixed, that you require.
- **Gradient:** A simple two-handled control for dividing the screen into two halves, with options for the center, angle, and feathering of the shape. Good for fast sky adjustments.

Managing Windows

To manipulate a window, first you need to create the type of window you want to use, or if you've got a group of windows created already, you need to select the window you want to work on.

Methods of creating and selecting windows:

- **To create a new window:** Click the Shape icon button or click the Create Window button (at the top of the Window list) that corresponds to the window you want to create.
- **To select a window using the onscreen controls:** Click anywhere within a window to select it in the Viewer.
- **To select a window from the Window list:** Click the Shape icon button corresponding to the window you want to select.

To delete a window you no longer want:

- Select a window, then click the Delete button.

To reset a window:

- **To reset one window to its default shape:** Select a window, then choose Reset Selected Window from the Option drop-down.

Showing and Hiding Onscreen Window Controls

When you open the Window palette, the Viewer goes into Power Window mode. Enabling a window makes that window's onscreen controls appear within the Viewer, and are mirrored to video out so you can see the window controls on your external display. If you like, you can change how and where the onscreen controls appear.

To choose whether onscreen controls are mirrored to video out, or disabled, do one of the following:

Choose an option from the Window Outline submenu in the Viewer's option menu.
There are three options:

- **Off:** Hides the window outline on both the external display and the Viewer.
- **On:** The default, shows the window outline on both the external display and the Viewer.
- **Only UI:** Hides the window outline on your external display, but leaves it in the Viewer.

> Press Option-H to toggle among all three of the above modes.

This command is a three-way toggle. The first use of this command hides the window outline on your external display, but leaves it in the Viewer. The second use of this command hides the window outline on both the external display and Viewer. The third use of this command shows the window outline on both the external display and Viewer.

TIP: If you leave the onscreen controls visible in the Viewer, you may find that as you work you want to temporarily hide or show the onscreen controls in the Viewer so you can get an uncluttered look at the image you're adjusting. You can quickly toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).

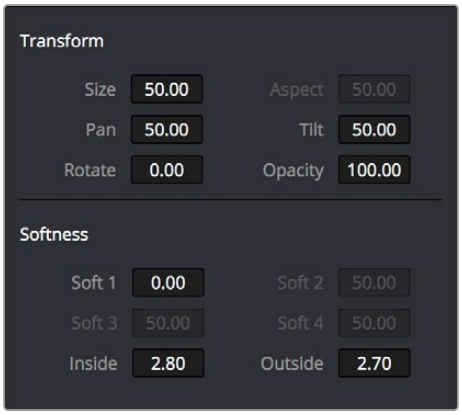
Using the High-Visibility Power Window Outline Option

Ordinarily, Power Window outlines are white (for the center shape) and gray (for the softness shapes). However, sometimes this color scheme can be difficult to see, so the Color panel of the User Preferences has an option in the General Settings section called "High visibility Power Window outlines." Turning this on sets Power Window outlines to be drawn as green (for the center shape) and yellow (for the softness shapes), to make these windows easier to see in certain circumstances.

(Left) Default window outlines, (Right) High Visibility window outlines enabled in the Color panel of the User Preferences

Window Transform Controls

Windows have transform parameters that are similar to those found in the Sizing palette. These parameters let you alter the window, affecting all of its control points together.

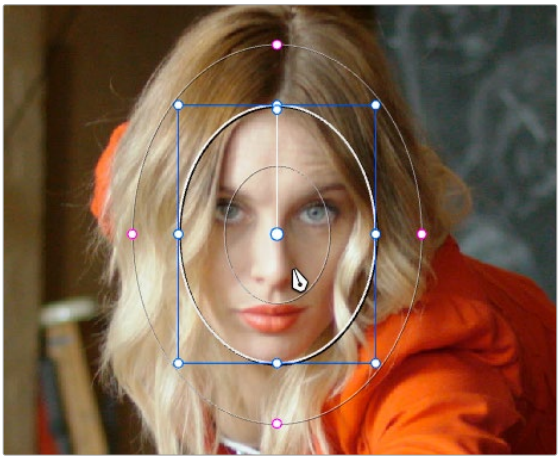


Window transform controls

- **Size:** Scales the entire window up or down. 50.00 is the default size.
- **Aspect:** Alters the aspect ratio of the window. 50.00 is the default value, larger values make the window wider, and smaller values make the window taller.
- **Pan:** Repositions the window along the X axis. 50.00 is the default position, larger values move the window to the right, smaller values move the window to the left.
- **Tilt:** Repositions the window along the Y axis. 50.00 is the default position, larger values move the window up, smaller values move the window down.
- **Rotate:** The default value is 0. Increasing this parameter rotates the shape clockwise, decreasing this parameter rotates the shape counterclockwise.
- **Opacity:** Lets you vary the transparency of an individual window's contribution to a node's key.
- **Convergence:** When "Apply stereoscopic convergence to windows and effects" is enabled in the General Options of the Project Settings, this additional Transform parameter appears that lets you create properly aligned convergence for a window placed onto a stereoscopic 3D clip.

For more information about working with Stereoscopic 3D projects, *see Chapter 15, "Stereoscopic Workflows."*

The transform parameters also correspond to onscreen controls found in the Viewer, which can be manipulated directly using the pointer.



Manipulating the window position on the Viewer

While many of the onscreen controls correspond to parameters within the Window palette, some onscreen controls, such as the control points that govern reshaping linear, polygonal, and Curve windows, are only adjustable via the pointer.

Onscreen controls for window transforms:

- **To select any window:** Click on one of an arrangement of many windows to select it, making that window's controls active.
- **To reposition any window:** Drag anywhere within the window's onscreen control. Window position corresponds to the Window palette's Pan and Tilt parameters. For a gradient window, drag the center control point.
- **To resize a circular window while locking its aspect ratio:** Drag one of the four blue corner points out to enlarge, or inwards to shrink. This corresponds to the Window palette's Size parameter.

- **To squish or stretch a circular window, altering its aspect ratio:** Drag one of the blue top, bottom, left, or right control points. These adjustments correspond to the Window palette's Aspect parameter.
- **To rotate a window:** Drag the top inner white rotate handle, in the middle of the window. For a gradient, drag the bottom arrow handle.
- **To alter window softness:** Drag any one of the magenta softness handles. Different window shapes have different sets of handles, which correspond to the Softness parameters.
- **To reshape a linear window:** Drag any of the white corner handles to corner pin the window, or drag one of the white top, bottom, or side handles to move an entire side segment of the window around.
- **To reshape a polygonal window:** Turning on a polygonal window reveals a simple white rectangle with four corner control points. Click anywhere on the surface of the rectangle to add additional control points with which to reshape the polygon, and drag any control point to alter its shape. Polygonal windows are limited to a maximum of 128 control points.
- **To change the size and aspect of a curve:** Shift-drag a bounding box around the control points you want to transform, and then adjust the corners of the box to resize the points while maintaining the aspect ratio of the shape, or adjust the top, bottom, left, or right points to squish or stretch the shape.
- **To remove control points from polygonal or Curve windows:** Middle-click the control point you want to remove.

NOTE: Removing a control point from a polygonal window that's already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

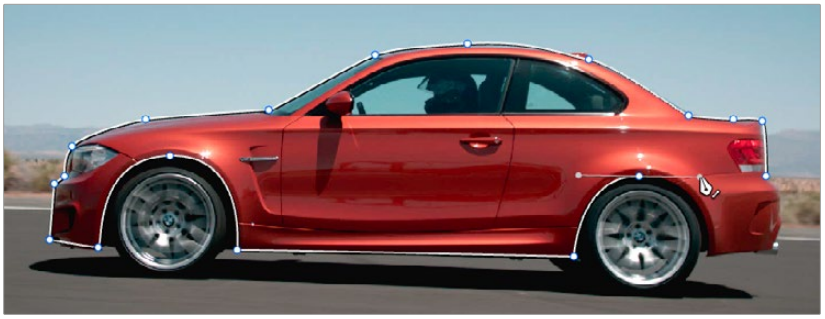
Window Softness

Each type of window has different Softness parameters, depending on how adjustable that window is.

- **Circular:** A single parameter, Soft 1, lets you adjust the uniform softness of the oval's edge.
- **Linear:** Four parameters, Soft 1–4, let you adjust the softness of each of the four sides of the linear window independently. Magenta softness control points on the top, bottom, left, and right let you adjust the softness of each side of the linear shape independently.
- **Polygon:** Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a polygonal window. There are no onscreen softness control points.
- **Curve:** Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a curve. Using the onscreen controls, you can adjust the magenta inside and outside softness control points independently, creating any softness shape you need.
- **Gradient:** A single parameter, Soft 1, lets you adjust the uniform softness of the gradient window's edge.

Drawing Curves

The Curve window is the only window that doesn't display any onscreen controls when it's first turned on. Instead, you must click within the Viewer to add control points, drawing your own custom shape to isolate whatever region you want.



Curve window to isolate a car

TIP: Turning on the Viewer's full-screen mode can make it easier to draw detailed shapes. You can also zoom into and out of the Viewer while you're drawing, using either the scroll wheel of a mouse or by pressing Command-Plus or Command-Minus.

To draw a curve:

1. Turn on the Curve window style control.
2. Click anywhere in the Viewer to start adding control points and drawing the shape you need.
3. Click and drag to add and shape Bezier curves, or just click and release to add a hard angle.
4. To finish drawing and close the shape, click the first control point you created to create a corner, or click and drag on the first control point you created to create a Bezier curve.

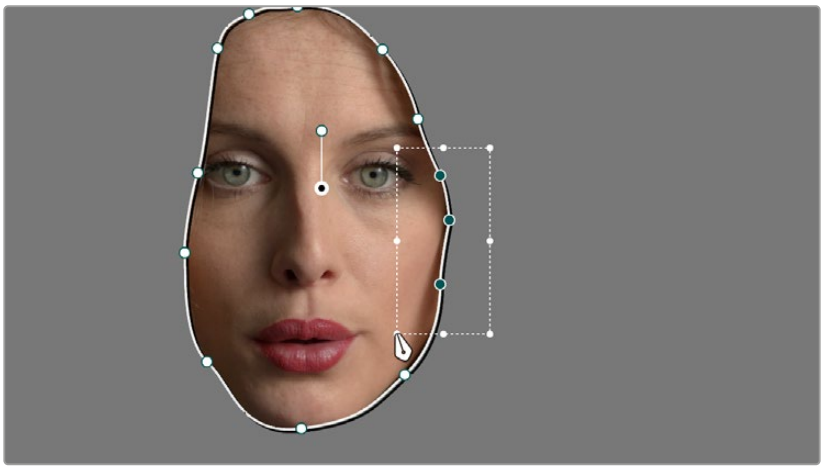
   Once you've drawn a curve, there are many ways of manipulating it.

Simple methods of modifying a curve:

- **To add points:** Click anywhere on a curve to add control points.
- **To reshape a curve:** Drag any control point to a new location. You can drag control points even while you're drawing a new curve, selecting previously drawn points to move them, to adjust their spline handles, or to delete previously added points, without the need to finish the window first.
- **To move a curve:** Drag anywhere within or just outside a curve to move it.
- **To symmetrically alter a Bezier curve:** Drag any Bezier handle. The opposite handle automatically moves in the other direction.
- **To asymmetrically alter a Bezier curve:** Option-drag any Bezier handle. The opposite handle stays in place while you drag the current handle. Once you've created an asymmetric pair of Bezier handles, they move together as one if you simply drag a handle. You need to Option-drag to change the angle.
- **To change a curve into a corner:** Option-double-click any Bezier curve control point to change it to a sharp-angled corner point.
- **To change a corner into a curve:** Option-click any corner point and drag to pull out a Bezier handle, changing it to a curve.
- **To remove points:** Middle-click the control point you want to remove.

NOTE: Removing a control point from a polygonal window that's already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

You can also Shift-drag a bounding box to select multiple control points on a curve to move, delete, or transform them all at once.



You can Shift-drag a bounding box over multiple control points to manipulate them all at once.

To select multiple control points on a curve:

1. Hold the Shift key down and drag a bounding box around the control points you want to manipulate or delete. All included control points will become highlighted.
2. Do one of the following:
   - **To move the control points:** Drag anywhere within the bounding box.
   - **To transform the control points:** Drag one of the outer corners to resize all control points symmetrically, drag the top, bottom, or side handles to squish or stretch the control points relative to one another, or move the pointer to one of the corners until the rotate cursor appears, and then drag to rotate the control points.
   - **To delete the control points:** Press the Backspace key.
3. When you're finished, press the Escape key to deselect the control points.

Converting Linear, Circular, and Polygon Windows into Bezier Curves

If you start out isolating a subject using one of the simple Linear, Circular, or Polygon shape windows and you realize that you need a more complex shape to accomplish the task at hand, you can easily convert them to a more complex Bezier curve by choosing Convert to Bezier from the Window palette Option menu.

Before and after converting a circular window to a Bezier curve and adjusting the result, before adding softness to the edge

Once you've converted a simple shape to a Bezier window, you can add control points and manipulate the shape in any way you need to make it better conform to the subject, just as you would with any curve.

Resetting the Window Palette

The entire Window palette can be reset using the Option menu's Reset command.

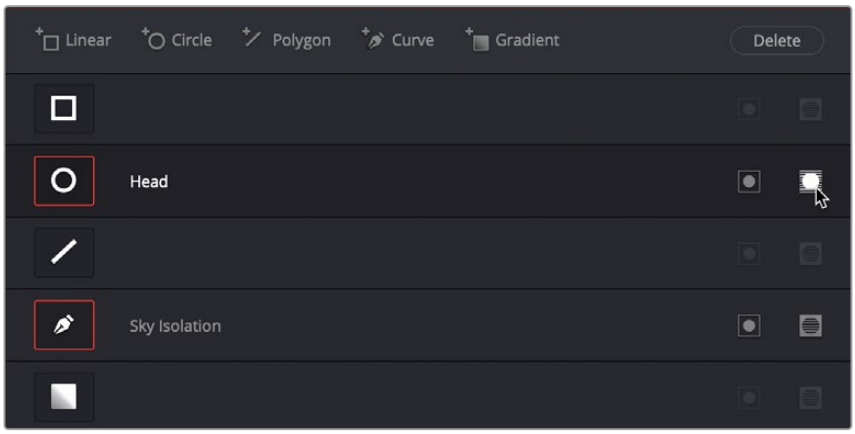
Combining Power Windows with the Mask Control

Adding multiple windows to a single node is an easy way to create composite keys. When combining windows, the Mask control defines whether one window adds to another window, or subtracts from that window.

In the following example, Circular and Curve windows have both been created, and each window's Mask control is also turned on (by default), resulting in both masks being added together so that the sunset look correction affects both the sky and the woman's face.

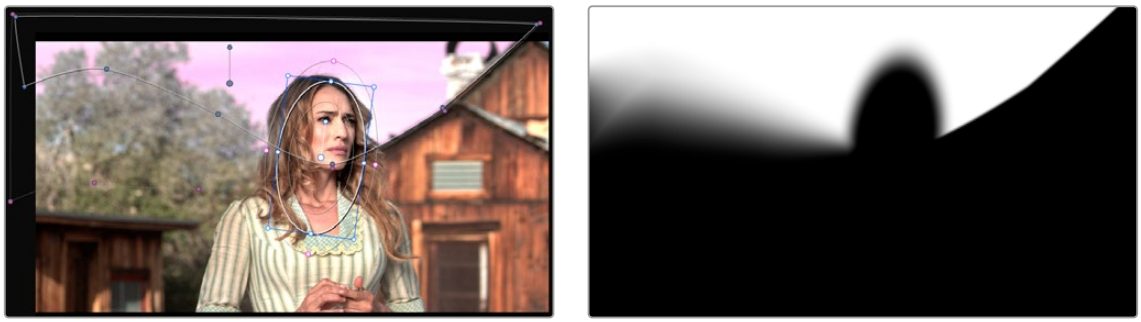
The two images show the combination of the key mattes.

By turning the Mask control of the circular window off, the circular window is subtracted from the curve.



Turning off the Mask control of the circular window

Now, the woman's face is being protected from the aggressive sky treatment.



The two images show the result of subtracting the circular window

Since windows can be individually tracked and keyframed, you can quickly set up complex interactions of windows to solve common problems you'll encounter. For example, when you're tracking a window to follow a moving subject that moves behind something in the frame, you can use a second window with Mask turned off to cover the object in front. Now, when the tracked window intersects the subtractive window, the correction will disappear along with the subject.

You can also use the Mask control to create more complex shapes than you can with a single window.

Mattes and mask used together to make complex shapes

Furthermore, once you reach the limits of what shapes you can create using the four available windows, you can combine multiple nodes containing multiple shapes and qualifiers using the Key Mixer.

Copying and Pasting Windows

If there's a particular window you've created that you want to either duplicate within the current node, or apply to another node, you can copy and paste an individual window's shape from one item in the Window list to another.

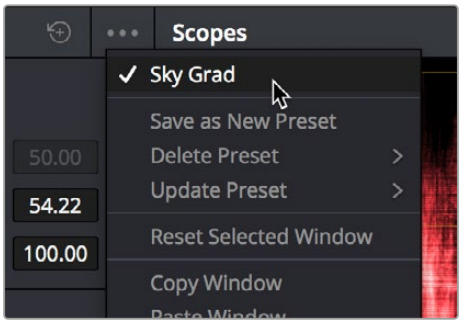
Methods of copying and pasting windows:

- **To copy a window:** Click any enabled window in the Window list, then click the Window palette option menu and choose Copy Window.
- **To duplicate a window:** After copying a window, create another window of the same type that you copied, and then click the Window palette option menu and choose Paste Window.
- **To paste a window to another node:** Double-click or otherwise select another node, open the Window palette, choose the same type of window that you copied in the Window list, and then click the Window palette option menu and choose Paste Window.
- **To paste a window to the same node:** Click any enabled window in the Window list, then click the Window palette option menu and choose Copy Window, then click Paste Append Window in the Window Option menu.

Saving Window Presets

If you find there's a particular window shape or combination of windows that you use frequently, you can save one or more windows as a preset for easy recall whenever needed. For example, if you're working on a documentary within which you find you need to do a lot of face brightening, you can create preset face ovals for close-up, medium, and wide shots, to save you from having to customize a stock circular window for every single new shot. You can also save groups of windows together as a single preset, in order to reuse complicated multi-window shapes.

Window presets are available from a group of Presets controls in the option menu in the upper right-hand corner of the Window palette.



Controls for saving, applying, and deleting window presets

Methods of working with Power Window presets:

- **To save a window preset:** Once you've created one or more windows you want to save, click the Save as New Preset option in the Window palette's option menu. Type a name into the resulting dialog, and click OK. That preset is now available in the Preset section of the option menu.
- **To recall a window preset:** Click to open the Window palette's option menu, and choose a preset from the list. Loaded window presets overwrite whatever other windows were set up in that node.

- **To update an already saved preset:** Recall a preset, change the resulting window(s), then click to open the Window palette's option menu. Select Update Preset, then select the preset name. This will overwrite the selected preset with the altered window arrangement.
- **To delete a window preset:** Click to open the Window palette's option menu, and choose Delete Preset, then choose a preset from the list. Make sure you chose the correct preset name; there is no warning before the deletion, and you cannot undo the deletion once it's done.

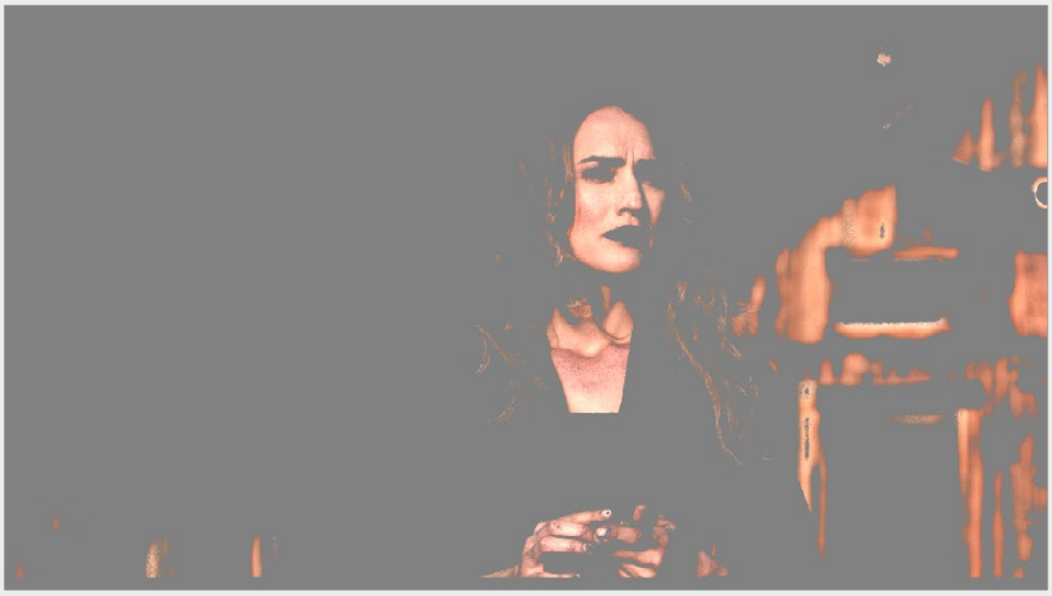
Once recalled, windows created by presets can be modified and tracked just like any other window.

Using Windows and Qualifiers Together

Another use of windows is to act as a "garbage matte" when used together with a qualifier. By default, when you use a window and qualifier together, a key is only output where both the window and qualifier intersect. This makes it easy to exclude unwanted parts of a key that are too difficult to eliminate by further refinement of the qualifier controls.

For example, the following qualification is intended to isolate the woman's face, but some of the similarly colored wood and sky in the background is also included.

Instead of driving yourself crazy trying to eliminate the unwanted parts of the key by modifying the current qualification, which is doing a great job of isolating the skin tones, you could instead use a window to isolate her face, excluding everything outside the window, and simplifying your job considerably.



A qualified image with highlight on

If she moves, then you can simply track the window to follow. For simple tracking *see Chapter 138, "Motion Tracking Windows."*

Now with additional Power Window isolation

Furthermore, you can use the window's Invert control to do the reverse, excluding all qualified portions of the key inside the window, and including all qualified portions of the key outside the window.

If you need to build more complex qualifier/window combinations than this, you can add more windows, or you can use multiple qualifiers and windows with the Key Mixer node, *see Chapter 144, "Combining Keys and Using Mattes."*

Chapter 137

Magic Mask

The Magic Mask palette uses the DaVinci Neural Engine, guided by the user via a stroke-based interface, to automatically create detailed masks with which to isolate objects or humans, either whole or in part, to which you want to make secondary adjustments in DaVinci Resolve.

This chapter describes how to guide these powerful features using the stroke and tracking controls found within this palette.

Magic Mask (Studio Version Only)

The Magic Mask palette uses the DaVinci Neural Engine to automagically create a mask to isolate one or more people or object in the frame, guided by user-applied paint strokes to identify the subject for isolation. Masks can be generated for either an entire object, person, or for specific features of that person (their face, hair, arms, shoes, etc.). The following images show these two kinds of masks with Highlight enabled in the Viewer. A red onionskin overlay lets you see what Magic Mask is isolating.

(Left) Using Magic Mask to isolate an entire person, (Right) Using Magic Mask to isolate someone's face

Once the Magic Mask palette has generated a mask, Matte Finesse controls let you adjust the mask's size and feathering. This lets you deal with difficult edges that might tip your hand depending on the kind of adjustment you're trying to make.

While the masks generated by Magic Mask can often be good enough to use directly for making high quality isolated adjustments, it won't always give perfect results. Keep in mind that Magic Mask is as much for the fast creation of detailed garbage masks as it is for doing direct isolation.

In these cases, the Matte Finesse controls let you make the resulting mask softer and looser as necessary to clear the edge of a difficult subject you're isolating with the help of another mask generation technique, such as a Qualifier key or window. When you use the Magic Mask palette within the same node in which you're also creating a key in the Secondary palette, or a window in the Window palette, the key or window and Magic Mask are combined to output a boolean intersection. This means the isolation is limited to areas where both kinds of masks overlap one another.

(Left) Using Magic Mask to create a mask, (Right) Combining the Magic Mask with a circular window, the resulting mask is an intersection of the two

Objects can also be isolated by Magic Mask, allowing you to create complicated masks of complex shapes that may be difficult to isolate with other tools. For example, using the Magic Mask in Object mode to modify only the wood grain section of this guitar.

(Left) Multiple strokes in Object mode isolating the wood grain of the guitar, while ignoring the musician's arm, (Right) The finished shot, with a warmer wood grain

If you're isolating specific features of a person, you can also mix and match what you're isolating to create exactly the type of mask you require. For example, you might isolate the face, along with exposed skin on the torso, arms, and legs, to create a mask for creating an overall skin tone adjustment that doesn't include the subject's hair or clothes.

(Left) Using Magic Mask to isolate a face, (Right) Using Magic Mask to isolate all exposed skin

As described earlier, this whole process is guided by strokes you draw to identify the subject. In a typical workflow, you'll draw short positive strokes (colored blue) over the person or feature you want to isolate. Then, if necessary, you can also paint short subtractive strokes (colored red) over parts of the image that are not the person or feature you're isolating, to correct any problems you see in the generated mask.

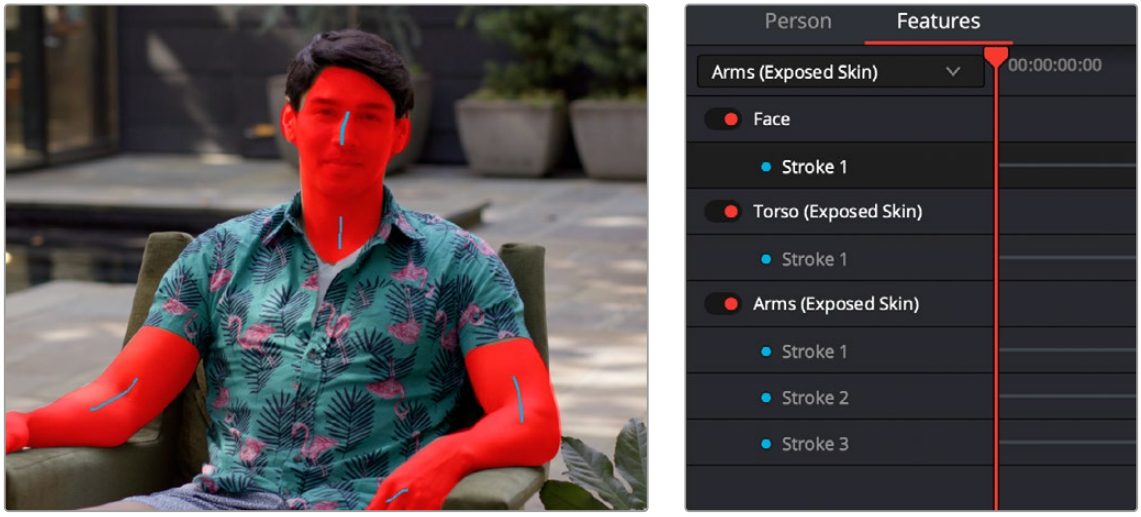
Blue strokes identify a person or feature to isolate, while red strokes identify things that shouldn't be included in the mask.

Ideally, both positive and subtractive guidance strokes should be relatively short, and centered on the part of the person or object you're trying to add to the mask. Stroke position is usually more important than stroke length, and in fact if you don't like the result you're getting in the mask with a particular stroke you've drawn, you can drag it to another position without redrawing it; strokes are live and can be selected using the pointer to move or delete them.

Selecting a stroke with the pointer;
selected strokes become highlighted.

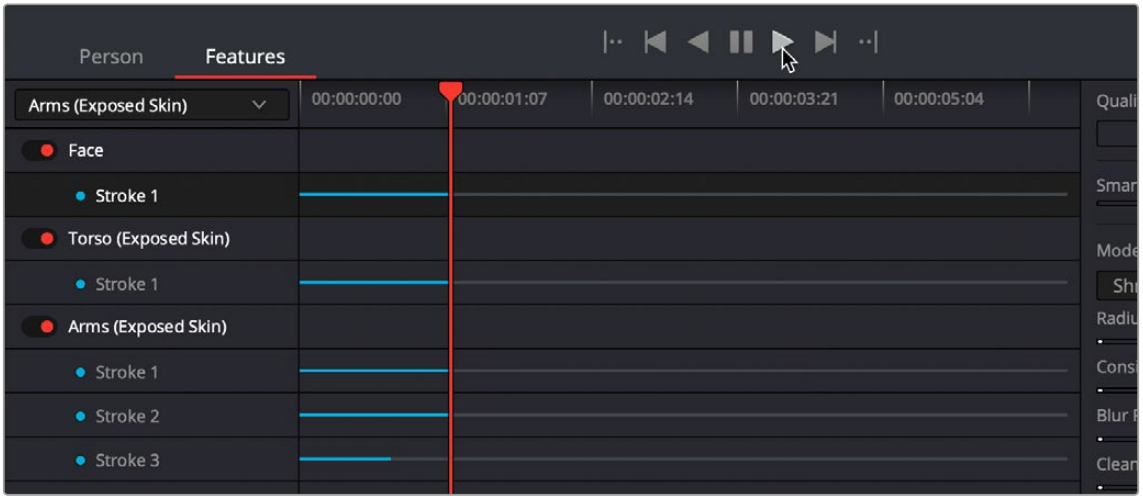
Very long paint strokes aren't usually that useful, and can be counterproductive later on when you're trying to track strokes to follow motion in the clip. This is particularly true if a stroke needs to follow something that's changing shape as it moves, like an arm. Furthermore, while you can make as many strokes as you like, fewer strokes work better than many strokes, and as a general rule you shouldn't use more than five strokes to isolate a particular person or feature (nor should you need to).

As you work, each stroke shows up in the Stroke list, which lets you select, enable/disable, delete, and otherwise manage the different strokes you create to guide automatic mask generation.



(Left) Multiple strokes in Features mode isolating exposed skin,
(Right) The Stroke list keeps track of all strokes you've made.

But what about camera and/or subject motion, you ask? After you've painted one or more strokes to guide the analysis, you can motion track these strokes to follow the subject throughout that shot using the stroke tracking controls within this palette. If you've made multiple strokes, they're all tracked at once, and each stroke automatically follows along with whatever image details immediately surround that stroke, so there's no setup necessary. You simply draw one or more strokes, then click the track forward or backward button. When you track a stroke, the tracking bar for that stroke in the Stroke list shows you which frames have been tracked (tracked frames are blue).



Controls let you track all mask analysis strokes forward and backward through the shot.

Once you've added the strokes that are necessary to isolate the subject, and you've motion tracked them to follow along with the motion of the shot, a mask is automatically generated live for each frame of the shot. This is important to know because any change you make, adding or removing strokes or moving them manually, will alter the resulting mask on the fly.

What Magic Mask Is Good For, and What It's Not

Keep in mind that the Magic Mask tool does not specialize in soft translucent mask edges, such as those created by the HSL, Luma, or 3D Keyers (when they're used carefully). On the other hand, it excels at creating form-fitting masks that isolate human features in situations where a typical keyer does poorly. For example, Magic Mask can isolate exposed skin in shots where that person is standing in front of a background with wood, stone, or soil that inhabits the same ranges of color as that person. It can isolate beige clothes against a beige background. It can even isolate a person within a black and white clip.

Once you've drawn one or more strokes to isolate a mask, a variety of controls let you adjust the resulting mask to better fit the subject, if necessary. Depending on the adjustment you're making to the subject at hand, you may find that the keys generated using Magic Mask are sufficient to convincingly isolate the person you're grading, particularly if you're working in Better mode.

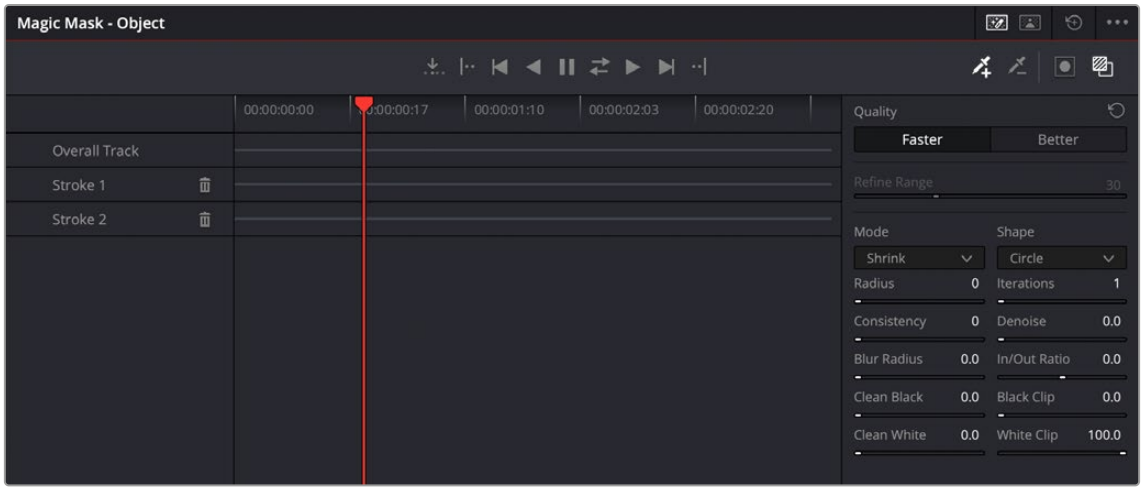
However, real world projects pose plenty of unexpected challenges. Keep in mind that, depending on what you're trying to do, the resulting automated mask isn't always going to be perfect enough to replace precise rotoscoping for intensive secondary color adjustments. However, it's been designed to easily create tight-fitting garbage masks to use in conjunction with secondary keys or windows, with which to exclude the background around a difficult-to-isolate subject.

If you're using Magic Mask to create a garbage mask, keep in mind that the Faster mode has been optimized to create looser masks more quickly for situations where you'll be using it in conjunction with a keyer or window to isolate a specific area for special grading.

TIP: The Magic Mask palette can even isolate people in photos and paintings. However, figurative representations must have a minimal level of shadow rendering and anatomical detail for a figure or feature to be recognized. For this reason, cartoony or abstract representations won't isolate very well.

The Magic Mask Interface

The Magic Mask palette is divided into three sets of controls: the Toolbar, the Stroke list, and the Mask Finesse panel. When you first open the Magic Mask palette, it's empty, and you're told to draw a stroke in the Viewer to create a mask.



The controls of the Magic Mask palette in Object mode

Magic Mask Toolbar

A toolbar at the top contains most of the interactive controls of the Magic Mask palette.

- **Object Mode:** Selecting this icon puts the Magic Mask tool into Object mode for isolating subjects that are not people.
- **Person Mode:** Selecting this icon puts the Magic Mask tool into Person mode for isolating people and parts of people. A tab control at the left lets you choose the type of mask you want created. There are two choices:

  Person: For creating a mask to isolate as much of a person is visible, given the framing of the shot.

  Features: For creating a mask isolating just someone's face, or hair, or arms, for example. In Features mode, you can also combine multiple specific features into a single mask.

- **Tracking Controls:** The following controls let you track all available strokes to follow camera or subject motion in the frame. From left to right, these include:

  Go To Reference Frame: Moves the playhead to the frame on which you initially drew the strokes.

  Go To First Frame of Tracked Area: Moves the playhead to the first tracked frame of a range of tracked frames, in preparation for tracking backwards if there are untracked frames at the beginning of the clip.

  Track One Frame Backwards: Tracks one frame backwards and stops. Useful if you're tracking frame by frame to watch the progress of a particularly complicated bit of motion. If something goes wrong, you can back up to the last frame where the stroke was able to properly track the subject, and drag the stroke to a better location using the pointer to make it follow the subject properly. If necessary, you can go a frame at a time, dragging the stroke to a better position every time it fails to follow the feature you're using it to isolate.

  Track All Frames Backwards: Continuously tracks from the current frame all the way to the beginning of the clip.

Stop Tracking: Stops tracking, in cases where there's a problem with the track and you want to make a change.

Track Forwards and Backwards: Tracks from the current frame all the way to the end of the clip, then returns to the original tracking point and tracks backwards to the beginning of the clip.

Track All Frames Forwards: Continuously tracks from the current frame all the way to the end of the clip.

Track One Frame Forwards: Tracks one frame forward and stops. Useful if you're tracking frame by frame to watch the progress of a particularly complicated bit of motion. If necessary, you can go a frame at a time, dragging the stroke to a better position every time it fails to follow the feature you're using it to isolate.

Go To Last Frame of Tracked Area: Moves the playhead to the last tracked frame of a range of tracked frames in preparation for tracking forwards if there are untracked frames at the end of the clip.

- **Stroke tools:** Two tools at the right let you choose whether to draw strokes to identify the feature you want to isolate or identify things that aren't the feature in order to eliminate unwanted excursions in the resulting mask. The plus eyedropper adds an area to the mask; the minus eyedropper removes an area from the mask.
- **Invert Mask:** A button lets you invert the resulting mask in cases where you want to use the feature analysis of this palette to isolate everything except the feature or features being analyzed.
- **Mask Overlay:** Turns on an onion-skinned overlay with which to see what parts of the image are being masked alongside which aren't, so you can continue to refine the result by adding, moving, or deleting strokes. The isolated part of the mask is tinted translucent red.

Stroke List

Once you start drawing strokes to identify features for mask generation, they appear in this Stroke list.

- **Stroke list header:** The header, at the left of the Stroke list, has controls for selecting, enabling/disabling, and naming each stroke (if you need that level of organization). Right-clicking any stroke in its header reveals controls to Reset Tracking Data and change the mask type (feature or not feature).

  In *Object* mode, this is just a flat list of strokes, each of which help to either define the object you want to isolate, or the background.

  In *Person* mode, this is just a flat list of strokes, each of which help to either define the person you want to isolate, or the background.

  In *Features* mode, an additional drop-down menu lets you choose which specific feature you want to identify with a guidance stroke. All strokes are sorted hierarchically by the feature they correspond to, so for example each Face stroke appears underneath a Face title bar. The title bar for each feature has a toggle control that lets you turn that feature off and on. When off, you disable that feature's contribution to the overall mask being generated.

- **Stroke timeline area:** A Timeline ruler shows the duration of the current clip you're creating a mask for. Each stroke in this list has a track that displays how many frames of each stroke have been tracked. As you track each stroke, these tracks fill up with colored bars to show which frames have tracking data.

  Tracks of strokes that identify a person or object are blue, while tracks for strokes identifying things that aren't the feature are red. Using this timeline, you can keep track of which strokes need to be tracked, and manipulate the tracking data as necessary to obtain a useful result.

Mask Adjustment Controls and Matte Finesse

There are two sets of controls for refining the mask that's output by the Magic Mask palette. The first set of controls, at top, let you adjust how the mask is generated based on the analysis data, which lets you refine the mask result based on characteristics of the image. These include:

- **Quality:** Two options let you choose a tradeoff between quality and performance. Faster lets you generate a lower quality mask more quickly, that's suitable for garbage matting. Better generates a higher quality mask with more detail, that's more processor-intensive.
- **Smart Refine (Person Mode):** This control lets you expand or contract the resulting mask based on the analysis of the image, such that expanding the mask doesn't expand it deeply into surrounding parts of the image that aren't connected to that person. This operation does not introduce softness. Instead, it enlarges or shrinks the overall mask generated by this palette. 0.5 is unity, 0 is the maximum amount of expansion, while 1 is the maximum amount of contraction.
- **Refine Range (Object Mode):** This control lets you adjust the sensitivity of the resulting mask based on the analysis of the image. This lets you fine tune the mask to encompass more or less of the selected object. 30 is unity, 100 is the maximum amount of sensitivity, while 1 is the minimum amount of sensitivity.

A second set of mask manipulation controls are for manipulating the mask after it's been generated. Most of these are the same Matte Finesse controls that are available in the Qualifier palette, which are useful for trying to fix issues with problem masks, or soften the edges when you need to have a more feathered result.

For more information about the Matte Finesse controls, *see Chapter 135, "Secondary Qualifiers."* There is one additional control, however, that's unique to the Magic Mask palette.

- **Consistency:** After you've tracked each stroke to follow the subject over the duration of the clip, this setting lets you choose how much temporal smoothing is necessary to ameliorate jitter in the edges of the resulting mask in areas of low confidence, such as frizzy hair or translucent clothing. Higher settings apply more smoothing to the edges of the mask but are more processor intensive and may affect how closely the mask follows motion in the image. Lower settings will be faster and more accurate but may allow more edge jitter in the resulting mask, which can be distracting in the final adjustment you're making. This parameter defaults to 0, so your first application of Magic Mask will always begin with the most accurate (and potentially most active) application of this feature's analysis.

IMPORTANT: Consistency requires a stroke to have a duration of at least a few frames in order to function correctly. This requires you to track each stroke to follow the motion of the camera and subject in order to extend the duration of each stroke. Because Consistency is trying to eliminate one or two frame "noise" in the shape of the mask, strokes of short duration may end up having their effect eliminated.

Choosing What to Isolate

This section elaborates on the different choices that are available for isolation and offers tips for what each choice is good for.

Object Mode

Object mode is the easiest choice to make. Essentially, use this mode for any subject that is not a person. Subjects like cars, pets, and food are all good candidates for Object mode. The notable exception to this rule are items of clothing like shirts, hats etc. that are being worn by a human. Worn clothing is much better isolated in Person mode instead.

Drawing positive strokes in Object mode will select areas of similar contrast and color, allowing you to link complex shapes together. Generally you will need more strokes to actively define an object than a person, due to the greater variety of the shapes involved.

Drawing negative strokes in Object mode removes areas from the object that you don't want to isolate. This can be something simple like removing the wheels of a car from a mask, or more complicated like removing specific books from a mask of a bookshelf.

Person Mode

When you choose Person, every stroke you draw over someone helps to isolate that person's entire body, or however much of that person is visible onscreen. This includes all clothes that person is wearing, including their shirt, pants, shorts, dress or skirt, bathing suit, knickers, jumpsuits, hat, shoes, even armor or space suit (yes, we've tested both), whatever. Most clothing should be correctly identified as part of the isolation mask you're creating. However, excessively flowing garments may need an extra stroke or two to identify them in complex visual compositions.

Drawing negative strokes, when in Person mode, will identify everything that's not the person you're isolating; this omits both the background and/or other people from the mask being generated. Drawing negative strokes isn't mandatory; you only need to draw a negative stroke if you see a problem such as part of the background being included in the isolation mask.

Features Mode

When you choose Features, a drop-down menu appears at the top of the Stroke list. You must first choose the feature you want to isolate from this menu, and then draw strokes over the selected feature (face, hair, etc.) you want to isolate. Each feature's collection of strokes can be turned on or off to add that feature to the overall mask being created.

- **Face:** Isolates just the face and ears, including eyes and glasses. This omits hair and the neck (which is considered part of the torso). Facial hair, particularly bigger beards, will usually be omitted from an initial stroke made on exposed skin of the face, so you can work on just the skin if you want. However, an additional stroke on the beard will include it in the face isolation.
- **Hair:** Isolates just the hair, stopping at the bangs and ears, and omitting as much of the face as possible. Curly, frizzy, or wispy hair will produce oversized masks encompassing as much of the hair detail as possible. This tool does not create fine transparency. Fine and irregular hair detail can cause jittery edges, but this can be ameliorated using the Consistency control.
- **Torso (Exposed Skin):** Isolates exposed skin above the waist and below the face, excluding the arms. This is the selection you want to enable if you want to isolate the neck, neckline, and any part of the chest that's exposed when wearing v-necks, plunge necks, tank tops, crop tops, or bikini tops.
- **Clothing (Top):** Any clothing above the waist. Exposed skin is omitted.

- **Clothing (Bottom):** Any clothing below the waist. Exposed skin is omitted.
- **Arms (Exposed Skin):** The exposed parts of arms or hands. Shirt and dress sleeves are omitted, as are sun sleeves.
- **Shoes:** Most styles of shoes will be isolated.
- **Legs (Exposed Skin):** Isolates exposed skin below the torso, excluding socks and leggings.
- **Hat:** Most styles of hats will be isolated, although thin accessories such as streaming ribbons or feathers might not be included.

Remember, no matter what feature you've selected to isolate, you can always draw negative strokes to omit other parts of the person or their clothing that are erroneously being included in the mask.

IMPORTANT: When you're drawing strokes in Features mode, accidentally drawing a stroke over a feature other than the one that's selected in the drop-down menu at the top of the Stroke list will result in a completely incorrect mask. If you see this happen, delete the stroke you just made, double-check which feature is currently selected, and either redo the stroke or choose the correct feature you want to isolate.

Identifying More Than One Person

In both Person and Feature mode, you can add strokes to identify more than one person, or more than one person's features. There's nothing special you need to do, simply draw strokes over each person you want to isolate, or over the same feature of each person you want to include (for example, drawing stroke over three people's faces in Face mode).

You can draw strokes over multiple people to isolate them together in the same mask.

Using Matte Finesse Controls

There are plenty of situations where a seemingly problematic mask can be improved using the Smart Refine and Matte Finesse controls at the right of the Magic Mask palette. If the mask is only a few pixels off, and the color adjustment you want to make is reasonably subtle, you can probably use Blur Radius and In/Out Ratio to create a soft edge that falls off just at the outer edge of the subject (so as not to create a halo effect) with which to make your adjustment.

(Top) The hard edges of the initial mask aren't quite close enough to the edges of the woman's arm to make a subtle adjustment, (Bottom) Using the Blur Radius and In/Out Ratio controls to create soft edges that don't extend past the subject to make a useful mask

Using Magic Mask as a Garbage Matte

In situations where the outer edge of a person is not being detected closely enough for Magic Mask to give a useful result for a more extreme color adjustment, you're probably better off expanding the result into a closely-fitting garbage matte to use for isolating the person or features using other techniques, such as a keyer in the Qualifier palette. Even for this purpose, you'll find using

Magic Mask is typically faster than rotoscoping a relatively close garbage matte over a moving figure using windows.

(Top) The initial mask isn't quite close enough to the edges to make an extreme adjustment, (Bottom) Using the Mode/Shape/Radius/Iterations/Blur Radius controls to expand the matte to be a garbage matte for use with other keys

Dealing With Hair

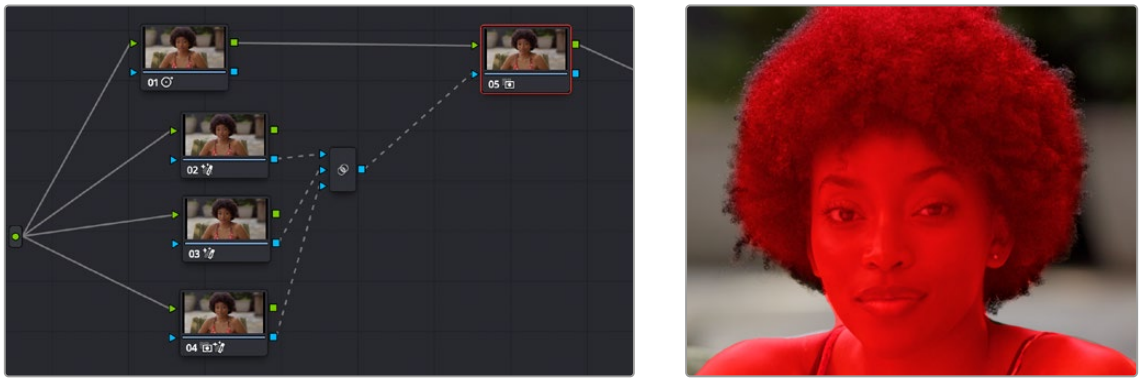
Wispy or frizzy hair, individual strands of hair being thrown back, and tips of dreadlocks or heavily moussed hair that comes to points will often require special handling with this tool. Keep in mind that the Magic Mask tool does not specialize in soft translucent mask edges like a keyer does. When it comes to hair styles that are loose and free, in many situations you may be able to finesse an acceptable result using the Matte Finesse controls to expand a softened version of the matte to encompass the entire hairstyle.

If this interferes too much with the edges of other features of the subject you're isolating, you can create a dedicated hair mask in Features mode by drawing Hair strokes. You can then use the Matte Finesse controls at the right of the palette to create softened edges that work well with the outer boundary of the hair style you're isolating.

Creating a soft-edged hair mask

At this point, you can try doing different color adjustments using two different correction nodes, one for the subject's hair, and another using Magic Mask to isolate everything but the hair.

Alternately, if you want a single matte with which to isolate the entire subject, you can then use additional instances of the Magic Matte tool (one per node), using one node to isolate just the face and body without the hair, and a third node to isolate the entire subject but with a very soft edge. Then, you can use a Key Mixer node to combine all these masks together with the original hair mask you created, with which to feed a complete key to another node used to make the correction.



(Left) Nodes 2, 3, and 4 are creating three different masks that are combined using a key mixer and connected to the Key input of Node 5 to make an adjustment, (Right) The final result of this three-mask approach.

While hair with soft edges can be a challenge, Magic Mask excels at many elaborate hair styles with detailed shapes and hair accessories, including jewelry and ribbons. For example, the stylized hairstyles found in European and Chinese period movies and shows give the DaVinci Neural Engine no trouble at all, particularly as these styles are usually tightly bound with no wispy hair.

Asymmetrical hairstyles may require extra strokes to identify hair that's significantly longer on one side of the face. This may also be true for unorthodox hair styles, such as hair that's been sculpted into distinct sculptural shapes. Lastly, tight braids that expose skin on the scalp are also challenging for

the kind of hard masks that Magic Mask produces, so you're better off using Magic Mask as a garbage matte and using a keyer to create a detailed soft mask to use in these instances.

About Hats

Magic Mask works with an incredibly wide variety of hats from all time periods. On hats, tassels or details like feathers can be a problem (in testing, the feather on Errol Flynn's cap in Robin Hood couldn't consistently be included, even though the cap itself was no problem). Additionally, veils that are part of hats may or may not be easily identified, but an additional stroke usually solves the problem.

Dealing With Accessories

Things that people are holding, such as handkerchiefs or umbrellas, are best selected in Object mode. Jewelry and watches pose a special problem, as they're typically so thin and small that they can be difficult to omit, but you may not want to include them depending on the adjustment you're trying to make. Your results will vary with the thickness of the items and the framing of your subject, but in general your results will probably be better if you simply add a stroke or two to include these items in the isolation, since omitting fine detail like a necklace can be problematic.

Adding Strokes to Guide Mask Creation

Here are some tips for how to draw strokes to analyze the image. To identify people, try starting with a single short positive stroke (blue), centered on the face or body.

Drawing the first stroke to identify an entire person

Depending on the result, more strokes may be needed to differentiate an arm or frizzy hair from the background. If you're adding a stroke to an arm or hair, don't put it right at the edge; the goal is not to trace the subject, but to use strokes within the body of the subject to clarify what features belong to the subject, and which do not.

Adding a stroke to the arm to include it as well

As you do this, resist the urge to use too many strokes. One stroke might well be all you need, or you might need two or three, but using more than five strokes for any subject or feature may cause more problems than it solves.

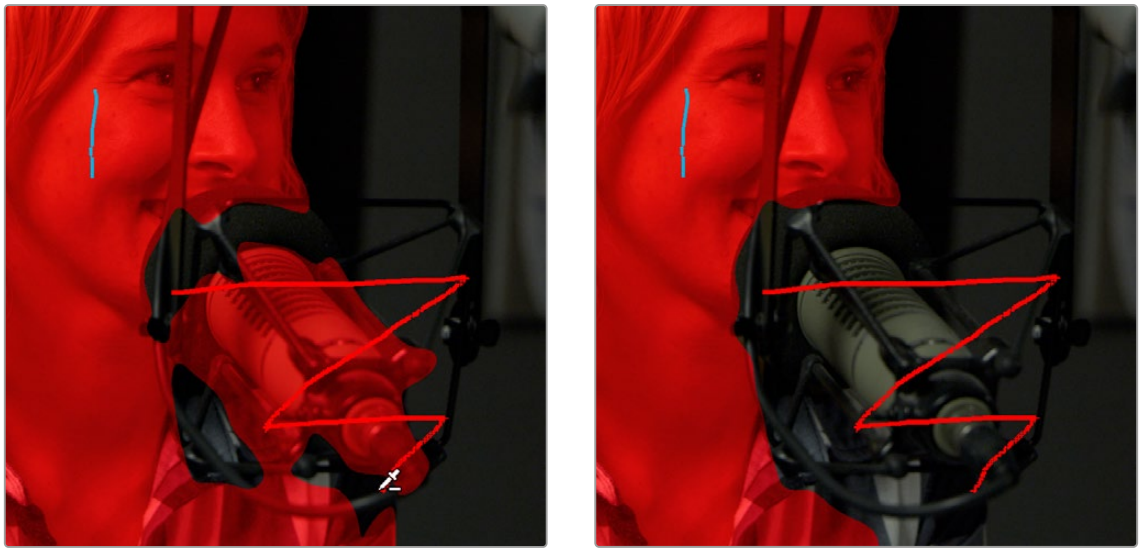
Adding negative strokes to the reflection to remove

To identify faces, try starting with a single short stroke in the middle of the face, along the nose, or from eyes to the lips. Depending on the result, you may need additional strokes to identify the chin, a beard, or to distinguish the forehead from wispy hair.

Drawing strokes to identify a face; notice that additional strokes are needed to include the beard.

It's a good idea to start with a single stroke, then track the stroke through the duration of the clip (described later in this section). Over the entire clip, you'll see which parts of the mask may exhibit problems. This will guide where you put additional strokes, in order to more clearly identify the person versus the background, in order to clean up the resulting mask. As you add additional strokes, track those as well and see how things go.

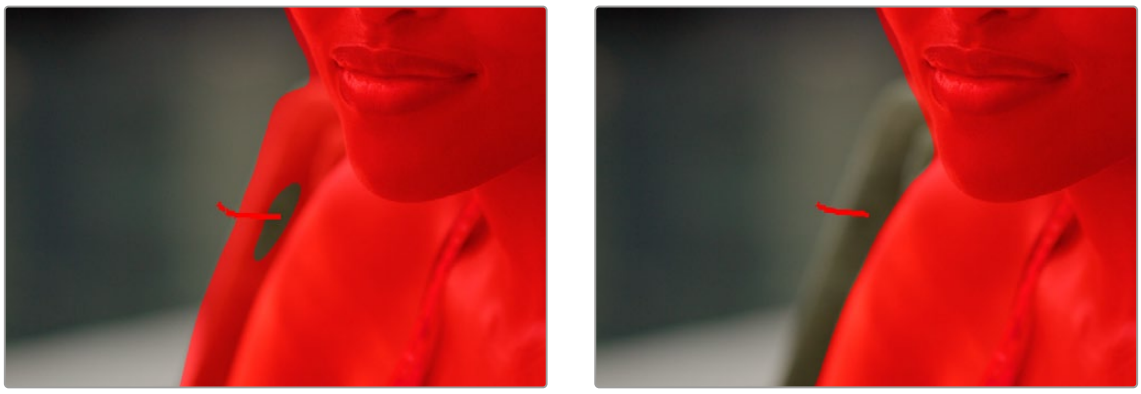
If you notice parts of the background that are erroneously added to the mask, you can add a negative stroke (red) to clarify that those parts of the image should not be isolated. Short strokes, longer strokes, and zig zags are good for backgrounds. Since strokes just help the analysis update the mask, you can try different types of strokes to see what works best, and delete any stroke that doesn't give good results. As with positive strokes, don't use more strokes than are absolutely necessary to get the result you want.



(Left) The microphone incorrectly identified as part of the woman being interviewed, (Right) Drawing negative strokes to identify the microphone as background, using a zig-zag pattern to tag the entire microphone

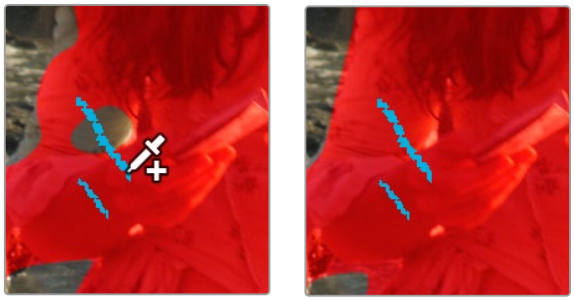
Similarly, if you're isolating features such as a face, and you find other features, such as hair, getting in the way, you can draw a negative stroke on the hair to identify it as not part of the face.

If there's a "hole" in the resulting mask that's actually part of the background and not the subject, you can try drawing a stroke connecting that hole to the rest of the background.



Drawing strokes to connect the background with itself, to remove part of the mask that's not part of the person

If there's an "island" in the mask that's actually part of the subject and not the background, you can try drawing a stroke across the island that connects one solid part of the mask to itself.



Drawing strokes to fill an island in the subject being isolated

Of course, extracting a mask using strokes is only the first part of creating a useful mask. The Quality, Consistency, and Smart Refine controls let you refine the stroke analysis of the image to create the best tradeoff between performance and quality for the type of mask you need. These controls work hand in hand with the strokes you draw to extract a mask. A set of Mask Finesse controls then let you adjust the resulting mask to manipulate and soften it, to better suit whatever adjustment you're trying to make. All of these controls are described earlier in this section.

Managing Strokes in the Stroke List

When you draw a stroke, it appears in the Stroke list. By default, all strokes last for the duration of the clip to which they're applied, so if you draw a stroke to identify a figure that's not moving, there's no requirement to motion track the stroke. Strokes in Person mode appear in one long list, while strokes in Features mode appear hierarchically, with the strokes for each feature separated by the title of each feature. Once a stroke appears in this list, it has the following controls.

- **Enable/disable feature:** In Features mode, once you draw at least one stroke to identify that feature, the title of that feature appears, underneath which is organized all the strokes for that feature. A toggle next to the feature name lets you turn that feature's contribution to the overall mask on and off.

- **Enable/disable stroke:** Each individual stroke in this list has a blue dot that lets you turn that stroke's contribution to the overall mask on or off.
- **Stroke Timeline Area with Stroke Tracks:** The stroke track for each stroke lets you keep track of and manipulate the animation of strokes to follow camera and subject motion. Blue or red frames in this track let you see at a glance how much of each stroke has been motion tracked; blue frames for positive strokes, red frames for negative strokes. You can also use these tracks to identify frames where you'd like to mute that stroke's contribution to the final mask and to keep track of which frames have been muted. You can draw a bounding box within the stroke track around however many frames of however many strokes for which you want to delete motion tracking.

Stroke Duration

When you first draw a stroke, that stroke has a duration of one frame, located at the timecode position of the playhead when you drew it. If you move the playhead to the left or right, you'll see the stroke disappear. If you want one or more strokes to continue analyzing the subject for the duration of that shot, you need to use the Motion Tracking controls to track the stroke to follow along with the motion of whatever it's drawn on top of. As a stroke is tracked, its duration increases to cover the entire range of tracked frames. If at any point a stroke outlasts its usefulness, such as when a person walks off frame, you can stop tracking that stroke when it's no longer necessary and it will stop contributing to the analysis.

This is useful, because often you'll want to place strokes to deal with analysis issues that only last for a few frames, to fix a hole in the mask that only appears briefly. Just be aware, you can't simply draw a stroke and move on to the next shot; you must track at least one stroke to last for the duration of a subject's time on screen for that subject to be continuously masked.

Tracking Strokes to Follow Subject Motion

You can think of each stroke you've drawn as a persistent eyedropper that samples the image that overlaps it. The mask that results from all strokes' collective analysis of the image is generated live over each frame of the clip. This means that if the camera or the subject moves, you need to motion track or otherwise adjust the position of each stroke to follow along with the motion, so the subject continues to be correctly identified. You also need to make sure that each stroke is able to analyze what it's supposed to, and turn off strokes that can't for whatever reason.

> **TIP:** Magic Mask is a processor-intensive operation, so to accommodate users of less powerful workstations, there is a Use Fast Tracking option available in the Magic Mask palette's Option menu, which speeds up the process of tracking at the expense of potentially less accurate tracking for fast or erratically moving subjects.

Methods of Moving Strokes to Follow Subject Motion

For these reasons and more, there are multiple methods of manipulating strokes to refine the final analysis.

- **Motion Tracking:** A set of tracking controls at the top of the Magic Mask palette let you motion track one or more strokes to follow the camera and subject motion in a clip. Every frame that's motion tracked effectively has a motion-tracked reference frame placed on it that moves the stroke to a new position.

- **Reference Frame:** Any time you drag a stroke from its original position in the Timeline, you create a static reference frame at that frame that instantly moves the stroke from its previous position to the new position at that frame. Because these are similar to static keyframes, there's no motion interpolation from one "keyframe" to the next in order to create animation. Instead, a reference frame in the Magic Mask palette is a simple frame-by-frame operation. Every time you move a stroke at a new frame, you change the stroke's position at that frame from that point forward, without changing stroke position on any other frame that's been previously tracked.

  If this seems simplistic, keep in mind that the goal is not to create beautiful stroke animation with this tool. You only need to move each stroke to follow along with whichever subject or background feature it's supposed to be sampling in each frame. The only important thing is that, in every frame, the stroke overlaps a suitable part of the feature you're isolating to create the appropriate mask. If the stroke itself jumps around abruptly, that doesn't matter so long as the mask that's generated is good. This means that even if you're stuck doing a limited amount of frame-by-frame animation to make a stroke follow along with a troublesome feature (such as a veil flapping in the wind), it'll go pretty fast, because in each frame you're just dragging the stroke to overlap the feature wherever it happens to have moved. This repositioning doesn't have to be smooth, just accurate.

- **Combining Tracking and Reference Frames:** Since each frame that's motion tracked is effectively keyframed, manually dragging a stroke on a frame that's already been tracked overrides the tracking data at that frame with a reference frame that records the new position of the stroke at that frame. If there's no more tracking data, either before or after that reference frame, then the stroke disappears until you do more tracking. If there's tracking data immediately after a reference frame, then the stroke jumps to the position dictated by that tracking data.
- **Deleting Stroke Tracking at Specific Frames:** To accommodate cases where a subject you're isolating moves behind something and becomes hidden for a range of frames, you have the ability to delete stroke tracking for one or more frames. This lets you eliminate the stroke for however many frames the subject you're tracking is obscured and cannot be sampled. This makes it easy to deal with features that come and go over the duration of a clip, since you can delete stroke tracking over however many ranges of frames the feature disappears. If you've muted frames by mistake, you can either undo or re-track the stroke over those frames.

  To delete tracking frames, draw a bounding box on the stroke tracks over the range you want to delete, and then choose Clear Selected Track Data from the Magic Mask option menu.

Option Menu Commands for Removing Strokes and Tracking

The Option menu of the Magic Mask palette presents a number of commands for clearing either strokes or stroke tracking data.

- **Clear All Strokes:** Deletes every stroke in the Stoke list, along with tracking.
- **Clear All Strokes of Current Frame:** Deletes the tracking data at the current position of the playhead on all strokes in the list.
- **Clear All Strokes from In to Out:** If you use the I and O keys to set In and Out points in the Stroke Timeline, this command deletes all tracking data on all strokes within that range.
- **Clear Selected Stroke from In to Out:** If you select a stroke in the Stroke list, and then use the I and O keys to set In and Out points in the Stroke Timeline, this command deletes the tracking data of selected strokes within that range.
- **Clear Selected Track Data:** If you drag a bounding box around tracking data for one or more strokes, this command deletes all tracking data within the box.

An Example Stroke Tracking Workflow

By combining motion tracking, manual reference frames, and stroke muting, you'll be able to make short work of isolating most moving subjects. The following procedure illustrates how you might use these techniques together to make the strokes you've drawn follow along with the features you're isolating.

To track one or more strokes to follow a subject:

1. If necessary, move the playhead to the frame where you want to begin isolating the subject you want to mask. For example, if you're isolating a person walking into the room through a door, you probably want to begin your work on a frame where the person is already in the room, and work your way backward and forward from that frame. If your subject is already fully visible at the first frame of the shot, you can start there.
2. Draw at least one stroke identifying the subject or feature you want to isolate. You cannot track a stroke to follow the features unless there's at least one stroke.
3. Choose whether you want to track all strokes or only selected strokes. By default, all existing strokes with at least one frame in the Stroke Timeline at the position of the playhead will be tracked. However, you can choose to track only selected strokes in the Stroke list by choosing Track Selected Stroke Only in the Magic Mask palette's Option menu.
4. Click the Track Forwards to End or Track Backwards to Beginning buttons if you want to motion track the strokes over the remaining duration of the clip.

   By default, each stroke is tracked to follow whatever image detail immediately surrounds it; you don't have to define a tracking region, this is done automatically. As tracking proceeds, the tracking bar for each stroke will fill up showing you which frames have been tracked, and which have yet to be tracked. Meanwhile, each stroke being tracked will transform to follow along with simple position and rotation changes in the subject. However, things that obscure the subject, as well as more extreme movements, may cause problems.

   Strokes that are tracking a feature that moves off screen are automatically excluded from tracking at the frame where the feature is completely off screen, even if that feature returns onscreen in a later frame.
5. (Optional) If a problem occurs during the track, such as the subject being occluded behind something else in the frame (for example, a person's face moves behind a tree as they walk), click the Pause Track button. You can deal with problems in the track in the following ways:

   a) **If a stroke has completely moved off of the subject:** For example, you're tracking a stroke to follow a person and they turn around 180 degrees, so the stroke moves off onto the background. To fix this, pause the track, move the playhead to the first frame where the stroke hasn't followed the subject properly, then use the pointer to drag the stroke onto another part of the subject that's clearly visible. On each frame where you drag the stroke to a new position, a new reference frame will be automatically added. Continue this process until the subject's motion is consistent enough to be trackable again, and you can then resume tracking.

   b) **If a stroke has moved onto something that's partially obscuring the subject:** Pause the track, drag a bounding box over the frames where the track is having a problem, and choose Delete Selected Tracking from the Magic Mask Option menu to clear the bad tracking data. Then, move the playhead to the first frame of the deleted tracking data, and use the pointer to drag the stroke onto any part of the subject that's visible to either side of the occlusion. Move the playhead to each successive frame, and drag the stroke onto whichever part of the subject is visible from behind the occlusion, until the subject moves past the occlusion. At that point, you can use the Track Forwards to End or Track Backwards to Beginning buttons to continue tracking as usual.

c) **If the subject becomes completely hidden:** Clips where the subject appears and disappears over the duration of a clip can be resolved by deleting the stroke or strokes on that subject over all frames where the subject is obscured, so that strokes only sample the image when the subject is visible and thus able to be isolated. You can delete one or more strokes by dragging a bounding box over a range of frames, and then choosing Clear Selected Track Data from the Magic Mask Option menu.

d) **If a stroke is having trouble following the subject:** If the subject you're tracking is moving too fast, too irregularly, or is changing shape too greatly for the tracker to give a good result (for example, someone lifts their arm towards the camera), you can track through the problem area of the clip one frame by frame using the Track Forward 1 Frame or Track Backward 1 Frame buttons, and then use the pointer to manually drag the stroke to follow along with the subject as you go. Once the problem motion stops and the motion of the subject becomes more regular, you can use the Track Forwards to End or Track Backwards to Beginning buttons to continue tracking as usual.

e) **If the subject is moving off the frame:** If you've drawn a stroke in the middle of someone's face, and their face is moving off screen, you can manually reposition the stroke on the last few frames before the subject completely exits so that stroke continues to identify what parts of the face are still visible even though the part of the face it was originally following becomes hidden. Once the face completely exits the frame, you can mute the stroke for the rest of the shot.

6 (Optional) If you only tracked the stroke's movement over part of a shot, you can click the Jump to Start or Jump to End buttons to move the playhead to the first or last tracked frame, in preparation for tracking from that frame onward.

Chapter 138

Motion Tracking Windows

While Power Windows can be manually keyframed to follow a moving subject you want to isolate, this chapter shows how you can use the powerful cloud and point-based motion tracking controls in DaVinci Resolve to make Power Windows follow along with the motion of subjects and the camera in the fastest, easiest way possible.

Then, numerous techniques are presented for dealing with complicated tracking scenarios and common problems that arise for subjects that are difficult to track.

Motion Tracking Windows

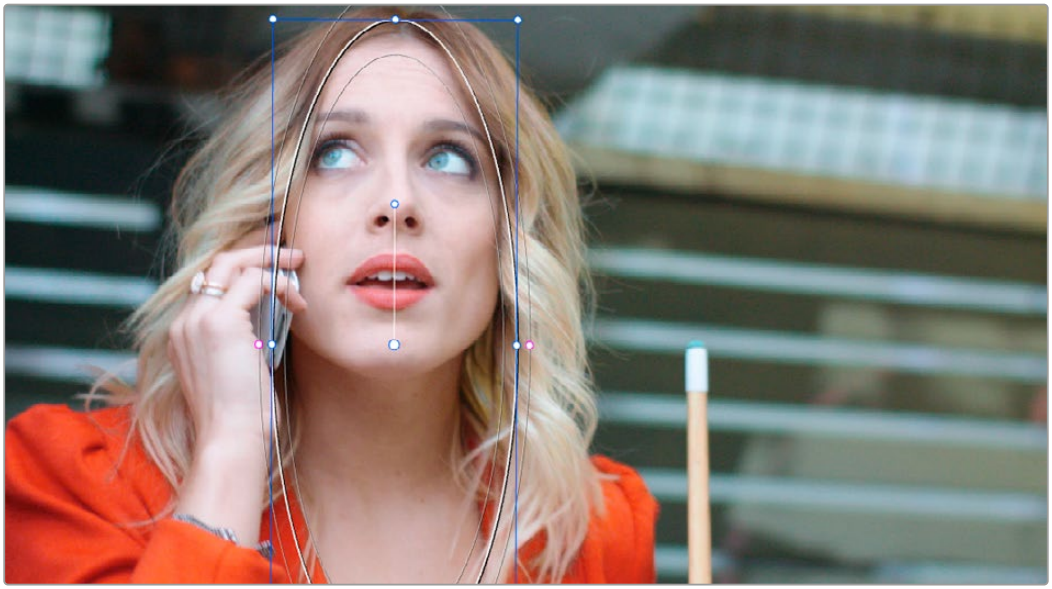
The Tracker palette has three modes, available from the Palette menu.

- In Window mode, the tracking controls let you match the motion of a window to that of a moving feature in the frame.
- In Stabilizer mode, the same underlying technology is used to smooth or stabilize the motion within the entire frame.
- In FX mode a Point Tracker can be used to animate ResolveFX or OFX plugins with positioning controls.

For more information about the FX and Stabilizer modes,
see Chapter 150, "Sizing and Image Stabilization."

DaVinci Resolve has an incredibly simple, yet powerful, 3D cloud tracker that allows you to track quickly and accurately any Power Window (Circular, Linear, Polygonal, Curve, or Gradient) to follow any moving feature. This avoids the need to use dynamic keyframes to manually animate a window's position.

In particular, you can use the tracker to match a window's position, size, rotation, and its pitch and yaw in 3D space to either foreground or background elements that move within the frame.



A Power Window tracking a woman's face

Simple Tracking Using the Tracker Menu

The simplest way to track a feature using a Power Window is to use the commands found in the Color > Tracker menu. These commands include:

- **Track Forward (Command-T):** Tracks a window to a feature from the current position of the playhead forward, ending at the last frame of a clip.
- **Track Reverse (Option-T):** Tracks a window to a feature from the current position of the playhead backward, ending at the first frame of a clip.

- **Track Stop (Command-Option-T):** Interrupts any track. This is useful for letting you cancel a long track that goes wrong (the Stop button of a control panel stops tracking as well).
- **One Frame Forward (Option-Right Arrow):** Tracks a window to a feature one frame forward from the current position.
- **One Frame Reverse (Option-Left Arrow):** Tracks a window to a feature one frame backward from the current position.

Most window tracks are easy to accomplish using these three commands.

To track any Power Window to match a moving feature within the frame:

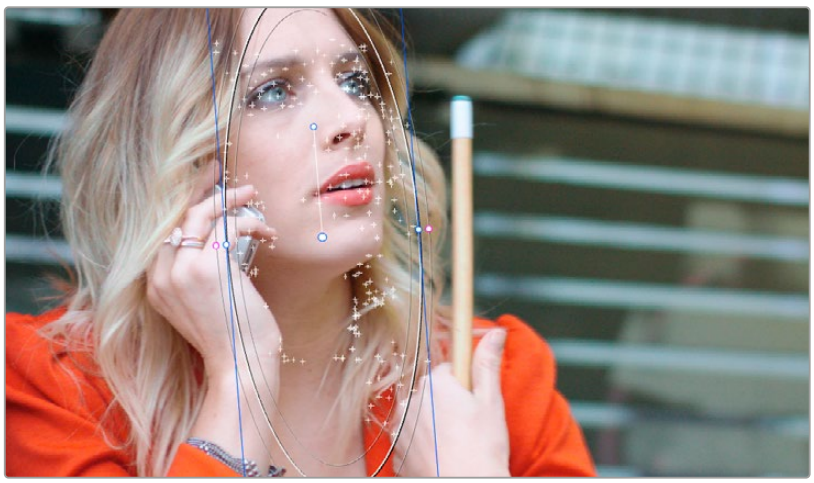
1. Move the playhead to the frame of the current shot where you want to begin (you don't have to start tracking at the first frame of a shot).
2. Turn on any window, and adjust it to surround the feature you want to track.

   Typically, you'll have done this anyway, for example, framing someone's moving face with a Circular window to lighten their highlights.
3. To initiate tracking, do one of the following:
   - Choose Color > Tracker > Track Forward (press Command-T).
   - Choose Color > Tracker > Track Reverse (Option-T).

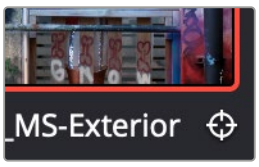
DaVinci Resolve automatically opens the Viewer page, places a series of tracking points within the window you've created, and performs the track from the current frame; forward to the last frame or backward to the first frame.

DaVinci Resolve analyzes a cloud of tracking points that follow the vectors of every trackable group of pixels within the window you've created, and the results are fast and accurate. After tracking, the window you've placed automatically moves, resizes, rotates, and skews to match the motion of the feature you're tracking.

Once a clip has tracking data applied to one of its windows, a small tracking icon appears within that clip's icon in the Thumbnail timeline.



Object tracking in progress. Tracking points are automatically placed over trackable features of the image



A tracking icon in the top left corner of the Thumbnail timeline shows that clip has been tracked

If the track you've performed is unsuitable, you can reposition the window to cover a different area of the subject you're trying to track, and initiate tracking again. New tracking data overwrites any previous tracking data applied to that window.

Once you're satisfied with your track, you can continue to resize, reposition, or reshape the window being tracked. Tracking data is separate from the window transform parameters (which can be keyframed), so changes you make to a window offset it from the originally tracked path.

Tracking Windows Across Transitions

When you track a window that crosses a transition boundary (for example, a dissolve from one clip to another), DaVinci Resolve will automatically continue the track for the full extent of the video under the transition.

Tracking Windows When You'll Be Exporting Media With Handles

When you track windows to match moving features in a clip, the windows are only transformed on frames with tracking data. In Round Trip workflows where you add handles to the graded clips you render for editorial flexibility in the footage you deliver, you need to make sure that you track all windows from the beginning to the end of these handles to make sure that, if an editor actually trims any of the clips you give them to use the handles, all windows are doing what they should.

An easy way to do this is to choose View > Show Current Clips With Handles to display each clip you select in the Timeline with handles defined by the "Default handles length" setting in the Editing panel of the User Preferences. Make sure that the "Default handles length" is equal to the handles you export using the "Add X Frame handles" option in the Render Settings list of the Deliver page. With each clip's handles made visible in this way, you can easily track windows along every frame you'll be rendering.

Simple Ways of Working With Existing Tracking Data

If there's a portion of a shot that you haven't tracked (for example, you started tracking at a later frame, or you ended tracking before the end of the shot), then the window you're tracking remains wherever it was at the first or last frame that was tracked. If you want to fill in these gaps, you can always move the playhead to the first or last frame that was tracked, and then use the Track Backward or Track Forward command to track the rest of the frames in that shot.

Tips for Better Tracking

In situations where a feature changes shape in such a way as to confuse the tracker, you can try tracking a smaller part of the feature by using a smaller window. Once you've achieved a successful track, you can resize the window as necessary, and it will have no effect on the track that's already been made.

Also, if you're tracking a feature that moves behind something onscreen and disappears for the rest of the shot, there's an easy way to avoid having an awkward window sitting in the middle of the scene. You can use dynamic keyframes to animate the Key Output Gain parameter (in the Key tab of the Color page) to fade from the correction's full strength of 1.0 down to 0, the value at which the correction disappears, along with the window itself.

Tracking One Frame at a Time

You can click the “track one frame forward” or “track one frame backward” buttons in the Tracker palette to track a moving feature one frame at a time, making it easier to make adjustments to follow a difficult track when you’ve set tracking to Frame mode (by clicking the Frame button).

In Frame mode, you can keyframe window transformations to more faithfully conform to troublesome motion as you’re moving one frame at a time through the track; manual changes to a window’s position will be keyframed to create frame-specific transformations, rather than used to offset the entire tracked motion path as in Clip mode. When you add multiple keyframes in the Tracker graph, animation will be automatically interpolated from keyframe to keyframe.

Copying and Pasting Tracking

There will be plenty of times you’ll apply multiple windows to a single moving subject, such as a car, when you can use a single motion track for all the windows. Commands in the Option menu let you copy and paste track data from one window to another within the same node, saving time when you want several windows tracking together as one.

To copy track data from one window to another:

1. Open the Window palette, then select a window that has tracking applied to it (indicated by a tracking badge in the corner of the shape icon), and choose Copy Track Data from the Option pop-up.
2. Select another window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

   You can also copy tracking from the FX mode of the Tracker palette and paste it to a window, in case you want to use the same tracking data for both an effect and a window.

To copy track data from an FX track to a window:

1. Open the Tracker palette, choose the FX mode that contains the tracking data you want to copy, and choose Copy Track Data from the Option pop-up.
2. Open the Window palette, select a window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

Tracker Palette Controls in More Detail

You can easily combine object tracking and keyframing to animate windows. For example, you’ll typically use object tracking to make a window follow the position and orientation of a moving feature, but you can add dynamic marks to the window track of the correction in the Color page with which to alter its size and shape to better conform to a feature’s changing form.

Controls in the Window Tracker Palette

Occasionally, you’ll run into a shot that doesn’t quite track well enough using the Tracker menu’s simple controls. In these cases, the Viewer page provides the complete set of object tracking controls that can be used to modify tracking operations in different situations.

The Tracker palette

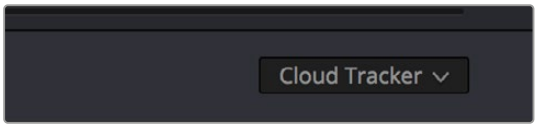
The object tracking controls are divided into seven groups.

Tracker Palette Modes

The Tracker palette's Option drop-down menu lets you choose between Window mode (for matching a window to the motion of a feature in the frame), Stabilizer mode (for subduing unwanted camera motion; for more information on Stabilizer mode, *see Chapter 150, "Sizing and Image Stabilization."*), and FX mode (for tracking position to be used with Resolve FX or Open FX plugins).

Types of Tracking

A pop-up menu below the Tracker graph lets you choose whether to use the Cloud Tracker or the Point Tracker. There are three options:

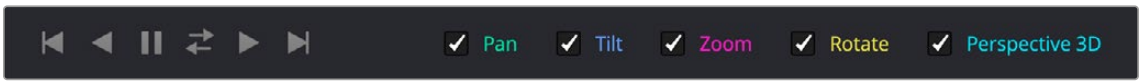


The tracker type pop-up

- **The Cloud Tracker:** Automatically analyzes all parts of the image for trackable points, and uses these to automatically figure out the motion in the shot that you want to use to move a Power Window or stabilize a shot. This tracker type is great for quickly tracking a window to match the movement of almost any feature, with a minimum of work.
- **The Point Tracker:** Lets you create one or more tracker crosshairs that you can manually position in order to track specific features in the shot. The more crosshairs you create and position, the more accurate the track can be. The Point Tracker is incredibly useful in situations where you need to follow the motion of a very specific feature in the frame. It can also be useful in cases where you want to stabilize a shot that has many subjects moving in different directions, and it's difficult to obtain a good result with the Cloud Tracker.
- **IntelliTrack:** Is a AI tool that doesn't use predetermined rulesets or heuristics. Instead, it is trained on real world examples. This makes it less likely to fail in scenarios like tracking a subject behind brief occlusions. For most cases it will be more precise and more robust than the normal Point Tracker.

Object Tracking

The object tracking controls provide the most basic tracking functions, some of which are mirrored within the Color > Tracker menu.



Choose which type of transform you want to track before tracking

A series of five checkboxes let you turn on and off which transforms you'd like motion tracking to apply automatically to the window. These checkboxes must be selected before you perform a track in order to restrict the transforms that are used.

- **Pan and Tilt:** Enables tracking of horizontal and vertical position, when you want to transform a window to follow the location of a tracked subject.
- **Zoom:** Enables tracking of size, when you want to transform a window to resize to follow a tracked subject.
- **Rotate:** Enables tracking of orientation, when you want to transform a window to rotate with a tracked subject.
- **Perspective 3D:** Enables tracking of pitch and yaw in 3D space, when you want a window to skew to follow the orientation of a tracked subject within the scene. Good when you want the window to "stick" to a surface.

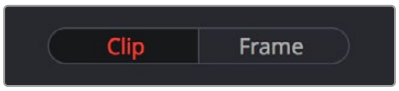
NOTE: Once tracking or stabilization has been done, disabling these checkboxes does nothing to alter the result. To make changes, you need to enable or disable the necessary checkboxes first, and then reanalyze the clip.

After you've defined the transforms you want to use for the track, the analyze controls let you proceed with the analysis of the subject being tracked.

- **Track One Frame Reverse button:** Motion tracks a single frame in reverse. Useful for slow tracking of difficult subjects that may require frequent correction.
- **Track Reverse button:** Initiates tracking from the current frame backward, ending at the first frame of the clip. Good for tracking backward when your best starting point is somewhere within the middle of the shot.
- **Pause button:** Stops tracking (if you're fast enough to click this button before tracking is finished).
- **Track Forward button:** Initiates tracking from the current frame forward, ending at the last frame of the clip.
- **Track Forward and Back button:** Initiates tracking from the current frame forward, then when finished, tracks backward from the original selected frame. This allows you a one button process when tracking from the middle of a shot.
- **Track One Frame Forward button:** Motion tracks a single frame forward. Useful for slow tracking of difficult subjects that may require frequent correction.

Clip/Frame Controls

Two buttons let you set how manual adjustments to the position of tracked windows affect the overall track.



Selecting clip or frame to apply adjustments

- **Clip:** The default mode, in which changes you make to the position of a window are globally applied to the entire track. For example, if you track a feature, and then move the window, the window moves along a motion path that's consistently offset from the original track for the duration of the clip. Use this mode if you're happy with the track, but you want to modify the window's overall shape and position relative to the motion path it's following.
- **Frame:** In this mode, changes you make to the position or shape of a window create a keyframe at the frame at the position of the playhead. Multiple keyframes are interpolated to create animation with which you can manually transform a window to solve a variety of problems. This mode is useful for rotoscoping the shape and position of windows to match a subject that's tough to automatically track. Frame mode is also useful for making corrections to individual frames that were badly tracked, for animating windows to go all the way out of frame along with a subject, or for making manual, frame-by-frame adjustments to window position to cover untrackable≈sections.

The Tracker Graph

The Tracker graph provides a visual display of the tracking data that's being analyzed. Each of the transform controls that can be tracked has an individual curve, which lets you evaluate each tracked parameter on its own, and each curve is color-coded to match the corresponding label of the tracking transforms listed above.

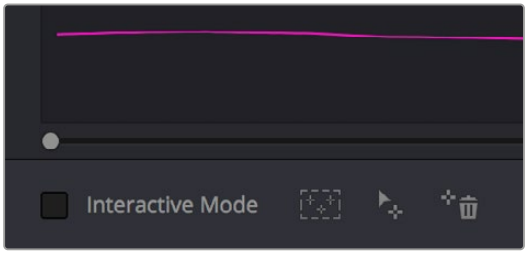
The Tracker graph showing a curve for each transform control

A vertical slider to the right of the Tracker graph lets you scale the height of the curve data within to make it easier to see it all within the graph. A horizontal slider at the bottom of the graph allows you to zoom in and out of the tracker curves, allowing you to see finer detail of the tracking paths. Above the Tracker graph, a Timeline ruler contains a playhead that's locked to the playheads in the Viewer and Keyframe Editor.

You can draw a bounding box in the Tracker graph with which to select a portion of one or more curves to delete sections of low-quality tracking data using the Clear Selected Keyframes command found in the Tracker Options menu. To eliminate the current bounding box from the Tracker graph, click once anywhere within the graph.

Interactive Mode Controls

The Interactive controls, at the bottom-left of the Tracker palette, let you make manual changes to the automatically generated tracking point cloud that DaVinci Resolve creates when you're tracking with the Cloud Tracker, so you can try different ways of obtaining better tracking results in challenging situations.



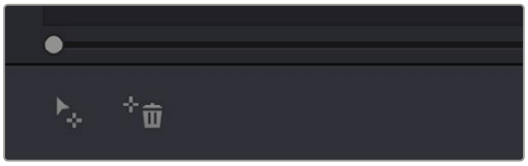
Interactive mode controls

- **Interactive Mode checkbox:** Turns the Interactive tracking mode on and off. When you enter Interactive mode, you can manually alter the point cloud that DaVinci Resolve uses to track the feature within the current window. You'll then make your track while in Interactive mode.
- **Insert:** Lets you add tracking points to whatever trackable features exist within a bounding box that you've drawn in the Viewer. Inserted tracking points are automatically placed based on trackable pixels in the image.
- **Set Point:** Lets you use the cursor (using the DaVinci Resolve Advanced control panel), to manually place individual tracking points, one by one, with which to track a feature. If there is no trackable pixel group at the coordinates where you placed the cursor, a tracking point will be placed at the nearest trackable pixel group.

  You must place at least two tracking points at different pixel groups to track rotation, and at least three to track zoom.
- **Delete:** Eliminates all tracking points within a bounding box that you've drawn in the Viewer.

Point Tracker Controls

If you're using the Point Tracker, then the Interactive Mode controls disappear, replaced by the two controls of the Point Tracker.



Point Tracker controls

- **Add Tracker:** Click to create a new tracker that's automatically positioned in the center of the frame. Once created, you can drag it using the pointer to line up with the feature you want to track. You can create as many trackers as you like. Multiple trackers are all tracked at once.
- **Delete Tracker:** Select any tracker (selected trackers are red, deselected trackers are blue), and click this button to remove it.

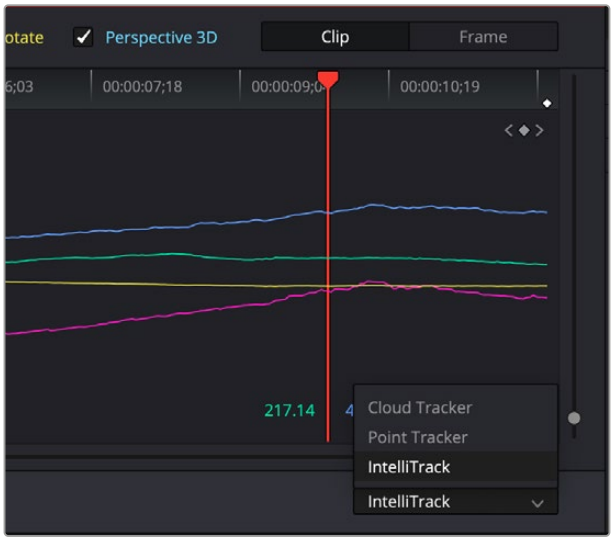
Additional Commands in the Tracker Options Menu

There are some additional commands located in the Tracker Options pop-up menu.

- **Reset Track Data on Active Window:** Lets you delete the tracking data corresponding to the currently selected window.
- **Clear Selected Track Data:** When you drag a bounding box over parts of one or more curves in the Tracker graph, this command lets you delete that part of the graph. This is useful when you want to eliminate sections of low-quality track data. Portions of curves that are cleared in this way have linear interpolation automatically applied to them, similar to if you used the Keyframes Interpolation controls.
- **Delete Keyframe:** Deletes tracker graph keyframes at the current position of the playhead.
- **Clear All Tracking Points:** Clears the tracking points in the Power Window at the frame you are on.
- **Show Track:** Turn this checkbox on to show the motion path produced by the tracking you've done.
- **Copy Track Data:** Lets you copy track data from the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.
- **Paste Track Data:** Pastes copied track data to the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.

IntelliTrack AI Point Tracker (Studio Version Only)

The DaVinci Neural Engine powered IntelliTrack point tracker is now available in the Color tracker, Fusion point tracker, and the FX tracker in DaVinci Resolve Studio. The IntelliTrack setting can be used for general tracking and stabilization tasks.



Setting the IntelliTrack mode for the Color page window tracker

IntelliTrack, like other AI tools, doesn't use predetermined rulesets or heuristics. Instead, it is trained on real world examples. This makes it less likely to fail in scenarios like tracking a subject behind brief occlusions. For most cases it will be more precise and more robust than the normal Point Tracker.

Using IntelliTrack: All the IntelliTrack analysis happens behind the scenes, and there is no additional user input required other than to choose the IntelliTrack setting, set the tracking crosshairs over high contrast areas on the same moving subject, and then press one of the tracker direction controls.

Cloud Tracker Workflows

The next few examples illustrate how to use the Tracker palette's controls in practical situations. In many circumstances, objects passing in front of a tracked subject, known as "occlusions," can cause problems. While the tracker in DaVinci Resolve is highly occlusion-resistant, the following sections show a variety of techniques you can use when an occlusion prevents you from getting a useful track.

Using Interactive Mode to Manually Choose Tracking Features

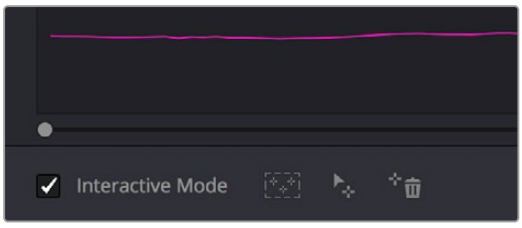
Interactive mode lets you manually remove or add tracking points to improve tracking performance in situations where the automatic image analysis in DaVinci Resolve provides unsatisfactory results.

For example, you can delete tracking points within a window that correspond to overlapping features you don't want to track. Suppose a car that you're tracking drives by a sign that partially obscures the car. Without intervention, the PowerCurve that's isolating the car will deform improperly when the car moves along and then away from the sign.

Using Interactive mode, you can delete the tracking points that will overlap the sign you don't want to track, improving the result.

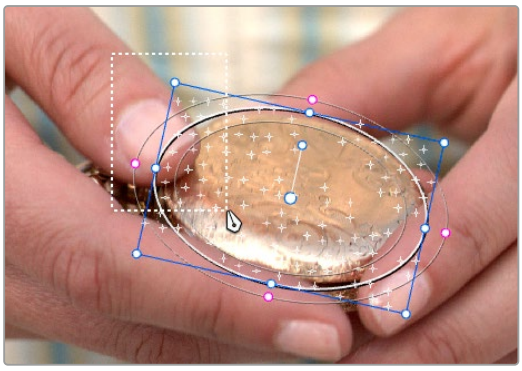
To eliminate specific, unwanted tracking points from a track:

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.



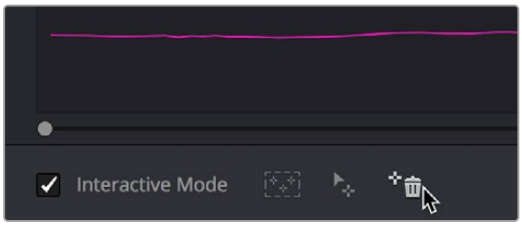
Selecting Interactive Mode

3. In the Viewer, drag a box around the tracking points you want to eliminate within the window.



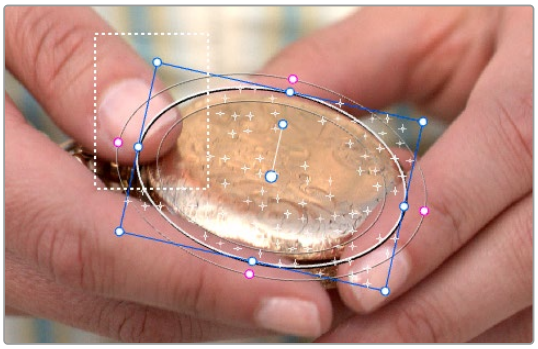
Dragging a box around tracking points that need to be deleted

4. Click the Delete button.



Deleting tracking points

The points within the selection area are deleted.



Remaining tracking points ready to be used

5 While Interactive mode is still on, click Track Forward or Track Reverse to track the subject using the remaining tracking points.

6 When you're finished tracking, turn off the Interactive Mode checkbox.

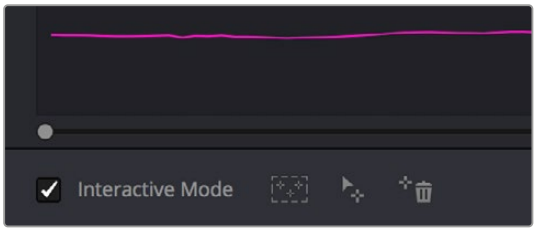
DaVinci Resolve goes back to using automatically placed tracking points.

In another interactive tracking example, you may sometimes run into situations where you want to eliminate all automatically placed tracking points altogether, placing your own in specific regions of the image.

To eliminate automatic tracking points, adding your own instead:

1 Open the Tracker palette.

2 Turn on the Interactive Mode checkbox.

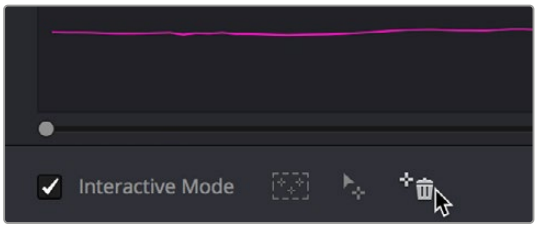


Selecting Interactive mode

3 In the Viewer, drag a box around all the tracking points in the window, and click the Delete button to eliminate all tracking points from the image.

Selection box surrounding all tracking points

4 Click the Delete button to eliminate all tracking points from the image.

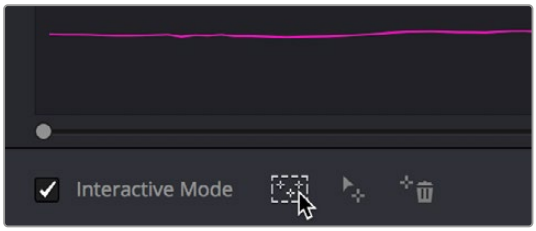


Deleting tracking points

5 Drag a box around the specific area where you'd like to add new tracking points. In this case, you only want to track the top half of the woman's face, since the bottom half is cut off by the fence posts.

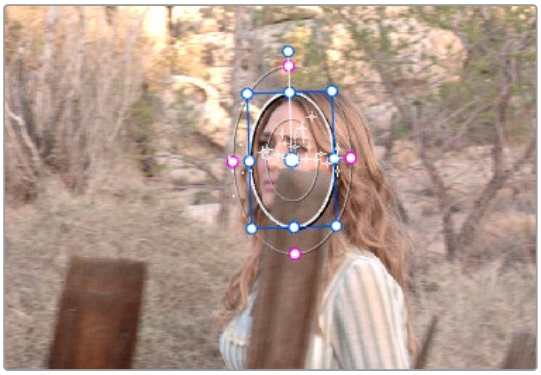
1 Placing the selection box over the top of the window

2 Now, click the Insert Track Points button.



The Insert button of Interactive mode automatically adds tracking points within the current bounding box.

New tracking points are automatically added to whichever features are appropriate for tracking within the box you've drawn.



Tracking with the remaining tracking points

NOTE: If no appropriate tracking features can be found, no points will be added.

Dealing With Occlusions When Tracking

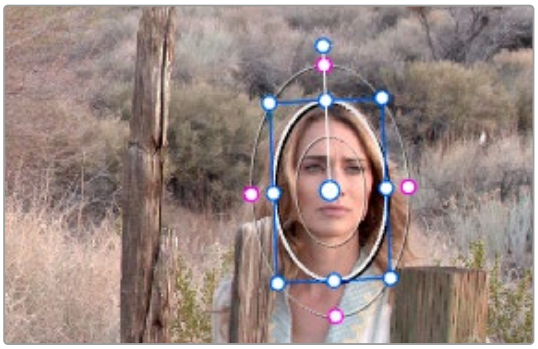
Sometimes you'll find that you need to deal with a gap in the useful tracking data. For example, objects in the frame that pass in front of the feature you're trying to track cause gaps in the tracking information for a clip.

In situations where a subject being tracked becomes totally occluded by another object in the frame, there's an easy method of interpolating to cover holes in the available tracking data. In the following example, the woman walks behind another fence post, this time one that's taller than she is. The window tracking her face will become completely lost at this point, but interpolation will help to salvage this shot.

Original clip

Interpolating between two sets of tracking data to track past an occlusion:

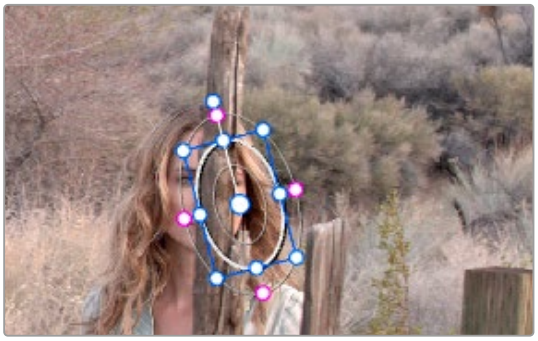
1 Move the playhead to the first trackable frame of the moving feature you're correcting, and create a Power Window that surrounds it.



Adding the Power Window

2 Use Track Forward to track the feature as far as you can before it becomes obscured behind something else in the frame.

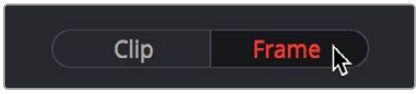
3 When the Power Window stops tracking the feature reliably, stop the track.



The Power Window is obscured by the post

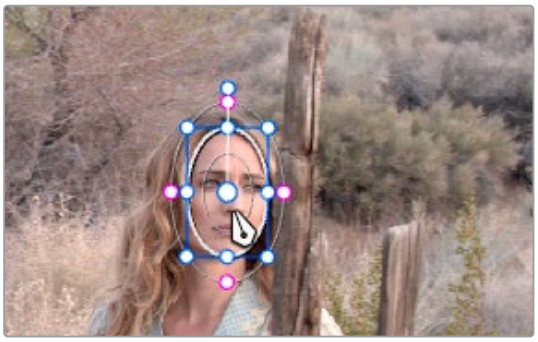
4 Open the Tracker palette.

5 Click the Frame button to put the Tracker controls into frame-by-frame adjustment mode. This is an important step.



Selecting Frame mode

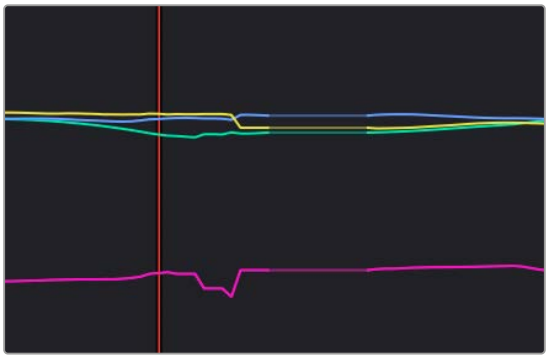
6 Move the playhead to the frame where the feature you're tracking reappears from behind the occlusion, then drag the window so that it again overlaps the feature.



Moving the playhead and position the window

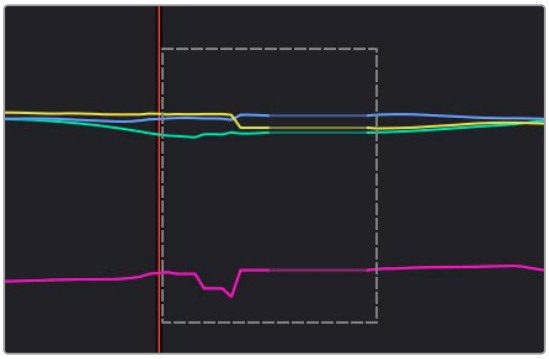
7 Use Track Forward to continue tracking the feature until the end of the clip. Alternately, you could have started from the end of the clip and used Track Reverse to track the feature as far as possible, if that's easier.

Now that you've identified the gap in reliable tracking data for this clip, it's time to set up the interpolation.

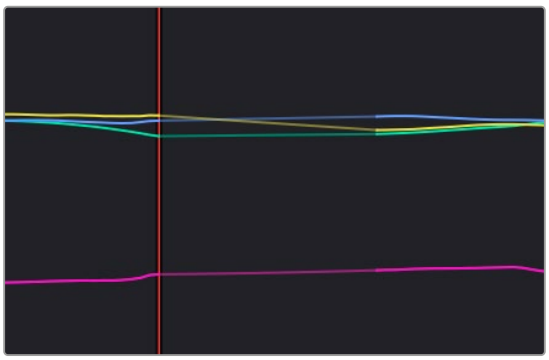


Notice the gap in the tracking data where the window was behind the post

8 Drag a bounding box over the portion of the curves in the Tracker graph that fall between the good tracking data at the beginning and end of the shot.



9 Click the Tracker palette option pop-up menu, and choose Clear Selected Track Data.



The portions of curves that you selected are deleted, and have linear interpolation automatically applied to them so that there's no hole in the track data or the motion of the window, which now moves smoothly from the last outgoing frame of reliable tracking data to the first incoming frame of new reliable tracking data.

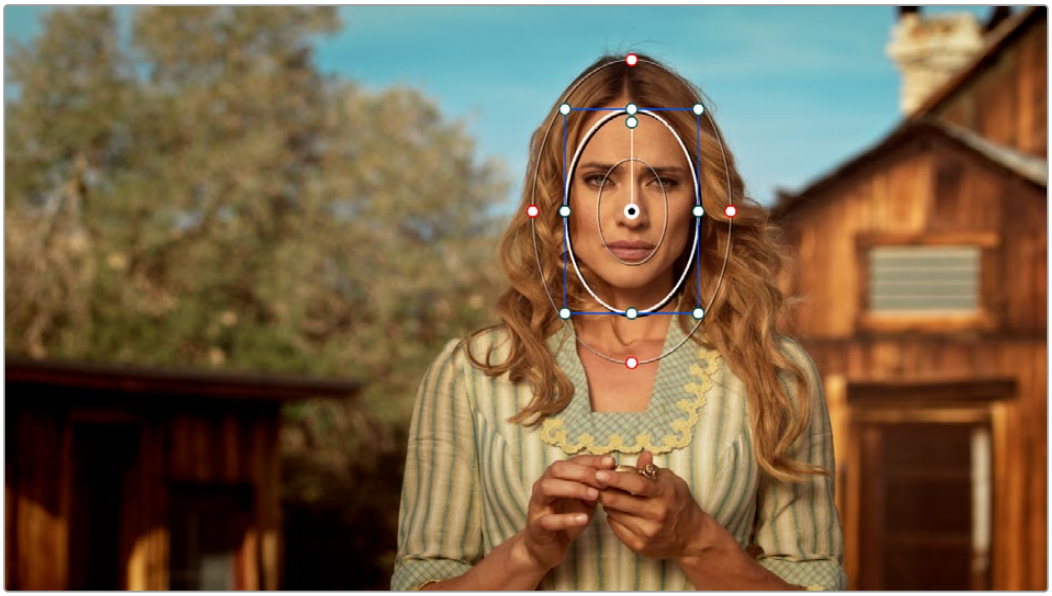
Point Tracker Workflows

As advanced as the Cloud Tracking that is the default in DaVinci Resolve is, there are times when it may be simpler to track using good old-fashioned crosshairs. The Point Tracker makes it easy to track very specific features of a subject with motion you need to follow. Unlike the Cloud Tracker, which automatically looks for all trackable points within a region of the image that you identify using a window, the Point Tracker lets you create one or more crosshairs that you must manually position to overlap with whatever high-contrast features you want to track. This section covers the three main workflows you need to know to use the Point Tracker.

Tracking a Window Using the Point Tracker

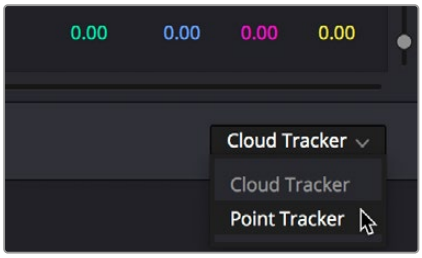
The following procedure describes, in a general way, how to use the Point Tracker to track a moving subject and apply that motion to a Power Window.

1. Move the playhead to the frame of the current shot where you want to begin (you don't have to start tracking at the first frame of a shot, since you can always track backward).
2. Turn on any window, and adjust it to surround the feature you want to track. Typically, you'll have done this anyway, for example, framing someone's moving face with a Circular window to lighten their highlights. You want to make sure that the window you want to apply the tracked motion to is selected before you begin tracking. In this example, we'll be tracking a Circular window to follow the woman's face.



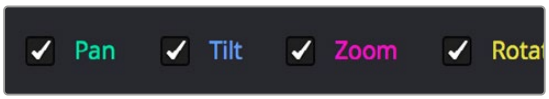
Setting up to track a window over a woman's face

3. Open the Tracker palette, and choose Point Tracker from the bottom right pop-up.



Choosing the Point Tracker

4 Before you start tracking, choose what types of motion you want to track and apply to the window you're working on. You can choose from among Pan, Tilt, Zoom, Rotate or Perspective 3D. Which methods of transformation can be applied depend on how many points you add to track.

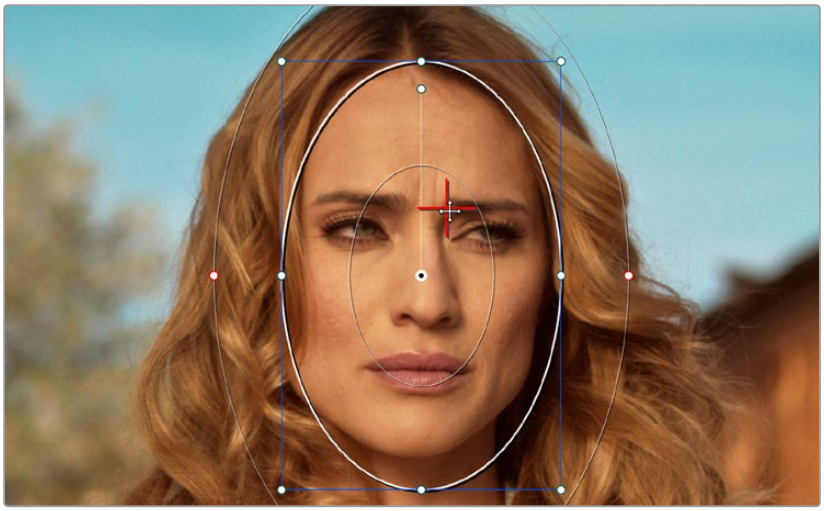


Choosing what type of motion to analyze

5 Click the Add Tracker Point icon. A new tracker crosshairs appears in the Viewer in the center of the frame.

Clicking the
Add Tracker Point icon

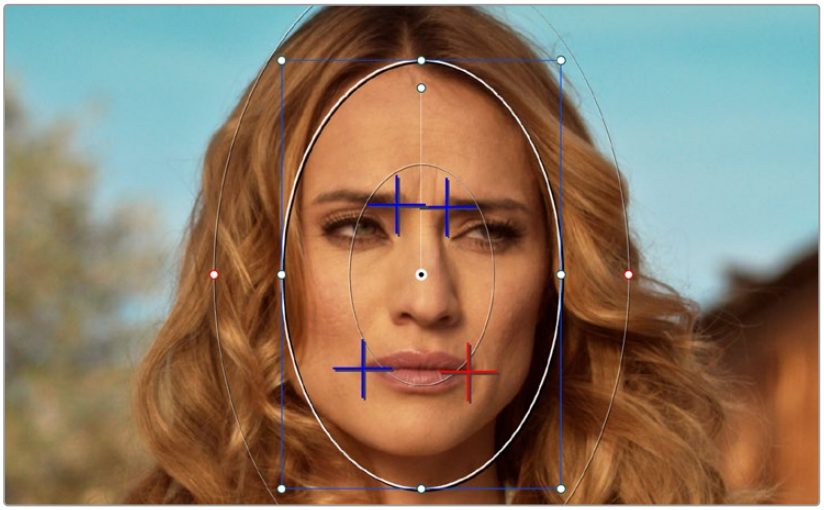
6 Move the pointer directly over the tracker crosshairs, and when it turns into the move cursor, click and drag to move the crosshairs to line up on top of the feature you want to track. For the best results, this should be a high-contrast detail such as a corner, the end of a line, a small shape like a pebble, or a jagged detail. Unlike other point trackers, there is no inside or outside region to separately adjust, there's only the one crosshairs that you need to align. In this example, this first crosshairs is placed at the inside of her stage left eyebrow (the corner of her eye would introduce too much jitter as the tracker will pick up her blinks).



Lining up the tracker crosshairs with the feature you need to track

7 If you want to improve the accuracy of your track, you can create more tracker crosshairs and position them on top of other details within the subject you're tracking. For the best results, make sure that all crosshairs are placed onto details that are in the same plane of motion. In other words, don't put some crosshairs on a person's face in the foreground, and other crosshairs on a tree that's far in the background, since both these features will have very different vectors of motion.

In this example, trackers are placed at her inside eyebrows and at the corner of her lips.



Setting up four trackers to follow the corners of her eyebrows and mouth

The final track, accomplished with four point trackers,
with the track path turned on

8 When you're done placing crosshairs, click the Track Forward or Track Backward buttons to initiate tracking. The clip will be analyzed, and the Tracker graph will update with the tracking data, and the window you had selected automatically moves to match the motion of the feature you're tracking.

Removing Trackers

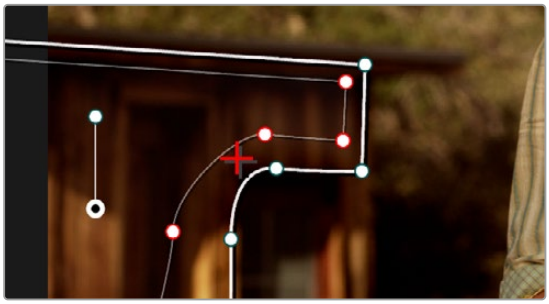
If you find that a particular tracker is causing problems, you can remove it by selecting it in the Viewer, and clicking the Delete Tracker icon, before retracking the subject.

Clicking the Delete Tracker icon

Using Frame Mode to Offset Track

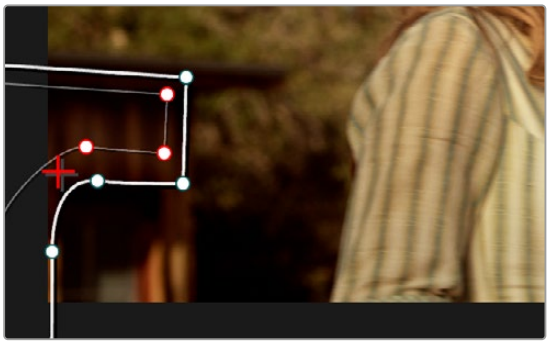
A common issue when point tracking is how to deal with occlusions and times when the tracked feature moves off screen. In DaVinci Resolve, the solution is to use the Tracker palette's Frame mode to move the tracker crosshairs onto another feature to track, while offsetting the resulting motion so that it continues to follow the original motion path.

1 In this example, a point tracker crosshairs has been positioned at a corner of a window of a building that's being separately adjusted using a Power Window. The window is being used because, as the woman turns to leave, she covers up most of the other trackable outer edges of the building, which would ruin the track.



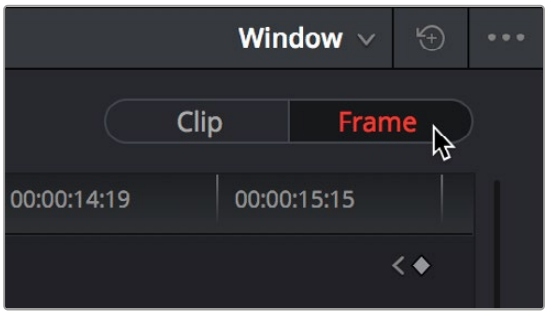
Setting up to track a building moving off screen

2 As the camera pans, the feature being tracked is about to go off frame, which is about to ruin the track. As this happens, click the Stop Track button.



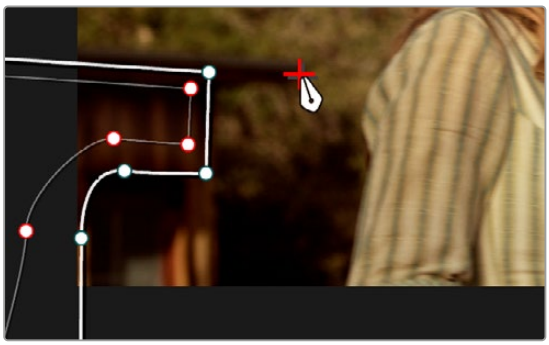
Stopping the track on the last good frame of the track, before the tracker goes off screen

3 Move the playhead back to the last good frame of tracking, and then click the Frame button in the Tracker palette to go into Frame mode.



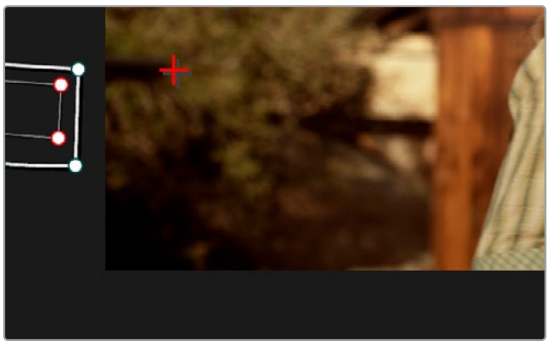
Turning on Frame mode, to prepare to offset the track

4 In Frame mode, you can now drag the tracker to another feature of the building, this time the outer edge of the roof, that will be better to follow as the building goes out of frame to the left, since the Power Window will go out of frame before the rightmost corner of the building's roof does.

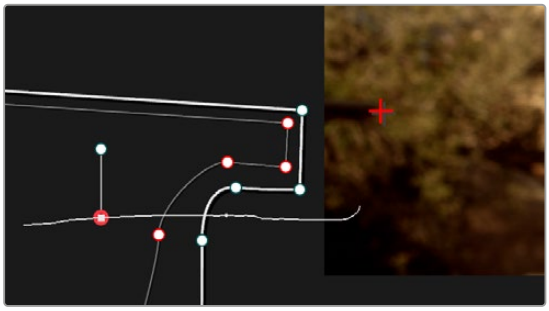


Dragging the tracker to another feature that's better to track

5 Now, click the Track Forward button again, and the crosshairs will begin tracking the new feature, but the motion will be offset, so the movement of the Power Window continues to follow the original motion path.



Tracking an offset feature lets the window go all the way off screen



The tracker path before and after moving the tracker crosshairs in Frame mode is smooth and continuous

6 If you turn on the track path (in the Tracker Option menu), and move the playhead to the frame where you moved the tracker, you can see that the motion before you moved the tracker and the motion after continues smoothly along the same path, with no sudden breaks. When you're finished, click the Clip button to get out of Frame mode.

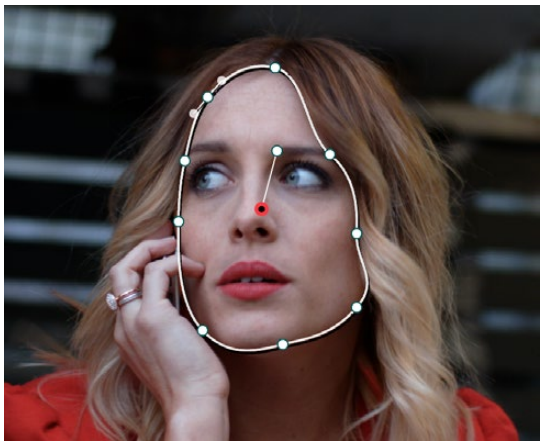
Rotoscoping Window Shapes After Tracking

While the DaVinci Resolve trackers are pretty miraculous when it comes to making a window follow moving subjects, or elements within a moving scene, there will be plenty of times when the final track isn't quite perfect.

For example, if you're trying to isolate someone's face with a very specific window, and the person turns their head, then the resulting change of shape is almost certainly going to require you to make animated adjustments to the window in order to continue making such a specific isolation.

Before and after a window tracking a turning head, the window doesn't quite follow the edge of the woman's face as her head turns

Fortunately, the Tracker palette's Frame mode makes it easy to animate shape changes you make to windows in order to better follow a moving subject, a task often referred to as rotoscoping. By following the motion of a moving subject, and making a series of automatically keyframed adjustments to the window at every point the subject changes speed or direction, you can make a window isolate a moving target with surprising precision.



Using Frame mode to rotoscope the window to better follow the edges of her face and the contours of the jaw

Furthermore, you can also use Frame mode to repair imprecise tracks where the window is veering off course because of quickly or irregularly moving features. In these cases, you have the option of manually tracking the window in Frame mode to fit the trajectory of the feature, frame by frame.

Lastly, you don't even have to have performed a track to use the Tracker graph in Frame mode to keyframe animated changes to a window. In fact, using the Tracker graph in Frame mode can sometimes be more convenient than using the Keyframe Editor in Auto Keyframe mode, depending on what you're doing.

Rotoscoping Controls

The Clip/Frame buttons determine whether or not you're rotoscoping a shape.

- **In Clip mode:** Any changes you make to a window transform it over the entire duration of that clip. In other words, you can track a window to a moving feature, and in Clip mode any changes you make to the size, rotation, position, or shape of the window occur equally from the beginning to the end of that clip.
- **In Frame mode:** Changes you make to a window automatically create a keyframe at the bottom of the ruler in the Tracker graph. Making two or more changes to a window in Frame mode results in automatically interpolated animation from one keyframed window transformation to the next.

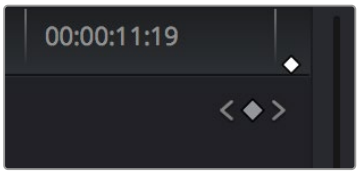
You can freely move back and forth between Clip to Frame modes to make changes to a window. Even if you've keyframed a window to change shape, you can turn on Clip mode and make an overall change to the window, enlarging it for example, that results in the window being equally enlarged at every keyframe.

Keyframing in Frame Mode

Once you've added keyframes to the Tracker palette, there are a number of ways you can edit them.

Methods of working with keyframes in the Tracker graph:

- **To add a keyframe:** Click the Add Keyframe icon at the upper right-hand corner of the Tracker graph. It looks similar to the Keyframe icons found in the Edit page Inspector. This is useful for adding a keyframe to a frame where the window fits the subject well, prior to moving forward a few frames and making an alteration to the window to follow the subject that will generate another keyframe.
- **To move the playhead from one keyframe to another:** Click the Previous Keyframe and Next Keyframe icons at the upper right-hand corner of the Tracker graph. These controls look similar to those found in the Edit page Inspector.
- **To delete a keyframe:** With the playhead on the same frame as the keyframe you want to delete, open the Tracker option menu, and choose Delete Keyframe.



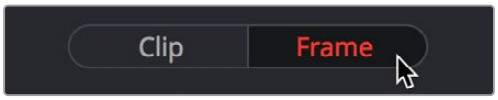
The Previous Keyframe, New Keyframe, and Next Keyframe buttons in the Tracker graph

A Rotoscoping Workflow

The following procedure demonstrates how to use a window to rotoscope an onscreen feature that you want to isolate. In the process, it shows how to set up a window for rotoscoping using the Tracker palette, and discusses some best practices for rotoscoping efficiently.

To rotoscope or manually track a window using automatic keyframing:

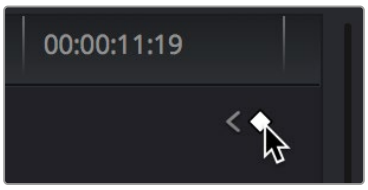
1. Create a window to isolate the feature you're wanting to adjust, and use the tracker to make it follow the motion of the subject. If the window doesn't follow the contours of the subject as precisely as you require, then you can begin manually keyframing its shape on top of the tracking you've done to rotoscope the subject.
2. With the Tracker palette open, click Frame to change the tracking mode.



Clicking the Frame button to begin keyframing your shape

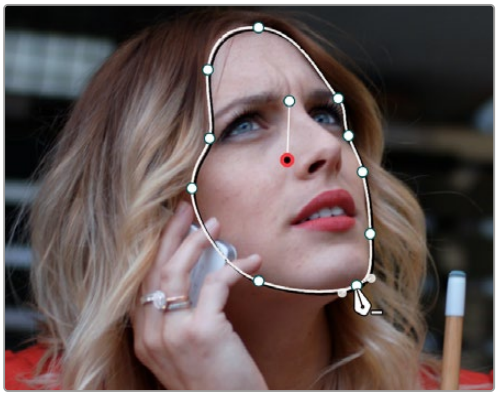
The best way to use Frame mode for tracking is to either start at the last successfully tracked frame and work your way forward, or start at the first successfully tracked frame and work your way backward. This takes the best advantage of the automatic keyframing and interpolation between keyframes to animate the window you're transforming smoothly.

3 With the playhead at either the first or last frame where the window fits the subject you're isolating, you can either click the Add Keyframe button at the upper right-hand corner of the Tracker graph, or wiggle any control point by a pixel or two, to add a keyframe at that frame.



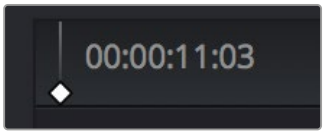
Clicking the Add Keyframe icon in the Tracker graph

Adding a keyframe at the last frame where the window follows the subject's motion well means that any future animated changes you make interpolate from this frame forward, rather than from previous frames where there's no need for alterations.



Adjusting the window in Frame mode adds a keyframe

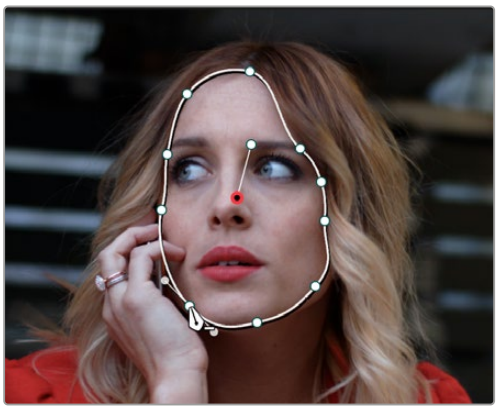
While you're in Frame mode, the changes you make to the window automatically generate a keyframe in the Tracker palette, which appears at the bottom of the Tracker graph's timeline.



Keyframes appear in the Tracker graph ruler

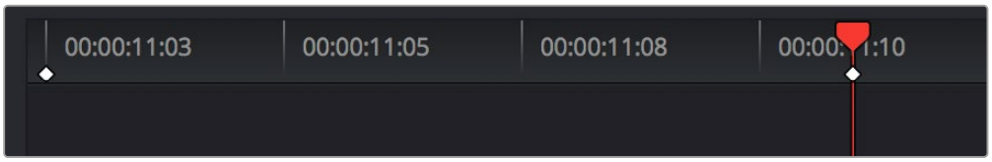
It's frequently essential to add a keyframe at the last frame where a window conforms well to the subject you're trying to isolate, in order to limit window animation from that frame to the next keyframed transformation, rather than accidentally animating from the beginning of the clip, or from the next or previous keyframe in the Tracker graph.

4 Next, move the playhead to the next frame where the window requires adjustment to better fit the moving subject, and adjust the position of the window, the control points of the window, or both to isolate the subject as necessary.



Readjusting the window in Frame mode to follow the subject's motion

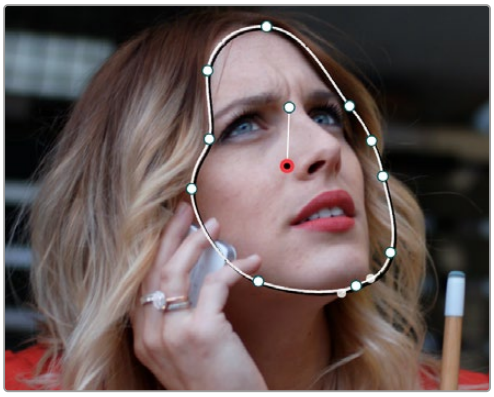
This results in a second keyframe being placed in the ruler of the Tracker graph.



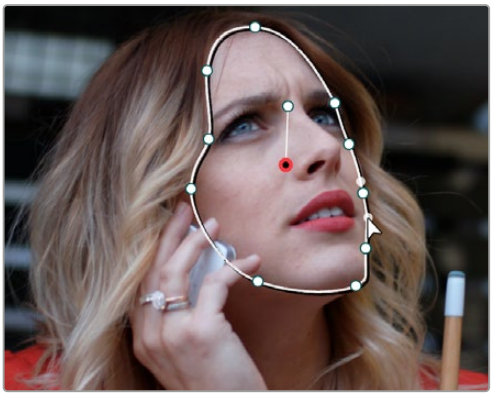
Two keyframes creating rotoscoped animation in addition to any motion tracking that's applied

5 With your first two keyframes placed, scrub the playhead back and forth between them to evaluate how well the window's animation is automatically interpolating to fit the motion of the subject you're isolating. If the window doesn't follow the motion of your subject well enough, move the playhead to the frame where the window divergence is the most pronounced and make another adjustment to correct the shape.

This creates another keyframe.



A frame between the two keyframes you've rotoscoped that needs further adjustment



After adjusting the in-between frame

6 When you're finished making adjustments between your first two keyframes, move the playhead farther along and add keyframes as necessary to make the window follow the motion of your subject.

In general, look for the frames where your subject's motion starts, stops, speeds up, slows down, or changes direction. As you work, it's good to try and add the fewest number of keyframes you can to ensure smooth motion from one to another. Too many keyframed adjustments made too close together for a smoothly moving subject risks adding jerky motion if you're not careful. On the other hand, if you have an erratically moving subject, you may have to add more keyframes, possibly frame by frame, to achieve the desired result.

> **TIP:** If you're isolating a subject with a complex shape that moves quite a lot, you might consider using multiple simple overlapping shapes to track and rotoscope it, rather than a single complicated one, to make the task easier.

7 When you're finished rotoscoping the window, be sure to click the Clip button to switch back to Clip mode, so you can trim the window's shape across every keyframe you've just created, if necessary. This will also prevent you from accidentally adding more keyframes if you select other shapes.

This technique requires a bit more work then simply using the Tracker, but it'll let you quickly adjust the animation of a window to more tightly conform to a moving subject when you need an adjustment to be specific to that subject alone. You can also use this technique to reposition specific motion path points in the middle of an otherwise successful track to make them fit better, or to add keyframes to the beginning or end of a track when the subject moves offscreen but the window does not.

Viewing a Window's Motion Path

You can turn on the motion path of the window you're tracking by choosing Show Track from the Tracker Option menu.

Chapter 139

Using the Gallery

The Gallery provides a way to save, browse, and use saved still frames from different clips in a program. Each project is saved with its own individual set of stills, and each still you save consists of a DPX image of the saved frame, and the grade metadata. You can use saved stills for reference when matching one clip to another, or you can use them to copy grades to other clips, or other timelines.

There are two ways to work with the contents of the Gallery. The Color page has a small Gallery, to the left of the Viewer, that provides quick access to saved stills and grades as you work. The Gallery window, which can be opened via a button at the top right of the Gallery, provides a dedicated interface for organizing your grades, copying grades and memories between projects, and for accessing a dedicated collection of DaVinci Resolve looks.

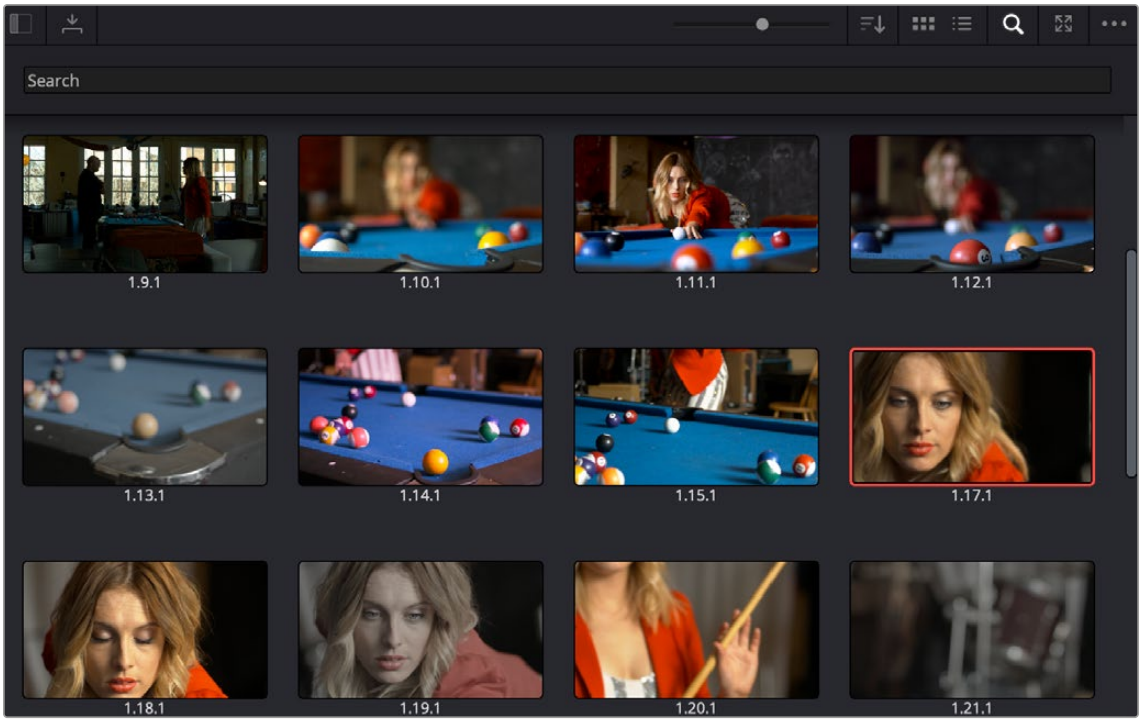
Using the Gallery

The Gallery in the Color page and the expanded Gallery window environment share many of the same commands for organizing stills. However, the commands for saving stills and customizing split-screen views are restricted to the Color page.



Color page Gallery

Saving Stills

One of the most common operations is to save a clip as a still (with that clip's embedded grade) for future reference and use.

To save an individual still in the Color page, do one of the following:

- Choose Color > Stills > Grab Still (Option-Command-G).
- Right-click on the Viewer and choose Grab Still.
- Press GRAB STILL on the Transport panel of any of the DaVinci Resolve control panels.

It's also possible to save stills automatically for every clip in the entire Timeline. This can be useful if you're planning to export a set of grades to hand off to another colorist, or if you need to apply a series of grades manually from one project to another when ColorTrace™ won't work.

To save a still for every clip in the current timeline, right-click the Viewer, and choose one of the following:

- **Grab All Stills > From First Frame:** The first frame of each clip is saved to the Gallery.
- **Grab All Stills > From Middle Frame:** The middle frame of each clip is saved to the Gallery.
- **Grab Missing Stills > From First Frame:** Only the first frame of clips with no stills in the Gallery are saved to the Gallery.
- **Grab Missing Stills > From Middle Frame:** Only the middle frame of clips with no stills in the Gallery are saved to the Gallery.

You can cancel the Grab All Stills operation at any time by clicking on the Cancel button in the "grabbing stills" dialog box. This is useful if you notice a clip needs to be altered after starting the tool, and you don't want to wait for the operation to finish grabbing stills from the entire timeline before fixing it. Once you've made your correction, simply run Grab All Stills again.

By default, when you save one or more stills, they're named "TrackNumber.ShotNumber.VersionNumber" with dots separating each number. If you like, you can choose an option from the General Options panel of the Project Settings to "Automatically label Gallery stills" in different ways. This is covered in more detail later in this chapter.

Selecting Stills

To select a range of stills, do one of the following:

- Click one still, then Shift-click another to select a contiguous range of stills.
- Command-click any stills you like to make a noncontiguous selection.
- Right-click any still, and choose one of the following commands;

  Select All: Selects every clip in the Gallery.

  Select Current to Last: Selects every still from the one you've clicked through the last still in the Gallery.

  Select First to Current: Selects every still from the one you've clicked through the first still in the Gallery.

Deleting Stills

If you need to remove one or more stills, this can only be done using the Gallery's contextual menu.

To delete one or more stills, do one of the following:

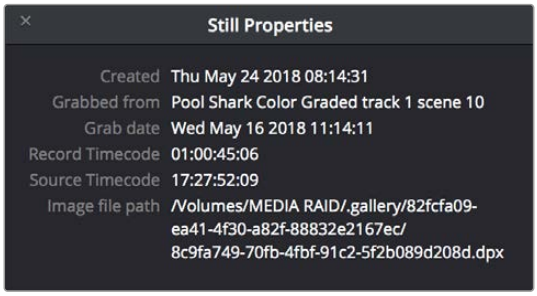
1. Select one or more stills in the Gallery.
2. Right-click one of the selected stills and choose Delete Selected.

   Each still is also saved with a variety of metadata that is used by DaVinci Resolve to manage the contents of the Gallery in different ways. This metadata can also be used for searching and sorting, and is viewable by opening the Still Properties window.

To display a still's properties:

- Right-click a still in the Gallery and choose Properties.

  A floating translucent window appears displaying the date the still was created, what clip it was grabbed from, when it was grabbed, and the source and record timecode values of the frame it came from.



Right-click on a still to choose Still Properties

Where are Stills Saved?

By default, all grades/stills you save are saved in the DPX format, and are placed in the directory path defined in the “Gallery stills location” field in the Working Folders section of the Master Settings panel of the Project Settings. This path defaults to a hidden “.gallery” directory that’s created at the location of the first Media Storage Volume you specify in the Media Storage panel of the System Preferences window.

Changing the PowerGrade Still Directory

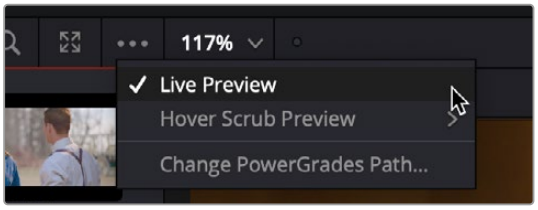
Optionally, you can change the location where PowerGrade stills are saved by Opening the Gallery Option menu and choosing Change PowerGrades Path. You’ll be prompted via a “Select PowerGrades Folder” dialog to choose a directory where all PowerGrades will be saved.

Live Previews of Gallery Stills

The Live Preview option, found in the Gallery option menu, lets you preview how the current clip would look with a particular Gallery Still grade applied to the currently selected clip simply by moving the pointer over the still you want to preview.

Enabling and Disabling the Gallery Live Preview:

1 Open the Gallery option menu and choose Live Preview.



The Live Preview option for the Gallery browser lets you hover over a saved grade to preview it on the current clip in the Viewer

2 Click a node in the Node Editor you want to preview applying the grade from a still to. The live preview will display how the current clip will appear with the grade of the still you select applied to the currently selected node of current grade, which will affect the result.

3 Move the pointer over the still you want to preview.

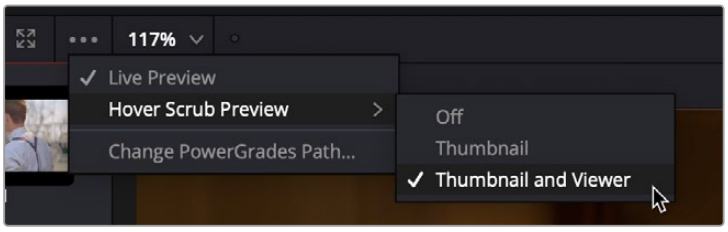
The Viewer image updates to show how that clip would look with that still’s grade applied to the currently selected node.

Hover Scrub in the Gallery

When Live Preview is enabled in the Gallery option menu, the Hover Scrub Preview submenu lets you choose how you want Live Preview to be shown by a thumbnail in the Gallery and in the Viewer when you hover the pointer over a still or LUT in the LUT Browser:

- You can choose to scrub both the thumbnail you’re hovering over and the Viewer, letting you preview the current still’s grade or a LUT over the duration of the current clip in both the thumbnail and Viewer.
- You can choose to scrub just the thumbnail, leaving the Viewer to show just the grade or LUT over the frame at the position of the playhead.

- You can disable scrubbing altogether, in which case both the thumbnail and the Viewer will only show the grade or LUT over the frame at the position of the playhead.



The Hover Scrub Preview options when Live Preview is enabled

Playing Stills and Setting Up Image Wipes

There are many ways to play a still in the Color page, making it visible as an image wipe in the Viewer and on the external display connected to your video interface.

To play a still, displaying it as an image wipe or full screen, do one of the following:

- Double-click a still in the Gallery.
- Select a still in the Gallery, and click the Image Wipe button on the top Viewer toolbar.
- Click a still in the Gallery, then right-click in the Viewer and choose Show Reference Wipe.
- From the Color > Stills menu, choose Next Still (Option-Command-N) or Previous Still (Option-Command-B) to select a still in the Gallery, and then choose Wipe On/Off (Command-W) to play it.
- Press PREV STILL or NEXT STILL on the DaVinci Resolve Advanced Search Dial panel, or the DaVinci Resolve Advanced control panel to select a still, then press PLAY STILL. Press PLAY STILL again to dismiss the still.

Whenever you play a still, the Viewer mode's drop-down menu changes to Split mode.

Once displayed, the wipe between the current clip and the still being referenced can be moved and reoriented in different ways. If you want a full-screen view so you can flip back and forth between the still and the current clip, simply adjust the split until the still fills the entire Viewer.

To adjust a wipe in the Viewer, do one of the following:

- Drag the pointer within the Color page's Viewer to move the wipe.
- Push the T-bar lever up and down on the T-bar panel of the DaVinci Resolve Advanced control panel.

To customize the type of image wipe that's displayed in the Viewer, do one of the following:

- Click any of the controls at the top right of the Viewer toolbar to choose Horizontal, Vertical, Mix, Alpha, Box, and Difference types of wipe.
- Choose Gallery, Timeline, or Offline from the Reference Wipe Mode submenu in the Viewer's option menu.
- Choose Horizontal, Vertical, Mix, Alpha, Difference, and Box from either the Wipe Style submenu in the Viewer's option menu, or the style icons at the top of the Viewer.
- Choose Invert Wipe (Option-W) from the Viewer's option menu.

Timeline Wipes

A timeline wipe is when you use the Wipe Timeline Clip command in the Thumbnail timeline (it's found in the contextual menu when you right-click a clip other than the current clip) to wipe the current clip against another clip in the Timeline, without needing to save a still first. When you turn a timeline wipe on, the clip in the timeline that's being wiped is outlined in blue.

Gang Timeline Wipe With Current Clip

A "Gang timeline wipe with current clip" option, available from the Viewer option menu, lets you maintain the offset between the current clip and a timeline clip you're wiping against when you move the current clip selection to other clips. With this option enabled, the offset between the timeline wiped clip and the current clip is maintained when you move the clip selection. When this option is disabled, the timeline wiped clip stays where it is regardless of what clip you select.

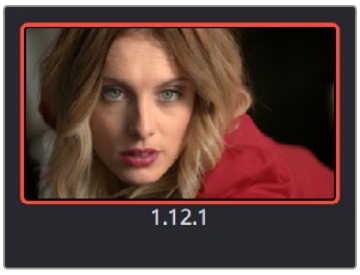
Change a Timeline Wipe Using the Timelines Album of the Gallery

While you're using the Wipe Timeline Clip to show a wipe of the current clip against any other clip in the Timeline, you can open the Timelines album of the Gallery and click different clips to change which Timeline clip you're wiping against (outlined in blue) without changing the current clip (outlined in orange). Make sure you have selected the same timeline in both the Timeline album, and the Color page.

Labeling and Searching for Stills and Sources

By default, all stills are identified by a three-number code. The first number is the video track the clip is on, the second number is the clip's position number in the current Timeline, and the third number is the version number of the grade.

If you've saved many stills, it can help to label the important ones with whatever text you find helpful. Once labeled, you can search for stills by label using the Search field, at the upper right-hand corner of the Gallery.



All stills are numbered Track.Shot.Version

Automatic Labeling

If you like, you can choose an option from the Color group in the General Options panel of the Project Settings to “Automatically label Gallery stills” in different ways. There are many options:

- **Clip Name:** Saves the Clip Name, which defaults to the File Name unless you’ve customized it.
- **Clip Version Name:** Automatically saves the name of the current version.
- **Source timecode (HH.MM.SS.FF):** Saves the source timecode of the current frame.
- **Timeline timecode (HH.MM.SS.FF):** Saves the timecode for the playhead’s position in the Timeline.
- **Timeline Name:** Saves the name of the currently open Timeline.
- **Display LUT Name:** Saves the name of the currently used Display LUT, if one is applied.
- **Custom label using tags:** Choosing this option reveals a field you can use to either type custom text into, or in which you can use metadata variables to save automatically updated information relating to the currently selected clip and timeline. For more information about using metadata variables, *see Chapter 16, “Using Variables and Keywords.”*

For all options, there’s also a checkbox you can toggle:

- **Append still number on export:** Turning this checkbox on lets you choose how to include the default still number when exporting stills with the “Use labels on export” option enabled, either as a prefix or suffix.

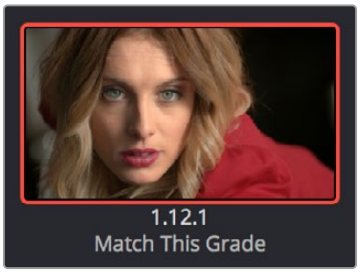
Manual Labeling

Sometimes the easiest thing to do is to just give a particular still a custom name that’s representative of what that still represents, such as “SeemedLikeAGoodIdea.” When naming stills manually, it’s best to avoid using the forward slash character in case you find yourself exporting these stills with file names. In fact, it’s a good idea to avoid using the forward slash character for just about any text that you add in DaVinci Resolve.

To manually label a still:

1. Right-click a still in the Gallery and choose Change Label or double-click directly under the Still ID.
2. Type a name into the Change Still Label dialog, and click OK.

   The new label appears underneath the still number.



You can also label stills for easier identification

Searching For Stills

Once labeled, you can search for stills you need in the Gallery.

To search for a still by label:

- Click the Magnifying Glass button to open the Search field, click to place the cursor within, and then type the name or description you are searching for.

  As soon as you start typing, DaVinci Resolve automatically begins to filter the results of the currently selected album in the Gallery to match what's been typed.

Match Reference Wipe Frame

You can right-click any Gallery still and choose Match Reference Wipe Frame to automatically move the playhead to the exact frame that corresponds to that still, and select that clip in the Color page Timeline.

Gallery Options

In the upper right corner of the Gallery palette there are several options that let you adjust the view and organization of your stills.

- **Still Size Slider:** Dragging this slider to the left makes the still thumbnails smaller, dragging it to the right makes them larger.
- **Sort Stills:** Choosing an option from this submenu changes the sort order of all clips in the Gallery. The options are:

  Still ID: Sorts all stills by their assigned ID number (track, clip number, grade version).

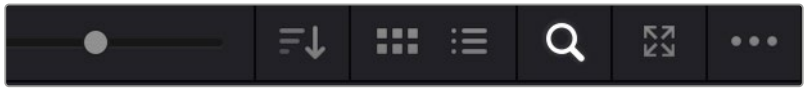
  Label: Sorts all stills by their text label.

  Record Timecode: Sorts all stills by their position in the program.

  Source Timecode: Sorts all stills by the timecode of the source clip they came from.

  Grab Date: Sorts all stills by the date they were originally grabbed.

  Create Time: Sorts stills based on when you saved each still.
- **Thumbnail View:** Pressing this icon puts the gallery in Thumbnail view; each still is represented by an image.
- **List View:** Pressing this icon puts the gallery in List view; each still is represented by columns of text attributes.
- **Search:** Opens up a search dialog box, to find stills based on their text label.
- **Gallery View:** Opens up the full Gallery Management window.



The Gallery options (L-R): Still Size Slider, Sort Stills, Thumbnail, List, Search, Expand, Options

When you right-click the gray area of the Gallery, behind the Still icons, you can open a contextual menu that provides a variety of additional options for controlling how many stills are saved, how they're displayed, and how they're arranged in the Gallery. There are the following options:

- **Switch Wipe Mode:** Switches the Reference mode between showing a "Gallery" still, a "Timeline" clip, or an "Offline" reference movie.
- **Trace Timeline:** When enabled, selecting a clip in the Timeline also automatically selects the first still that was saved from that clip to the Gallery.
- **One Still Per Scene:** When enabled, restricts the Gallery to save only a single still for each clip in the Timeline. If multiple stills have already been saved before turning this option on, those stills will remain in the Gallery until you save another still from the same clip, at which time all other stills from that clip will disappear.
- **Apply Display LUT:** If you have a Display LUT selected in the Lookup Tables panel of the Color Management panel of the Project Settings, it's applied to the video output via a connected video interface, and also to the Viewer. Ordinarily, you don't also want the Display LUT applied to stills you're saving since it's meant to be temporary. Accordingly, stills are saved with a LUT-free image. However, in instances where you may also want to save a reference to the currently used Display LUT, turning on "Apply Display LUT" saves the Display LUT along with the still, and applies that LUT when that still is used for split-screen reference. Keep in mind that the internally saved Display LUT is only used when playing that still in the Viewer; the DPX image that's saved remains unaffected.
- **Apply Grades Using:** This submenu contains three options for how to apply the keyframes that are automatically saved within each saved grade.

  No Keyframes: No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.

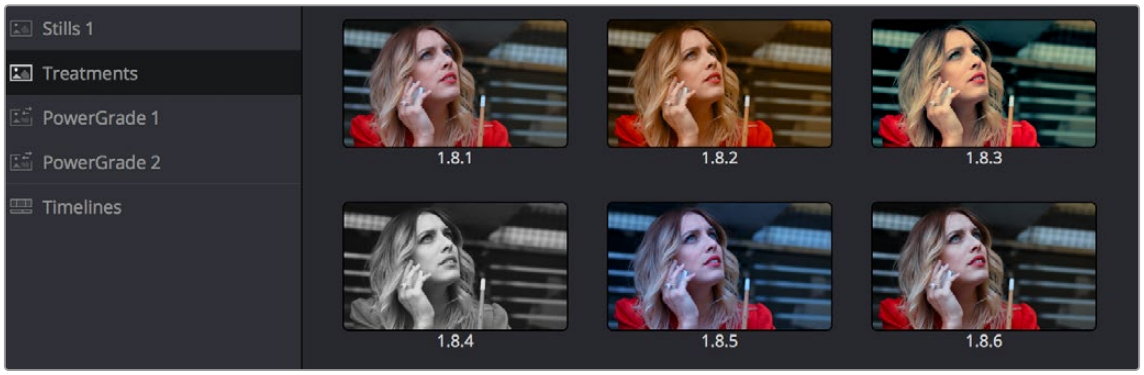
  Keyframes Aligning Source Timecode: Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you're copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).

  Keyframes Aligning Start Frames: Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you're copying a grade with keyframes from one clip to a completely different clip, with different timecode.
- **Use labels on still export:** Lets you use labels that you've added to stills in the file name of exported stills.
- **Show All Stills:** This command shows all available stills in the current album if any have been hidden, for example by searching or by using the Show Current Timeline Only command.
- **Show Current Timeline Only:** Choosing this option restricts the Gallery to only showing the stills that were saved from the currently selected Timeline. All other stills from other Timelines are hidden until you switch to that Timeline.

NOTE: There are a variety of other commands available in this contextual menu that are covered elsewhere in this chapter.

Organizing Stills Using Albums

All stills you save are always placed into the currently open album of the Gallery, which defaults for new projects to “Stills 1.” However, you can create additional albums with which to organize your stills into whatever categories you require. Albums can be shown, created, and removed using the Gallery in either the Color page or Gallery windows.



Use albums to organize your stills

To show or hide the Albums list:

- Click the Album button, at the top left of the Gallery.

If the Albums list was hidden, clicking the Album button will make the Albums list appear, to the left of the Gallery, containing all albums that are currently available in the project that’s open, as well as the PowerGrade album at the bottom. If the Albums list is already visible, then it becomes hidden, making more room for still thumbnails in the Gallery.

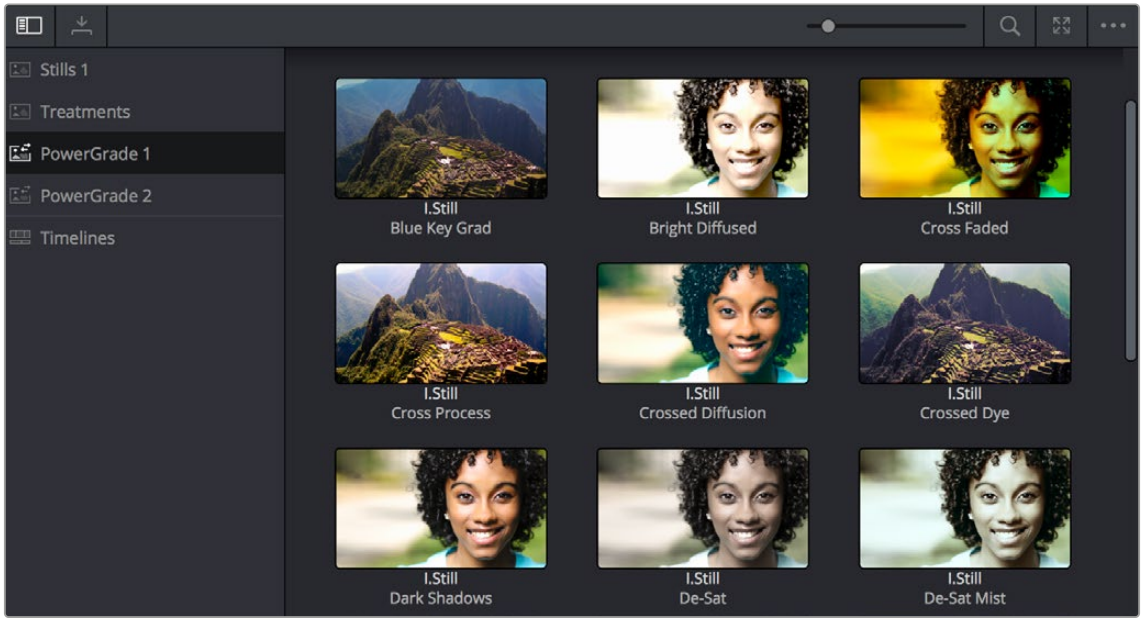
Once you’ve displayed the Albums list, there are a variety of ways you can quickly and easily work with albums.

Methods of working with albums:

- **To add a new album:** Right-click the Albums list, and choose Add Still Album from the contextual menu. A new album is created, numbered incrementally.
- **To add a new PowerGrade album:** Right-click the Albums list, and choose Add PowerGrade Album from the contextual menu. A new album is created, numbered incrementally.
- **To rename an album:** Double-click any album in the list, and when it is selected, type a new name and press Return.
- **To navigate albums:** Click any album to make it the current album. Using the DaVinci Resolve Advanced control panel, you can use the PREV PAGE/NEXT PAGE buttons to move up and down the Album list.
- **To move clips from one album to another:** Drag and drop a still from the Gallery to an album.
- **To remove an album:** Right-click any album, choose Remove Current Album, and click Delete at the prompt. All clips inside that album will be deleted along with the album, so use this carefully.

PowerGrade Albums

PowerGrade albums are meant to be repositories for grades you want to reuse frequently, or for stills that you need to reference from multiple projects, such as when grading a series that shares common looks from episode to episode.



PowerGrades are associated with your user login

Unlike stills saved to the other albums in the list, which are ordinarily available only to the project in which they were saved, stills saved to a PowerGrade album are shared among all projects that have been stored within a particular project library. Each project library has its own unique PowerGrade album.

Creating a new project library creates a new PowerGrade album, which starts out as a clean slate. However, you can always use the Gallery window to copy PowerGrade stills from other projects and project libraries to the current one, and you can create as many PowerGrade albums as you need to organize your grades.

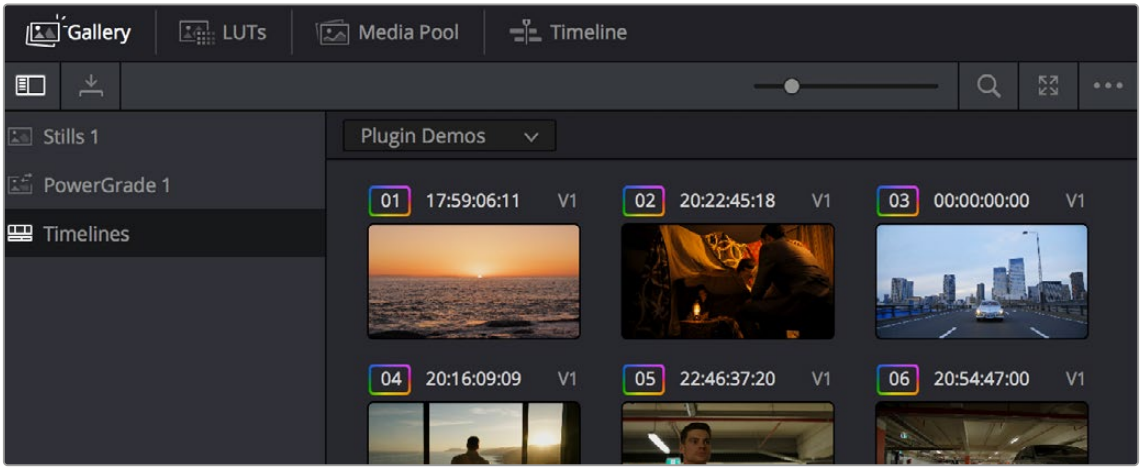
> For more information about project management and project libraries, *see Chapter 3, "Managing Projects and Project Libraries."*

Functionally, PowerGrade albums are identical to any other album, and you can save, organize, and use stills in PowerGrade albums as you would with other albums. Since PowerGrade albums are special in that they're maintained by DaVinci Resolve, the last PowerGrade album cannot be deleted.

Browse all Grades from the Current Timeline

The Gallery has a Timelines album, available at the bottom of the Album list, that lets you browse all the grades in the current timeline, or in other timelines of the current project (using a drop-down menu that appears at the top of the Gallery browser area), making it easy to copy grades from earlier or later in your timeline, or from other timelines that share the same media.

This is particularly useful for reality shows or documentaries where the same clips can appear multiple times in different parts of a program. Being able to simply show all existing grades in the Gallery frees you from having to save a still for every grade you think you might eventually reuse.



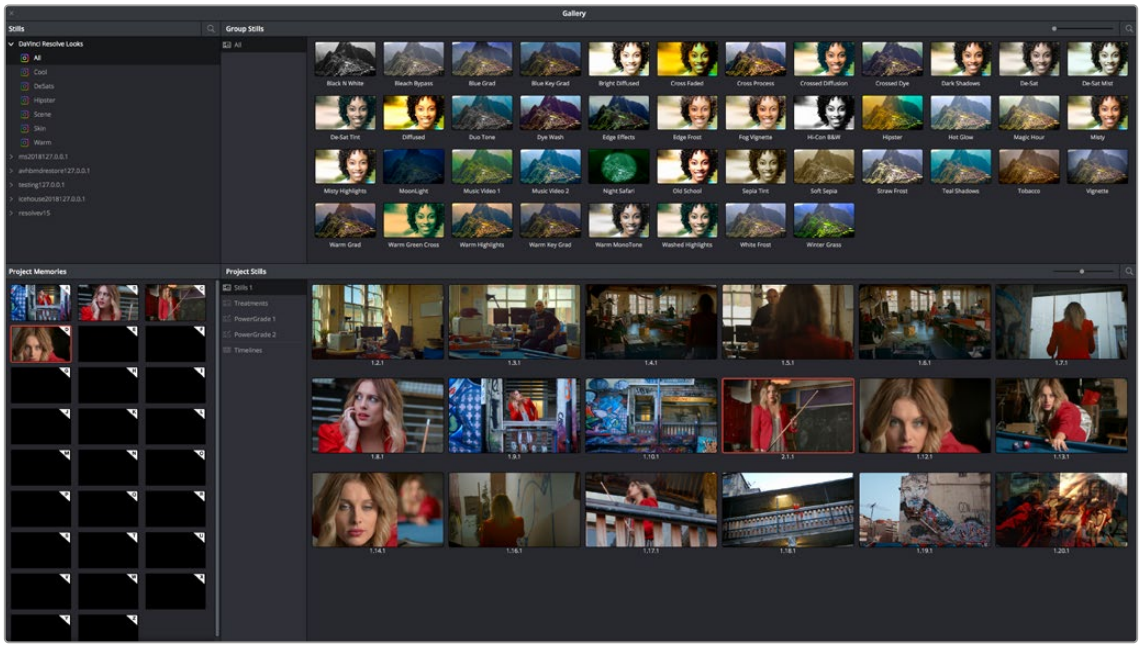
The Timelines grade browser in the Gallery automatically shows all grades in the current timeline

The Gallery Management Window

While you can do quite a lot of stills management using the Gallery as it appears in the Color page, the Gallery window provides additional functionality for copying stills among different projects and project libraries, for organizing your stills and memories, and for accessing the DaVinci Resolve looks that accompany the application.

To open the Gallery window:

- Click the Gallery View button at the upper right-hand corner of the Gallery or select Workspace > Gallery.



Gallery window

The Gallery opens into a floating window, divided into four areas:

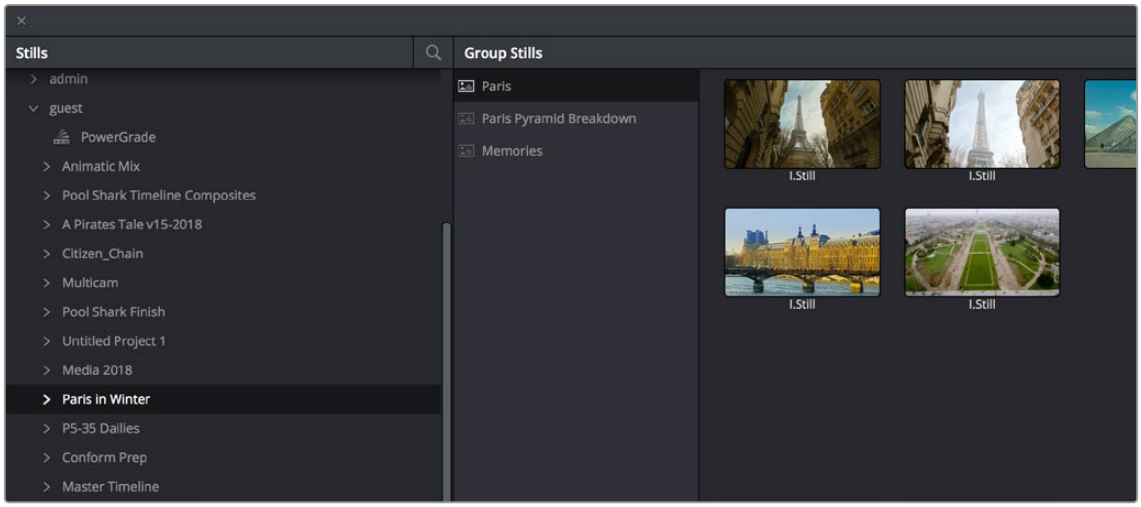
- **Stills navigator:** Lets you navigate the contents of other projects and project libraries that are available. Independent projects, as well as project library > user > project relationships, appear in this hierarchical list. Click the disclosure triangle next to any item on this list to reveal its contents. Click any project in the list to reveal its albums and stills in the Group Stills browser.
- **Group Stills browser:** Displays the contents of the currently selected item in the Stills navigator. One or more selected stills can be copied to the current project by selecting an album in the Project Stills browser, and dragging and dropping the selected stills to the Project Stills browsing area.
- **Project Stills browser:** Contains the same Album list and Project Stills browser that's visible in the Color page Gallery.
- **Project Memories:** Provides a larger view of the project memories that are visible in the Color page Gallery.

To resize different areas of the Gallery window:

- Move the pointer to the border between any areas of the Gallery. When the pointer changes to the resize cursor, drag the border to resize the adjacent interface areas to whatever size you need. Dragging all the way to the edge of the screen hides that interface area completely.

What's Available in the Stills Navigator

The Stills Navigator accesses a variety of content via a hierarchical list. Disclosure triangles to the left of each item in the Stills browser let you access the contents of each item, and many items have several nested levels of content within, each accessed by its own disclosure triangle.



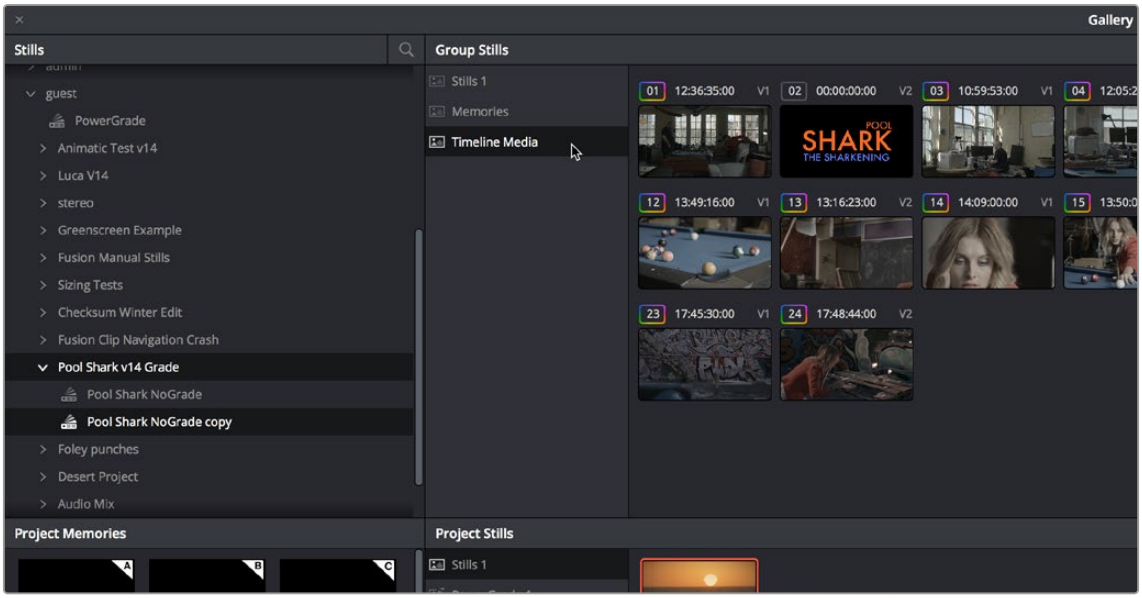
The Gallery Stills project library show all projects connected so you can import those stills

- **DaVinci Resolve looks:** A collection of predefined grades, categorized by type, that provides excellent examples of different looks available in DaVinci Resolve. These grades are installed with DaVinci Resolve and cannot be altered.
- **Project Libraries:** Each project library that's available appears within this list. Each project library has a nested series of users, projects, and timelines within, as well as one nested PowerGrade item for each user, which provides access to the saved stills within.
- **Orphans:** Stills are saved to a separate directory which is defined in the Master Settings panel of the Project Settings. Whenever you delete a project library, the stills that corresponded to that project library become orphaned. All orphaned stills that lack a connection to any current project library appear within the Orphan item in the Stills Navigator.

Browse and Import Timeline Grades From Other Projects

The Gallery window lets you see and import grades in the timelines of other projects, even if they weren't saved as stills first. When you open the Gallery Window and use the hierarchical disclosure controls of the Stills panel to open up and select a specific Project Library > User > Project > Timeline, you'll see at least three browsable albums to the right: the Stills galleries that were created, the Memories, and at the bottom an album called Timeline Media. The Timeline Media album lets you browse the currently used grades for every clip in that timeline, making it easy to copy the ones you need to the current project's Stills album or Memories.

This is particularly useful if you're working on a series where and you find that you want to re-use different grades, looks, adjustments, or fixes from previous episodes in the current one. Previously, you'd have to remember to save every clip as a still to be able to browse the grades in this way. Now you can simply browse the clips in the Timeline directly.



Browsing the timeline grades for another project in the project library

Importing and Exporting Stills

It's possible to import still images in different graphics formats into the Gallery, which can be particularly useful when a client provides reference images to which they'd like you to refer. It's also possible to export stills from the Gallery, which is good for sending a series of reference stills for approval to a remote client. In both cases, you can choose whether to import or export images with an accompanying LUT.

For both import and export, DaVinci Resolve supports the following file formats: DPX, CIN, TIFF, JPEG, PNG, PPM, BMP, and XPM.

To import one or more still images:

1. Right-click anywhere on the gray background of the Gallery.
2. Choose one of the following commands:
   - **Import:** Imports image files, along with a matching DRX file, if one is present in the selected directory.
   - **Import With Output LUT:** Imports an image and DRX file, along with a matching LUT file, if one is present in the selected directory.

3 When the Import Stills dialog appears, choose the type of files you want to import from the “Files of type” drop-down menu, then navigate to the files you want to import, select them, and click Import.

To export one or more still images:

1 If you want to export Gallery stills with labels that have been added to them, right-click anywhere in the background of the Gallery and choose “Use labels on still export” in the contextual menu so it becomes checked.

2 Select one or more stills in the Gallery.

3 Right-click one of the selected stills, and choose one of the following commands:

- **Export:** Two files are saved for each still you selected. An image file in the format of your choice, and a DRX (DaVinci Resolve eXchange) file that contains the grading metadata that was saved with that Gallery still.
- **Export With Display LUT:** If you have a Video Monitor Lookup Table specified for the current project in the Color Management panel of the Project Settings, this command will output the image as it is processed by the specified LUT. A DRX file is also output containing the grading metadata that was saved with that Gallery still.

4 When the Export Stills dialog appears, choose a file format to export to from the “Files of type” drop-down menu, then choose a location, type a name into the Save As field, and click Save.

Each of the selected stills is exported with all accompanying files. Each file uses as its prefix the name you typed into the Export Stills dialog, followed by an underscore, the still ID number of the selected still, and the three-letter file extension.

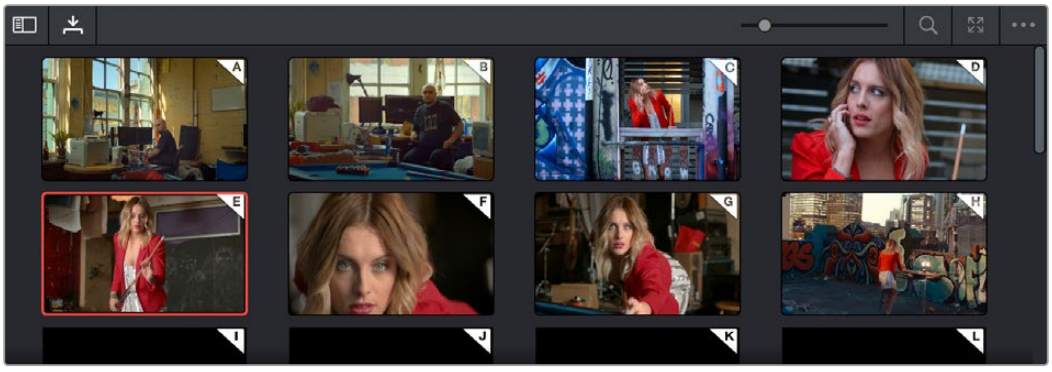
To export the grade only (.DRX file) and no image:

Normally when you export a still from the Gallery, it exports both an image file and a .drx file that contains the grade for that image. If you wish to export only the (.drx) grades from the Color Gallery, and not the associated images, you can now do this by right-clicking on a a Gallery still or stills and selecting Export from the drop-down menu. In the resulting file browser select .drx from the file format selector, and press export.

Using and Organizing Memories

Stills and memories contain identical information, and can be split screened, copied, appended, exported, and can display their node graph just like any other still. However, stills that are assigned as a memory make them easier to access via keyboard shortcuts.

Memories are hidden by default, but you can reveal them by clicking the Memories button to the right of the Gallery list button at the top-left of the Gallery.



Place grades you will use often in Memories for faster recall

The Memories thumbnail display makes it easy to keep track of which stills have been assigned to which memories in situations where you're using multiple memories to copy grades throughout a program.

To copy stills and memories back and forth, do one of the following:

- Drag a still onto a memory bank.
- Drag a memory into the Gallery.

> **TIP:** In this way, memories can be used to copy stills from one album to another.

To save the current clip's grade to a memory for future use, do one of the following:

- Choose Color > Memories > Save Memory A–H (Option-1 through 8).
- Using the DaVinci Resolve Advanced control panel, press CRNT on the Search Dial panel, then press the letter of the memory bank you want to save to. Use the SHIFT UP and SHIFT DOWN buttons to save to another memory sharing the same button.
- If you save a grade to a memory that already contains something, the previous memory is overwritten.

To apply a memory to the current clip in a timeline:

- Right-click a memory and choose Apply Grade.
- Choose Color > Memories > Load Memory A–H (Command-1–8).

To clear a memory:

- Right-click a memory, then choose Clear.

Chapter 140

Grade Management

The Color page offers numerous ways of saving grades, copying grades, creating and altering groups of clips to share grades, rippling grades and adjustments, and managing multiple versions of grades.

All of these procedures enable you to work faster by leveraging work you've already done to apply to other clips that can benefit from the same adjustments, or by applying changes across multiple clips all at once.

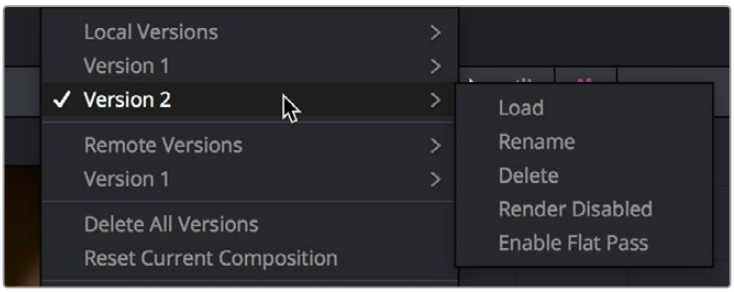
Using Versions to Manage Grades

Working quickly requires a mastery of the numerous grade management features built into DaVinci Resolve. These features are designed to help you copy and ripple grades to individual clips, among manually defined groups of clips via the Node Editor's Clip mode, or among automatically linked clips that share the same source clip in the Media Pool (when using Remote versions). Multiple versions of grades are supported for every clip, as are various options for previewing, overwriting, and appending these versions.

Choosing to Copy Grades Manually or Automatically Using Versions

Each grade you apply to a clip is a version. Each clip can have multiple versions, although only one version can be applied at a time. By default, the first grade applied to every clip in a timeline is a local version named "Version 1." A clip's version name and/or number appears underneath the clip thumbnail, to the right. You can also see the version name, along with a list of all the other versions that are currently available to that clip, by right-clicking a clip in the Timeline and looking for the version names that appear underneath the Local Versions submenu.



Selecting versions of grades from the Timeline thumbnails

NOTE: Double-clicking the version name underneath a clip's thumbnail in the Timeline cycles the version names, the clip names, and the codec used by each clip.

There are two different types of versions in DaVinci Resolve, each of which provides a different method of grade management and linking among the clips and timelines of a project.

- **Local versions:** The default mode of grade management. Clips using local versions are unlinked, so each clip has its own grade which is not shared with any other clips in any other timelines. Changing the grade of a clip using a local version has no effect on any other clip in that project.
- **Remote versions:** An alternate mode of grade management that you can enable. All clips using remote versions that share the same source clip in the Media Pool are automatically linked, in all timelines, and share the same set of grades.

If you use local versions to grade all your clips, you don't have to worry about one clip's grade being accidentally copied to other clips that happen to come from the same file in the Media Pool, which can make it easier to work. On the other hand, you need to manually copy every grade that you want to duplicate, even among clips that clearly come from the same take or angle. You can always create a group to share a grade among clips using local versions, but that's an extra step.

Switching to use remote versions, instead, puts you into a mode where clips using remote versions that share the same media file are automatically linked together. This gives you a convenient shortcut for grading your program, since a grade that's applied to one linked clip is automatically copied to every other clip it's linked to, which can be convenient when grading a series of headshots appearing throughout a program that come from the same interview take. Another use of remote versions is when you're importing a new edit of an already graded timeline. Using remote versions, you can set your project up so that new incoming timelines are automatically relinked to the previous timeline's grades.

The only disadvantage to using remote versions is that when you find you need to make individual adjustments to clips that are linked, it's an extra step to either create another version, or switch that clip to use a local version, in order to keep its adjustment separate. This will be discussed in more detail later in this chapter.

Mixing Versions

Each clip is capable of having multiple local and remote versions at the same time; you get to choose which to apply. Which type of versioning is best depends on the type of project you're working on, the way in which the media was shot, and how you like to work. The following sections explain the differences in workflow.

Using Local Versions by Default

Since local versions are the default method of grading when you first create a new project (unless you've edited your settings presets), you don't need to do anything to enable this mode at first. As the name implies, local versions are local to the Timeline in which they appear, so local versions are not rippled to linked clips, and they're not shared among different timelines. This makes it easy to avoid accidentally having grades copied when you don't want them to be, but you lose the conveniences that automatic linking can provide.

However, you can always switch the clips in a timeline to use remote versions if you change your mind, either individually, or all together.

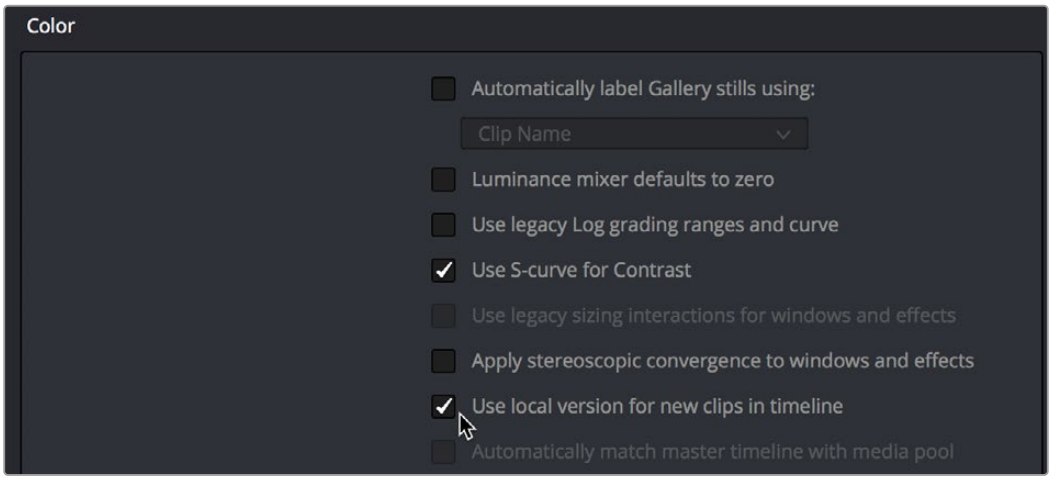
Using Remote Versions to Enable Automatic Linking

Remote versions let all clips from the same source media file in the Media Pool share their grades automatically, either within a single timeline, or across multiple timelines in the same project. However, to enable the convenience of remote grades, you need to put DaVinci Resolve into this mode of working using the Settings window.

To enable remote grades to be used:

- Open the Project Settings, open the General Options panel, and turn off "Use local version for new clips in timeline" in the Color section.

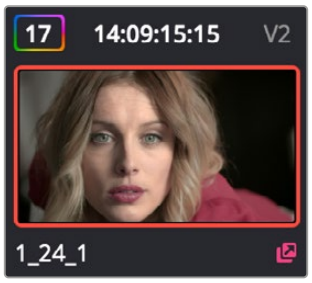
  Turning this option off only affects clips that are added to Timelines from that point onward. You can keep track of which clips use remote versions by the (R) that appears when you double-click the area underneath the thumbnail to hide the codec name in the Thumbnail timeline.



Turning off "Use local version for new clips in timeline" to enable remote grades to be used by default

How Automatic Linking Works

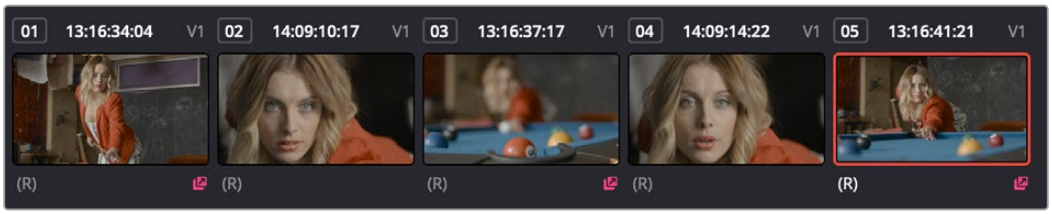
When clips using remote versions have been added to a timeline, any other clips in any timeline that (a) use remote versions also, and (b) refer to the same file in the Media Pool are linked. Selecting a clip using a remote grade in the Color page that is automatically linked to one or more clips displays a small "linked" badge at the right of that clip's timecode in the Thumbnail timeline.



The linking arrow shows this clip has the same source as the one selected on the Timeline

TIP: The Timeline Filtering drop-down in the Color Page toolbar has an option named “Common Media Pool Clips” that only shows clips in the Timeline that are linked to the currently selected clip.

Adjustments that you apply to a remote version of one linked clip are automatically rippled to every other clip it’s linked to, which can save you an enormous amount of time when you’re getting started with a new program. For example, if every reverse angle from the same take in a particular angle of coverage is automatically linked using remote versions, then the grade you apply to one reverse angle clip will ripple to every other reverse angle clip throughout the Timeline.



Timeline with three automatically linked clips shown, and codec names hidden to reveal the (R) that shows these clips are using remote grades

So long as remote versions are enabled, there are other ways that linked clip relationships are formed. If, after conforming an AAF, XML, or EDL, you used the Split Clips button in the Color page to split one conformed clip into many, each of the clips you split would be linked, since they too would share the same source media in the Media Pool.

Finally, automated linking also occurs for clips that appear in multiple timelines that also use remote versions. As a result, the grade you apply to one linked clip is automatically rippled to every other clip it’s linked to.

NOTE: Media management or media consolidation operations that split large source media files into many individual media files will defeat automatic linking within the same timeline, since each clip will be conformed to its own individual media file.

Starting with Remote Versions, Then Switching to Local Versions

It's possible to combine the best aspects of remote and local versions into a single workflow, taking advantage of your ability to freely switch from one to the other. Since remote versions make it easy to copy grades among clips that are similar, you can switch to using remote versions first, and then grade your way through the Timeline until you get to the point where you need to start making much more specific changes to individual clips. Then, it's easy to either switch each linked clip that needs individual adjustment to use a local version, or to use the Copy Remote Grades To Local command (described later) to copy the current remote version of each and every clip to a local version, at which point you can make all the specific tweaks you need to without worrying about changes being accidentally copied.

Creating a Master Timeline

DaVinci Resolve version 9 and earlier would automatically create a Master Timeline whenever you added clips to the Media Pool. This changed in versions 10 and later, which by default have no Master Timeline. However, if you want to create a Master Timeline in order to use it as you would have before, this is easy to do.

If you want a Master Timeline to have a single timeline that always contains all clips currently in the Media Pool, there's a way you can create one. However, you need to do it immediately upon creating a new project, before adding any media to the Media Pool. Once you've added one or more clips to the Media Pool, the option you need to do so will be disabled.

To create a new Master Timeline:

1. Create a new project, open the General Options panel of the Project Settings, and turn on the "Automatically match master timeline with media pool" checkbox in the Color section. If you also want all clips to use Remote versions as you grade by default as in previous versions of DaVinci Resolve, you can turn off the "Use local version for new clips in timeline" checkbox.
2. Click Save.
3. Open the Edit page, and choose File > New Timeline (Command-N).
4. When the New Timeline Properties window appears, turn the Empty Timeline checkbox off, and click Create New Timeline.

   Now, in addition to the new Timeline, a Master Timeline appears in the Timeline list.

Once created, the Master Timeline contains every clip in the Media Pool of the current project. If you color correct the clips in the Master Timeline, you'll find there's only one set of versions available, found underneath the Local submenu of the Color Page timeline's contextual menu. It's important to understand that local versions within the Master Timeline are in fact the remote versions found in every other timeline of that project.

In fact, it would be fair to say that the remote versions found in other timelines are actually the Master Timeline's versions. When you grade a clip in the Master Timeline, those grades ripple out to every other instance of that clip, in every other timeline within that project, via remote versions.

Sharing of remote versions among the Master Timeline and newly conformed timelines is why you can grade a collection of clips that you import into DaVinci Resolve without any editorial structure, grade and output offline media, and then reimport a project file that relinks to the original clips along with their grades. It's also why you can grade clips in one timeline, and then import additional re-edited timelines via AAF, XML, or EDL, which automatically inherit all remote versions of grades that were created in previous timelines.

Differentiating Clips with Individual Versions

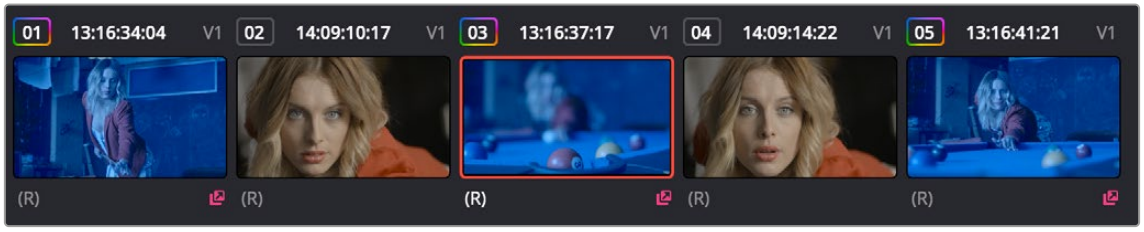
If you've enabled DaVinci Resolve to add clips with remote versions, there are times when you may want to suspend automatic linking. As convenient as automatic grade rippling among linked remote versions is, there are many instances where you may need to stop it. For example, if the Media Pool contains a source media file with the entire content of an interview, then every clip that has been conformed to that source media will be linked, which is ordinarily good since you'd expect they'd all share the same grade. However, if the DP fiddled with the exposure of the camera in the middle of the interview, such that some clips are lighter and others are darker, you may find yourself needing to make different adjustments to clips from different parts of the interview.

One way of doing this, which can be useful in timelines where you only need to make a few of these kinds of changes, is to create a new remote version for every clip to which you need to make an individual adjustment. Since each version is its own grade, and differently named versions don't link to one another, this is a simple solution.

To suspend linking by creating a new remote version:

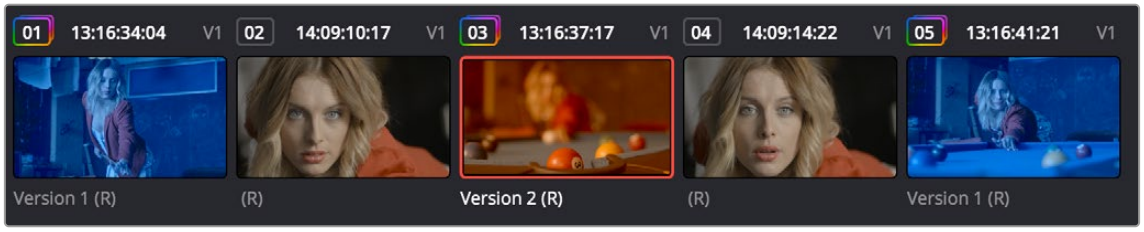
1. Move the playhead to the clip you need to alter individually.
2. Do one of the following:
   - Choose Color > Grade Version > Add (Command-Y).
   - Right-click the thumbnail in the Timeline, and choose Remote Versions > Create New Version.
3. Grade the new version that's appeared.

While this method works well, keep in mind that multiple linked clips using the same version number will always be linked with one another. In other words, suppose Clip 1, Clip 3, and Clip 5 are linked using the default Version 1, which has a strong blue grade applied.



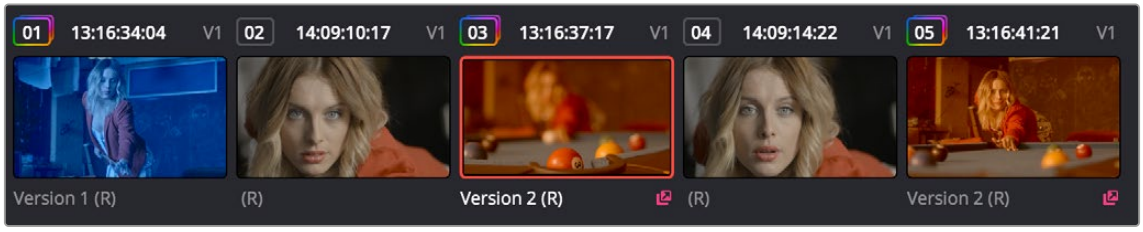
Three clips automatically linked, sharing a blue grade

Then, you set Clip 3 to use Version 2 with a different grade, tinted red. Clip 3 is now unlinked from Clips 1 and 5.



Setting the second of the three clips to use another version with a different remote grade sets it apart

However, switching Clip 5 to also use the red-tinted Version 2 means that Clip 3 and Clip 5 are now linked together, but Clip 1 is no longer linked.



Setting the third of these clips to share the same remote version as the second clip now links those two together, omitting the first clip

Every new remote version you create, and every change you make, becomes available to all other clips in all other timelines that comes from the same source Media Pool clip as the shot you're working on. However, any clip can use any version, and which version is used by a linked clip is not rippled.

For example, Timeline 1 contains a clip named Max CU, which has three remote versions. Timeline 5 also contains Max CU, which is currently set to use Version 2. If you open Timeline 1 and add one more remote version to Max CU, that new version will also be available to Max CU in Timeline 5, but it will still be set to use Version 2.

Switching Clips Between Local and Remote Versions

You can also suspend remote version grade linking by switching individual clips to use local versions. This makes it easy to create a situation where some clips are linked, and other clips are not. Keep in mind that each clip has both local and remote versions, so you can switch from one to the other without losing anything.

To suspend linking by setting individual clips to use a local version:

- Right-click a clip thumbnail, choose the submenu of the corresponding remote version you want to copy, and choose Copy to Local. The remote version is copied to a local version, which now appears as the current version that's used.

  You can also set every clip in the entire timeline to use local versions. If you switch an entire timeline to local versions, then no clip in that timeline will be linked to any other unless you create a group (covered later in this chapter). This is the default state, but it's useful even when you've switched to using remote versions when you want to grade one timeline differently from the others in a project, for example when doing a trim pass for another video or stereo 3D format, or when grading another cut, such as a trailer, that uses the same media but requires a different look.

To suspend linking by switching from remote versions to local versions:

- Right-click any clip thumbnail, and choose one of the following commands;

  Use Local Grades: Switches all clips to their local versions. If there are already local versions defined for each clip, those will appear. If there are no local versions yet defined, each clip will be ungraded.

  Copy Remote Grades to Local: Copies the currently assigned remote version of each clip to a local version.

  Because Undo is used only for individual clip operations, the Use Local Grades and Copy Remote Grades To Local commands cannot be undone. However, switching a timeline from remote to local versions is not a one-way trip. You can select Use Remote Grades to switch every clip in a timeline back to the remote versions at any time.

To switch a timeline back to using remote versions:

- Right-click any clip thumbnail, and choose Use Remote Grades.

  Furthermore, you can also copy the local grades you made to be remote grades, for instances where you started grading with local grades, and you want to switch to remote grading using your

local grades as a starting point. Be aware that when you do this in a timeline with many clips that share the same source media, the grade of the very last shared clip in the Timeline will be the only remote grade that's used for those auto-linked clips.

To copy each clip's local grade to a remote grade for every clip in the current timeline:

- Right-click any clip thumbnail, and choose Copy Local Grades to Remote.

If you're switching back and forth between local and remote versions, keep the following rules in mind:

- If you select Use Remote Grades, change your remote grades, and then Copy Remote Grades To Local on that timeline again, you'll overwrite all of your previously graded local versions. This is a good workflow if you don't like what you've done with your local versions, and you want to start over by recopying the remote versions.
- If you select Use Remote Grades, change your remote grades, and then select Use Local Grades, you'll return to your previously graded local versions, as they were before you selected Use Remote Grades. This is a good workflow if you just want to switch back to your remote versions in order to copy the remote versions of specific clips to local versions.

Working with Versions

Each clip can have as many local and remote versions as you like. There are commands for creating, renaming, and deleting the versions that are available to each clip when using the pointer or keyboard shortcuts.

Additionally, DaVinci Resolve 15 introduced the ability to batch create, rename, load, and delete versions for multiple clips that are selected at the same time.

To create a new local or remote version quickly for one or more selected clips:

- Choose Color > Grade Version > Add (Command-Y).

  A new version is created, identical to the type of version that was previously selected (remote or local), named "Version x" where x is the number of the versions that have been created. All keyframes and motion tracking are copied from the previously selected version to the new one.

To create a new version for one or more selected clips, with the option to set a name and whether to copy keyframes:

1. Right-click one of the selected clip thumbnails, and choose one of the following:
   - Local Versions > Create New Version
   - Remote Versions > Create New Version
2. Type a name for the version in the dialog that appears, and choose either "Copy all marks" or "Copy the first mark only," depending on whether or not you want to copy all the keyframes into the new version.

NOTE: Motion tracking will be copied regardless of whether "Copy all marks" is selected or not.

3 Optionally, you can choose one of the preset version names from the drop-down list. These names are defined in the Versions section of the General Options panel of the Project Settings.

4 Click OK.

To delete a specific version for one or more selected clips:

- Right-click one of the selected clip thumbnails, choose the submenu of the remote version you want to delete (it can't be the currently selected version), and choose Delete.

To delete all versions for one or more selected clips:

- Right-click one of the selected clip thumbnails, and choose one of the following commands from the contextual menu corresponding to the scope of the versions you want to delete;
  - Local Versions > Delete All Versions
  - Remote Versions > Delete All Versions
  - Delete All Versions

All versions are deleted as specified, except for the currently selected version, which is now the only one remaining.

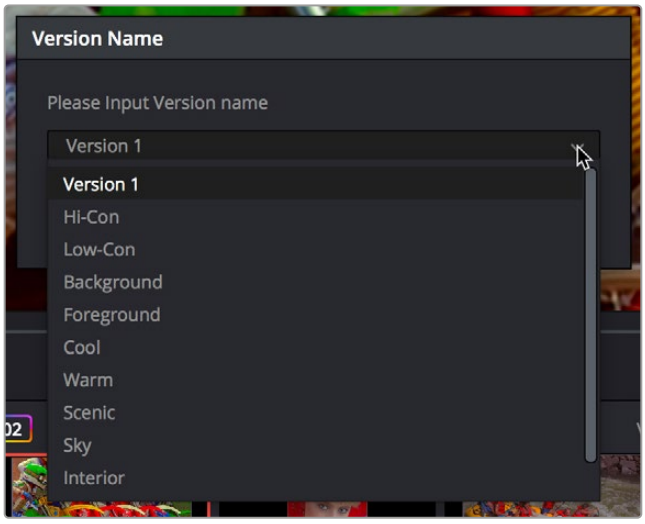
To load a particular remote or local version for one or more selected clips:

- Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to copy, and choose Load.

To rename the version of one or more selected clips:

1 Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to rename, and choose Rename.

2 In the Version Name dialog, type a name into the text field. Optionally, you can choose one of the preset version names from the drop-down list. These names are defined in the Versions section of the General Options panel of the Project Settings.

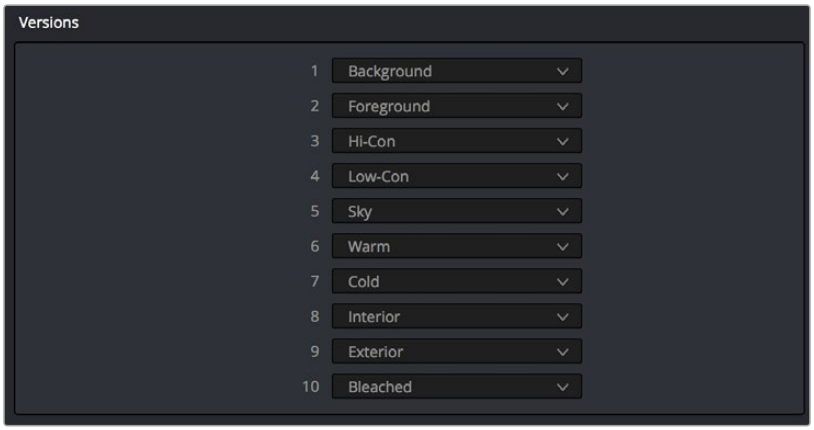


Selecting a Version name from the dropdown list, the names on the list come from assignments made using the Versions section of the General Options panel of the Project Settings

3 Click OK.

That name now appears underneath the clip thumbnail in the Timeline.

If you're going to use predefined names for versions, you need to define these in the Versions group of the General Options panel of the Project Settings. Ten drop-down menus let you choose from preset version names, or enter your own. These names will appear in the drop-down menu of the Version Name dialog.



The Versions section of the Project Settings

The Importance of "Version 1"

There are specific operations in DaVinci Resolve where "Version 1," otherwise known as "the default version," is the only version that's used, regardless of how many other versions are available, or which version was previously selected. The default version can be named anything you want, but whatever its name, the default version is the first version in the list, and it's important. Here are some examples:

- **Importing additional timelines that use the same clips:** In this case, if you're importing timelines and "Use local version for new clips in timeline" is disabled in the Color section of the General Options panel of the Project Settings, then only the default version of each clip is relinked.
- **Whenever you switch a timeline between local and remote versions:** In this case, every clip in the Timeline will be switched to the default version, regardless of what you had selected previously.

Consequently, if you plan to reconform your clips to a newer version of the edit that you're importing, or pursue other workflows that are off the beaten path, it's a good idea to make sure, no matter how many versions you end up creating, that the most important grade is always copied back to the default version.

To copy any version quickly to the default version:

1. Choose Color > Memories > Save Memory A (Option-1). You can use any memory you want, but Memory A is convenient for this example.
2. Choose Color > Grade Version > Default (Command-U).
3. Choose Color > Memories > Load Memory A (Command-1) to apply the saved memory to the default version.

To jump immediately to the default version, do one of the following:

- Choose Color > Grade Version > Default (Command-U).
- Press DEFAULT VERSION on the T-bar panel.

Deleting Unused Versions

In cases where you want to make absolutely sure there's no alternative to the grade you want a clip to have, there's an easy way to delete all versions except for the version that's currently in use, thereby making it the default version.

To eliminate either local or remote versions except for the current version:

1. Choose the local or remote version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete Unused Versions from the contextual menu.

If you selected a local version, all unused local versions will be deleted, but remote versions will be left alone. Similarly, if you selected a remote version, all unused remote versions will be deleted, but local versions will be left alone.

To eliminate all other local and remote versions except for the current version:

1. Choose the version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete All Versions from the contextual menu.

   Regardless of whether you selected a local or remote version, all other local and remote versions not in use will be deleted.

Rendering Versions

When the time comes to render your clips in the Deliver page, each clip's currently selected version will be rendered. If you need to render a different version for a given clip, you can either make sure it's selected in the Color Page timeline before you open the Deliver page, or use the Versions submenu in the Color mode of the Deliver page Thumbnail timeline. This contextual menu also provides access to the Stereo 3D commands, the Edit PAR (Pixel Aspect Ratio) command, and a command for updating the Render Window Timeline thumbnails to reflect any changes you've made in case they haven't updated automatically.

Additionally, the Commercial Workflow output option, located in the Deliver page, provides a method of rendering multiple versions for each clip when outputting your project in Source Order (as individual media files). There are two additional options in the Version submenus of each clip in the Thumbnail timeline contextual menu that let you control which versions are rendered when you use Commercial Workflow.

- **Render Disabled:** Turning this option on excludes that version from being rendered when Commercial Workflow is enabled.
- **Enable Flat Pass:** Turning this option on forces the selected version to render with the grade turned off, essentially outputting the original media.

For more information on rendering versions using the Commercial Workflow option, *see Chapter 184, "Rendering Media."*

Copying Grades

There are various methods you can use to copy grades from one clip to another. Which is appropriate to your need depends on your style of working with DaVinci Resolve.

Protecting Adjustments with the Copy Grade Options

Before going into the myriad of ways that grades can be copied from one clip to another, you should know of a series of options, available from the contextual menu of the Gallery (right-click anywhere in the gray area of the Gallery), that let you carefully specify grading, sizing, and stereo data to be preserved when overwriting grades in clips you're copying to. There are three options:

- **Copy Grade: Preserve number of nodes:** Lets you choose 0–10 nodes to be protected when applying a grade. When set to 1, the first node of the copied grade is ignored, but all other nodes are copied. When set to 5, the first five nodes of a copied grade are ignored, as long as there are at least five nodes in the grade of the clip you're copying to. This option is useful for colorists who routinely use the first few nodes for shot matching and scene balancing, with additional nodes applying individual or stylistic adjustments.
- **Copy Grade: Preserve Camera Raw Settings:** When enabled, the camera raw Source settings of the current clip are preserved, letting you apply stylistic grades from unrelated clips without overwriting clip-specific source settings.
- **Copy Grade: Preserve Input Sizing:** When enabled, Input Sizing adjustments are not overwritten by those of the copied grade.
- **Copy Grade: Preserve Convergence:** When enabled, Convergence adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.
- **Copy Grade: Preserve Floating Windows:** When enabled, Floating Windows adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.
- **Copy Grade: Preserve Auto Align**: When enabled, Auto Alignment adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.
- **Copy Grade: Preserve Dolby Vision™ Analysis Metadata**: When enabled, Dolby Vision Analysis Metadata is not overwritten by that of the copied grade. Only available if you're set up to do Dolby Vision grading.

For more information, *see Chapter 9, "Data Levels, Color Management, and ACES."*

- **Copy Grade: Preserve Dolby Vision™ Trim Metadata**: When enabled, Dolby Vision Trim Metadata in the Dolby Vision palette is not overwritten by that of the copied grade. Only available if you're set up to do Dolby Vision grading.

For more information, *see Chapter 9, "Data Levels, Color Management, and ACES."*

Copy and Paste From One Clip to Another

The simplest way to copy color adjustments from one clip and apply them to another clip is to use the same Edit > Copy and Paste commands shared with nearly every other application ever made. However, you can use this straightforward functionality in one of two ways, depending on the focus of the interface.

- If you click on the clip in the Thumbnail Timeline, you copy and paste the entire grade from one clip to another.
- If you click inside the Node Editor, you copy and paste only the selected node to another selected node.

You can override this focus-based selection, and make the default behavior to only copy between nodes rather than entire grades regardless of the interface focus. Do this by checking the “Always perform copy and paste on selected nodes” box in the Color section of the User panel in Preferences.

Methods of copying and pasting grades and node adjustments.

- **To copy and paste an entire grade:** Choose a clip with a grade you want to copy, and press Command-C. Then select the clip you want to copy the grade to in the Thumbnail Timeline, and choose Command-V to paste the entire grade.
- **To copy and paste a single node:** Choose a clip with a node you want to copy, and press Command-C. Then select the clip you want to copy the node to in the Thumbnail Timeline, and then click anywhere inside the Node Editor. Then choose Command-V to paste the node that was selected when you copied to the currently selected node in the node tree.

Copy and Paste Specific Parameters Using Paste Value

The Edit > Paste Value (Shift-Option-V) command lets you paste only the value of a specific parameter into the node of another clip.

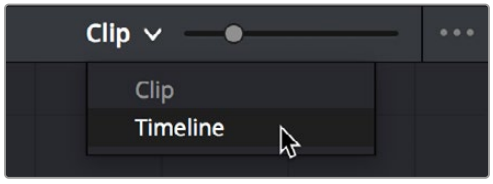
To paste only a specific value:

1. Select a Corrector node with a parameter you want to copy, and press Command-C to copy it. You’re really copying the entire grade, but that’s okay.
2. Choose any other node in any grade, and open the palette that contains the parameter you want to paste into.
3. Double-click the number field of the specific parameter you want to paste the copied value into.
4. Choose Edit > Paste Value (Shift-Option-V) to paste that value.

NOTE: Paste Value only works for parameters within palettes; it does not work for OFX or Resolve FX in the Inspector.

Applying Saved Grades From the Gallery

Every time you save a still into the Gallery or a memory, it contains both the Clip grade, and the Timeline grade, if one is applied. Which grade is applied from a still using the Apply Grade or Append Node Graph commands depends on which mode the Node Editor is in. This is selectable from the drop-down menu in the upper right-hand corner of the Node Editor.



Node Editor Clip and Track selector

If you're in Clip mode, you'll only copy the saved clip grade. If you're in Timeline mode, you'll only copy the saved timeline grade.

NOTE: This mechanism also works for saving and applying grades for clips that are in Groups. The currently selected group grade in the Node Editor determines which grade is saved with a still, and the currently selected mode in the Node Editor determines where a saved grade will be applied.

Preparing to Copy or Apply Grades

For all other methods of copying or applying grades described in this chapter, there are some common methods of controlling how adjustments from the clip or still you're copying from are applied to the clip you're pasting or applying to.

Choosing Which Aspect of a Grade to Apply with All/Color/Sizing

When applying grades using any of the techniques described in this section, you can use the All/Color/Sizing setting that are available via the Mark > Keyframe Timeline Mode submenu, the drop-down menu that's visible at the upper-right of the Keyframes Editor. When copying a grade in conjunction with the settings in this menu, the following rules apply:

- **All:** When All is selected, both the grade and the sizing are copied.
- **Color:** Only the grade is copied, the target clip retains its original Input Sizing settings.
- **Sizing:** Only the Input Sizing is copied, the target clip retains its original grade.

Choosing How to Copy Keyframes

When copying or applying grades that have keyframes, you can choose how these keyframes are copied via a setting in the Gallery contextual menu by right-clicking anywhere in the gray background area of the Gallery, and choosing one of these options from the Apply Grades Using submenu. There are three options:

- **No Keyframes:** No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.
- **Keyframes Aligning Source Timecode:** Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you're copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).
- **Keyframes Aligning Start Frame:** Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you're copying a grade with keyframes from one clip to a completely different clip, with different timecode.

From that point on, keyframes, should they exist, will be copied or applied using the selected method whenever you copy a grade using any of the previously described methods.

Copying Grades Using the Pointer

An incredibly easy way of copying a grade from one clip to another, or from a still or memory in the Gallery to a clip, is by using the third button of your mouse, usually mapped as the "middle-click" of the mouse scroll wheel.

To copy a grade from a clip or still to one or more clips using the pointer:

1. Select the clip thumbnail you want to copy the grade to in the Timeline; a single selected clip appears highlighted orange. If you want to copy a grade to several clips, you can either Command-click multiple non-adjacent clips, or Shift-click a continuous range of clips; multiple selected clips appear highlighted red.
2. Middle-click the clip thumbnail, Gallery still, or memory you want to copy the grade from.

The grade of the clip you middle-clicked is copied to the previously selected clip or clips.

> **TIP:** If you're using a trackpad, third-party software may allow you to define a "three-finger-click" that works the same as mouse button 3. If you're a pen and tablet or trackball user, you may be able to define a stylus or other button to perform the same button-3 action.

If you don't have access to a middle-click on the pointing device you're using, there's another way of doing this using a contextual menu command.

To copy a grade from a clip or still to one or more clips using the Apply Grade command:

1. Select the clip thumbnail you want to copy the grade to in the Timeline; a single selected clip appears highlighted orange. If you want to copy a grade to several clips, you can either Command-click multiple non-adjacent clips, or Shift-click a continuous range of clips; multiple selected clips appear highlighted red.
2. Right-click the clip thumbnail, Gallery still, or memory you want to copy the grade from, and choose Apply Grade from the contextual menu.

The grade of the clip you middle-clicked is copied to the previously selected clip or clips.

Copy Forward Commands

Another simple way of copying grades is to use the equals (=) and minus (–) keys on the keyboard to copy grades forward from one or two clips behind the currently selected clip. This is a great way to copy grades in scenes with a shot-reverse-shot structure, where you're cutting between two angles of coverage, each of which uses the same grade.

To copy grades forward:

- **To copy a grade from one clip back:** Choose Color > Apply Grade From One Clip Prior, or press Equals (=).
- **To copy a grade from two clips back:** Choose Color > Apply Grade From Two Clips Prior, or press Minus (–).

Copying Using Memories

Memories are virtually identical to stills, except that they're labeled with a letter (A–Z) for easy access via keyboard shortcuts. A memory bank above the Gallery browser provides a visual reference of which saved grade is assigned to which letter. This makes it easy to keep track of multiple saved memories in instances where you're copying them to several different clips throughout a scene or program.

For example, you might save a memory for each angle of coverage in a complicated scene, making it easy to copy grades forward. In another example, you might save a memory for the grade applied to each interview subject's headshot in a documentary, so you can copy that grade forward as you work through the documentary.

To save the current clip's grade to a memory for future use, do one of the following:

- Choose Color > Memories > Save Memory A–H (Option-1–8).

If you save a grade to a memory that already contains something, the previous memory is overwritten.

To apply a memory to one or more clips in a timeline, do one of the following:

1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-Clicking or Shift-Clicking.
2. Do one of the following to copy a grade to the selected clips:
   - Right-click a memory and choose Apply Grade.
   - Choose Color > Memories > Load Memory A–H (Command-1–8).

To clear a memory:

- Right-click a memory, then choose Clear.

Copying Using Preview Memory

You can also preview the effect of a memory or saved grade on the current clip, with the option to either keep it if it works, or go back to the previous grade if it doesn't.

To Preview Memory:

1. Move the playhead to a clip for which you want to preview a memory.
2. Choose Color > Preview Memory (Option-Shift-P).
3. Do one of the following:
   - Right-click any saved still in the Gallery and choose Apply Grade.
   - Choose Memories > Load > Memory A–H (Command-1–8).

   The selected grade or memory is now being previewed.
4. Now, do one of the following to either accept or reject the memory:
   - If you like the effect, then you can leave it be and move on to another clip.
   - If you don't like the effect, then choosing Color > Preview Memory (Option-Shift-P) again reverts the clip to the original grade.

Copying from Stills in the Gallery

As mentioned previously, each still you store in the Gallery contains the grading information as well as the image of the frame it was saved from. This saved grade can be applied to any clip in the Timeline.

IMPORTANT: Copied grades overwrite any previously existing grades on the clip or clips you copy to.

To apply a grade from a still to one or more selected clips in a timeline:

1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-clicking or Shift-clicking.
2. Do one of the following to copy a grade to the selected clips:
   - Drag the still from the Gallery into the Viewer.
   - Right-click a still in the Gallery and choose Apply Grade.
   - Middle-click a still in the Gallery.
   - Double-click a still to wipe it in the Viewer against the current clip in the Timeline, then right-click the Viewer and choose one of the options from the Apply Grade submenu.

Append Node Graph

You can also append a saved grade to any clip in a timeline. This adds the entire node graph of the saved still to the end of the node tree of the current clip. In other words, the current clip's grade isn't overwritten, the applied grade is added to the end of it.

By planning ahead, you can save fragmentary grades that create specific effects or adjustments using only a few nodes. You can then use these fragmentary grades as a toolkit that you can add to other grades in order to mix and match different adjustments and effects.

For example, you could create a three-node glow effect, save it, and then apply that effect at the end of a completely different clip's grade.

Appending grades places them after the original nodes

To append a saved grade or memory as individual nodes, do one of the following:

- Drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended within the node tree starting at that connection.
- Right-click a still or memory in the Gallery, and choose Append Node Graph.

Ordinarily, when you append the node graph from a memory or still to another node graph, you end up adding a whole shedload of new nodes. This may be exactly what you need, but in situations where you want to keep things a bit tidier, you also have the option of appending node graphs as compound nodes.

To append a saved grade or memory as a compound node:

- Command-drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended to the node tree as a single compound node.

NOTE: When you append the nodes from a gallery still to a grade, how keyframes are applied depends on the "Apply Grades Using" setting of the Gallery.

For more information, *see Chapter 139, "Using the Gallery."*

Aligning Keyframes to a Specific Frame While Copying Grades

If you need to copy a grade with keyframes so that the start keyframe of the copied grade aligns with a specific frame of the Timeline, you can do so using the following procedure:

To copy a grade and align its keyframes to a specific frame of the Timeline:

1. Save a grade with keyframes as a Gallery still by right-clicking the Viewer and choosing Grab Still.
2. Choose the clip you want to copy the saved grade to in the Thumbnail timeline.
3. Double-click the Gallery still to wipe it against the current clip in the Viewer.
4. Move the playhead to the frame of this clip you want the first keyframe of the saved grade to be aligned with.
5. Right-click the Viewer and choose Apply Grade > Align Keyframes to Current Frame.

Copying Individual Nodes and Settings

Copying grades from clip to clip copies everything except for keyframes and motion tracking. However, there is one way you can copy the motion tracking from one clip to another, and that's by copying and pasting individual node settings. This can save time when you're assembling complicated node trees by recycling specific nodes or node settings from previous grades.

Copying and Pasting All Settings From One Node to Another

The simplest thing you can do is to copy all of a node's settings, and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip's grade.

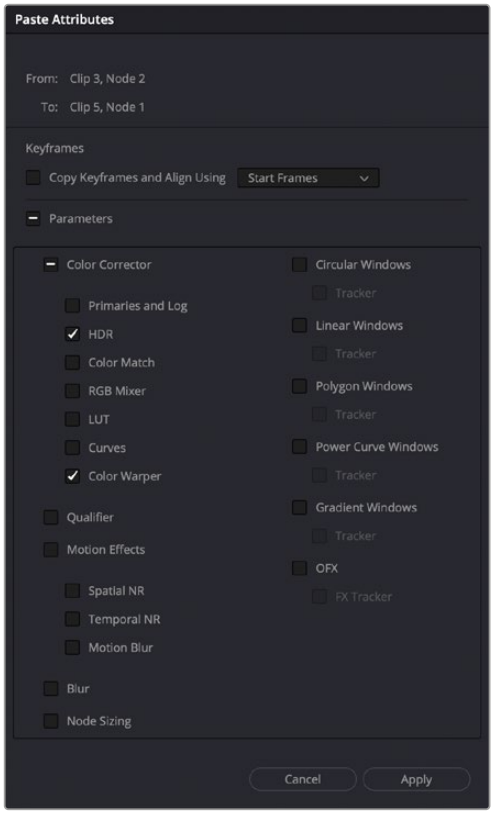
To copy a node's settings from one clip to another, do one of the following:

- Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.

- Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, or create a new node, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

Paste Attributes on the Color Page

You can copy the settings of one node and paste a subset of those settings to another selected node by choosing Edit > Paste Attributes (Option-V). A Paste Attributes window appears that shows you which node you're copying from, and which node you're pasting to, and provides controls for choosing whether you want to paste keyframes and how to align them (Start Frames or Source Timecode), as well as a series of checkboxes for choosing which palettes, windows, and OFX/ResolveFX you want to apply. You can only paste all parameters from a specified palette; there's no current provision for pasting specific parameters from within a given palette, with the exception of pasting specific windows and their accompanying trackers.



The Paste Attributes window on the Color page

Copying from the Node Graph of Other Clips or Gallery Stills

When constructing new grades, you may sometimes find it convenient to copy existing nodes or node settings from the grade of another clip or gallery still. This can be easily accomplished by exposing the node tree of any still that's saved in the Gallery, or any clip in the Thumbnail timeline, and using the controls found in the floating node graph to copy individual nodes or node adjustments to the current clip's grade shown in the Node Editor.

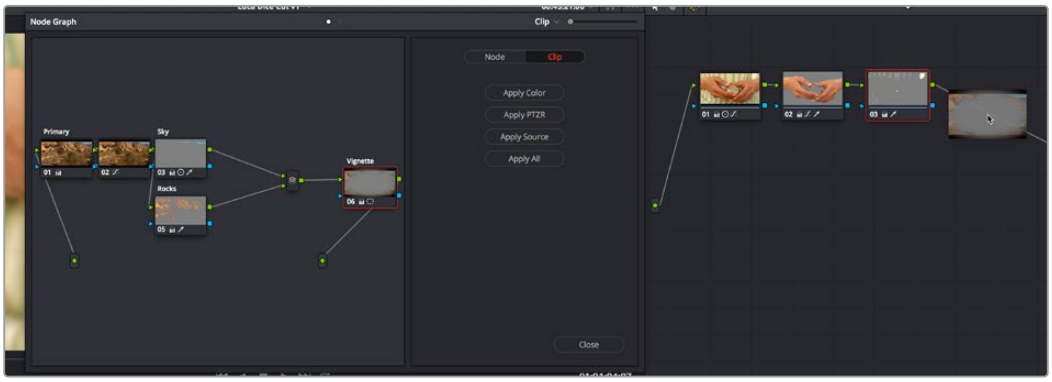
Copying Clip Settings Using Display Node Graph

In Clip mode, the floating Node Graph window has four sets of controls you can use to choose how to copy nodes and adjustments:

- **Clip Node Graph:** By default, the Clip node graph is displayed at the left. You can drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node's settings or onto a connection line to insert it as a new node.
- **Timeline Node Graph:** (Only available if there is a Timeline grade) You can switch to the Timeline grade, if there is one, by either clicking the second button in the Node Graph title bar, or by

choosing Timeline from the drop-down menu at the upper right-hand corner of the floating Node Graph window.

- **Apply Color/PTZR/Source/All buttons:** With the Clip panel selected, four buttons let you selectively copy the entire grade, the sizing, the source settings, or all settings at once to the current clip.

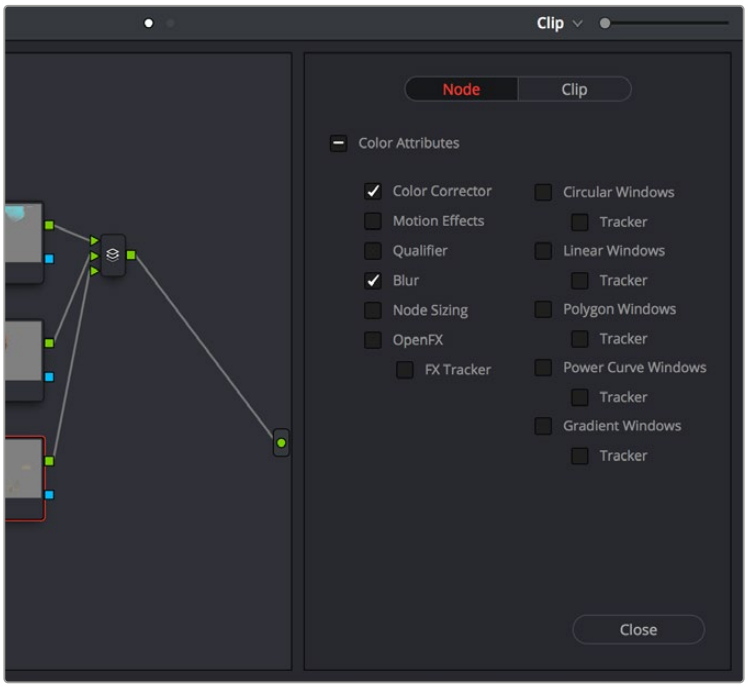


Dragging a node from another clip's node graph to the currently selected clip's grade in the Node Editor

Copying Node Settings Using Display Node Graph

In Node mode, the floating Node Graph window displays all of the available Color Attributes found within each node, instead of the Apply Color/PTZR/Source/All buttons:

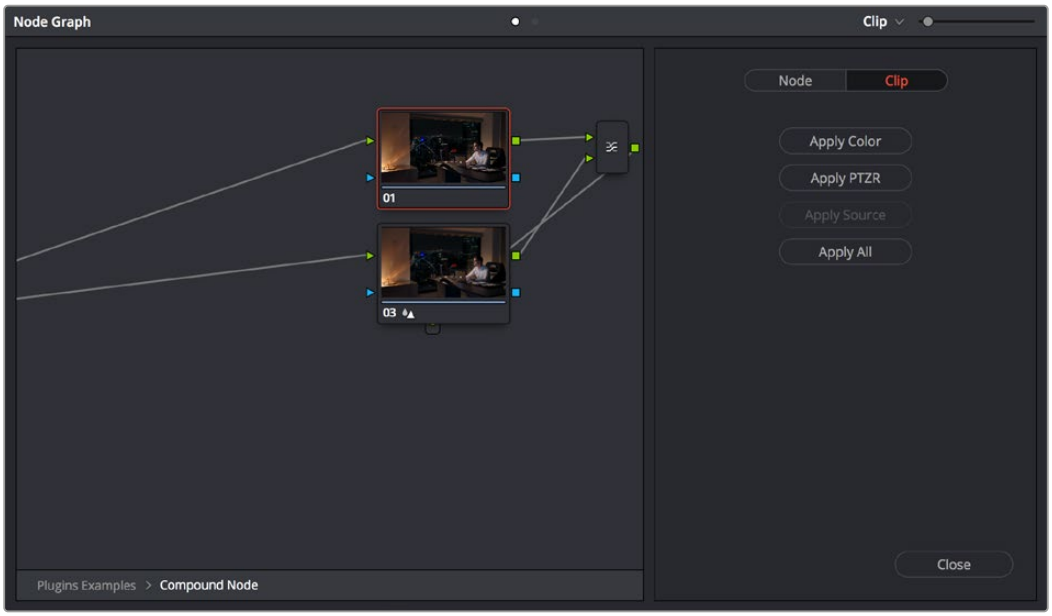
- **Node Settings:** Use the checkboxes to choose which node adjustments get copied and which do not. After you've checked the settings you want to selectively copy, dragging a node from the floating node graph onto nodes in the Node Editor copies or appends the selected attributes into the target node, leaving all other attributes alone. For Windows and OpenFX, you have the option of also copying any motion tracking that's available.



The Node panel open with the Color Corrector and Blur attributes selected for copying

Ability to Open Compound Nodes in “Display Node Graph”

When you right-click a Gallery still or a thumbnail and choose Display Node Graph for a grade that uses compound nodes, you can right-click any compound node and choose “Show compound node,” or Command-double-click a compound node to open it and see its individual nodes.



Opening a compound node in a floating Node Graph window

How to Copy Nodes Using Display Node Graph

The following procedures describe how to open the floating node graph in different situations.

To copy individual nodes or settings from any still in the Gallery:

1. Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.
2. Right-click a still in the Gallery you want to copy nodes from, and choose Display Node Graph. A floating Node Graph window appears displaying that still’s node tree.
3. (Optional) While the Gallery Node Graph window is open, you can select any other still, and this window will update to show the currently selected still’s node graph, ready for you to copy from.
4. In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.
5. Do one of the following to copy nodes or settings to the Node Editor.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that’s created.
   - In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.

- In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.
- In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.
- In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.
- In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.
- In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.

6 While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that's displayed in the Node Editor, ready for you to copy to.

7 Click Close when you're finished.

To copy individual nodes or settings from any clip in the Timeline:

1 Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.

2 Right-click the thumbnail of another clip you want to copy nodes from, and choose Display Node Graph.

> **NOTE:** The Display Node Graph command only appears in the contextual menu of a clip in the Thumbnail timeline that is not currently selected.

3 (Optional) In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.

4 Do one of the following to copy nodes or settings to the Node Editor.

- In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node's settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
- In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that's created.
- In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.
- In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.
- In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.
- In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.
- In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.
- In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.

5 (Optional) While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that's displayed in the Node Editor, ready for you to copy to.

6 Click Close when you're finished.

Rippling Adjustments Among Multiple Clips

If you've graded a sequence of clips and find yourself needing to make a quick change to several clips all at once, you can use the Color > Ripple Node Changes to Selected Clips/Current Group commands to quickly copy changes made to one clip to several others. However, these commands require that you follow certain rules in order to get the results you want.

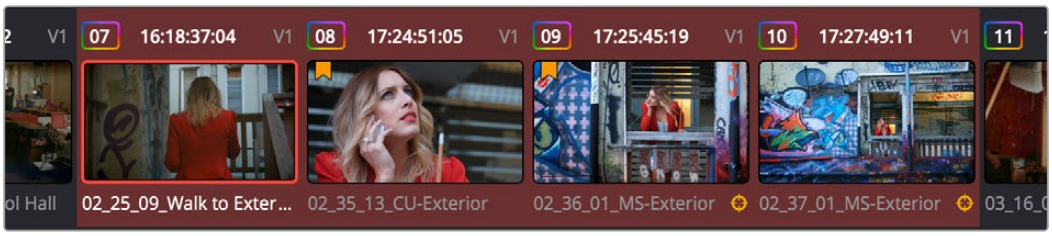
Node rippling uses the number of each node to determine what changes should ripple to which nodes. In other words, changes made to Node 3 will ripple to Node 3 of every other selected clip, or to Node 3 of every other clip in the current group (depending on which command you use).

Rippling changes from one clip to several others requires that all clips share the same number of nodes, at least for the nodes you're rippling. If you try to ripple a change to one or more clips that don't have a node with the same number as the one you're rippling, then no change will be rippled to those clips.

To ripple a change in one node to several selected clips:

1 Select the clip you want to use to make the change so that it's the current clip, outlined in orange.

2 Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they're all selected red.



The orange outlined clip is the current clip you're modifying, and the clips highlighted in red are the ones you're rippling this change to

You don't have to select the clips you're going to ripple your change to prior to making the change, but it may be easier to keep track of what you're doing if you set everything up in advance. The clip you're changing should be outlined in orange, and the clips you're rippling the change to should be highlighted in red.

3 Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you're modifying. If some clips don't, then those clips won't inherit the change you're going to be rippling.

4 Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren't node-specific.

5 When you're happy with the change you've made, choose Color > Ripple Node Changes to Selected Clips.

The change you've made should ripple to every other selected clip with a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.

If you've created a group, it's even easier to ripple node adjustments to the other clips in the group.

To ripple a change in one node to the current group:

1. Select the clip you want to use to make the change so that it's the current clip, outlined in orange. It must be part of a group for this to work.
2. Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you're modifying. If some clips don't, then those clips won't inherit the change you're going to be rippling.
3. Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren't node-specific.
4. When you're happy with the change you've made, choose Color > Ripple Node Changes to Current Group.

   The change you've made should ripple to every other clip in the current group that has a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.

Appending a Node to Multiple Clips

If you've made an adjustment to a node in one clip that you'd like to apply to several other clips, you can quickly do that using the Color > Append Node to Selected Clips command. You can do this as a prelude to using one of the Ripple Node Change commands, as it's a quick way to make sure several previously ungraded clips have the same nodes, but you can also do this as a quick way to apply the same node change to several clips, regardless of whether they have matching node trees.

To append a node to other selected clips:

1. Select the clip you want to use to make the change so that it's the current clip, outlined in orange.
2. Select the node you want to append to other clips.
3. Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they're all selected red.

   The clip you're copying from should be outlined in orange, and the clips you're rippling the change to should be highlighted in red.
4. Choose Color > Append Node to Selected Clips.

   The selected node should be appended to the end of the node tree of each selected clip, and in a few moments the thumbnails of those clips should update to show the change.

Using Shared Nodes

Shared nodes are meant to be a way to extend the benefits of automatically rippled changes among different clips to colorists that prefer a flatter node structure than Group Grading allows. By turning individual Corrector nodes into Shared nodes, and copying these to multiple clips, you enable linked adjustments right from within the clip grade. This means that the clip grade can freely mix both clip-specific nodes and Shared nodes, all within the same node tree. This makes Shared nodes fast to use as there's no need to create groups or switch to a group node tree (covered in the next section) to reap the benefits of linked adjustments among multiple clips.

A grade with an Unshared (at left) and Shared node (at center), a badge indicates the Shared node, which is also locked

What Are Shared Nodes Good For?

Shared nodes are similar to group grades, except that they don't require grouping and can be added to any normal grade. Changes made to a Shared node are automatically rippled to all other instances of that node in the grades of other clips. Furthermore, you can add as many Shared nodes to a grade as you like, and you can arrange them in any order to control the order of the operations they apply. And, of course, you can intersperse them with ordinary Corrector nodes

Shared nodes are extremely flexible. For example, you can use Shared nodes to:

- Add a Color Space Transform Resolve FX or a LUT to the beginning of every clip from a particular source
- Add a base correction to every talking head shot of a particular interviewee
- Add a shot matching adjustment to each clip from a particular angle of coverage within a scene
- Add a stylistic adjustment to every clip in a specific scene
- Make your base adjustments when grading with remote versions, so those adjustments remain linked when you copy your remote versions to local versions for fine tuning

In fact, you can mix and match Shared nodes among differently overlapping sets of clips to accomplish any or all of the above at once. For example, you can add one Shared node to make an adjustment to every clip from a particular camera, add a second Shared node to each of those clips that are in a particular scene, and then add a third Shared node to whichever of those clips happen to be a closeup of the lead actress, before adding one or two regular Corrector nodes that aren't shared to make clip-specific tweaks.

IMPORTANT: At the time of this writing, there is a limitation when using Shared nodes. Grades using shared nodes cannot be used in collaborative workflows. It is hoped that this limitation is temporary.

Creating Shared Nodes

Creating a Shared node is easy, assuming you've created a node that has an adjustment you'd like to share among multiple clips.

To create a Shared node:

- Right-click any Corrector node and choose Save as Shared node.

Locking Shared Nodes

Once you turn a node into a Shared node, that node is automatically locked, preventing you from accidentally making adjustments to it that would affect all other grades using that same Shared node.

To toggle the locked status of a Shared node, do one of the following:

- Right-click any Shared node and choose Lock Node from the contextual menu.
- Open the Keyframe Editor, and click the Lock icon in the track header of that node's keyframe track.

Copying Shared Nodes

Because Shared nodes are essentially Corrector nodes within clip grades, they're easy to work with. Once you've created one or more Shared nodes, there are a variety of ways you can copy them to the grades of other clips in your program to take advantage of the linked adjustments they let you make.

Ways of copying Shared nodes among multiple clips:

- **Add a Shared node to another clip's grade using the Node Editor contextual menu:** Once you save a node as a Shared node, it becomes available from the bottom of the Add Node submenu of the Node Editor contextual menu, making it easy to add any Shared node to any clip. If you customize the label of the Shared node, that custom label appears in the contextual menu, making it easier to find what you're looking for.
- **Add Shared nodes to a basic grade you'll be copying to other clips:** If you create one or more Shared nodes when you initially build a grade, copying that grade to other clips naturally copies the Shared nodes as well.
- **Save a Shared node as a Gallery still and apply it to other clips:** If you save a grade with a Shared node in it to the Gallery, then every time you copy that Gallery still to another clip, you copy its Shared node.
- **Create a Shared node and append it to a selection of additional clips:** If you've already graded several clips in a scene, you can add a Shared node to the end of one of the clips grades and make sure it's selected, then select all of the other clips in the scene and choose Append Node to Selected Clips.
- **Use Shared nodes to preserve linked adjustments when copying remote grades to local grades:** If you use Shared nodes to make your base adjustments when you grade using Remote Versions to automatically copy those grades to other clips that come from the same source media, those adjustments will remain linked when you copy your remote versions to local versions for fine tuning.

You can also choose options in the Gallery that dictate what happens when you copy a grade that has shared nodes within it.

Converting Shared Nodes Back to Corrector Nodes

Sometimes you need to stop a node from being shared. For example, if you want to copy a grade from another scene to use as the starting point for a new grade, chances are you don't want any shared nodes to continue being shared as you customize that grade for the new scene. In this instance, you can convert the Shared node back to a regular Corrector node, make any adjustments you need to customize it for the new scene, and then turn that node into a brand new Shared node that's specific to the new scene.

To convert a Shared node back to a Corrector node:

- Right-click any Shared node, and choose Convert to Corrector from the contextual menu.

Deleting Shared Nodes

If you've created a Shared node that's being used in multiple clips, and you decide you want to eliminate the linked relationship among these nodes so they all work independently, you can "delete" a specific Shared node. This leaves the now unlinked nodes intact within each node tree in which they appear, but clears their effect. Additionally, that Shared node is removed from the Add Node submenu.

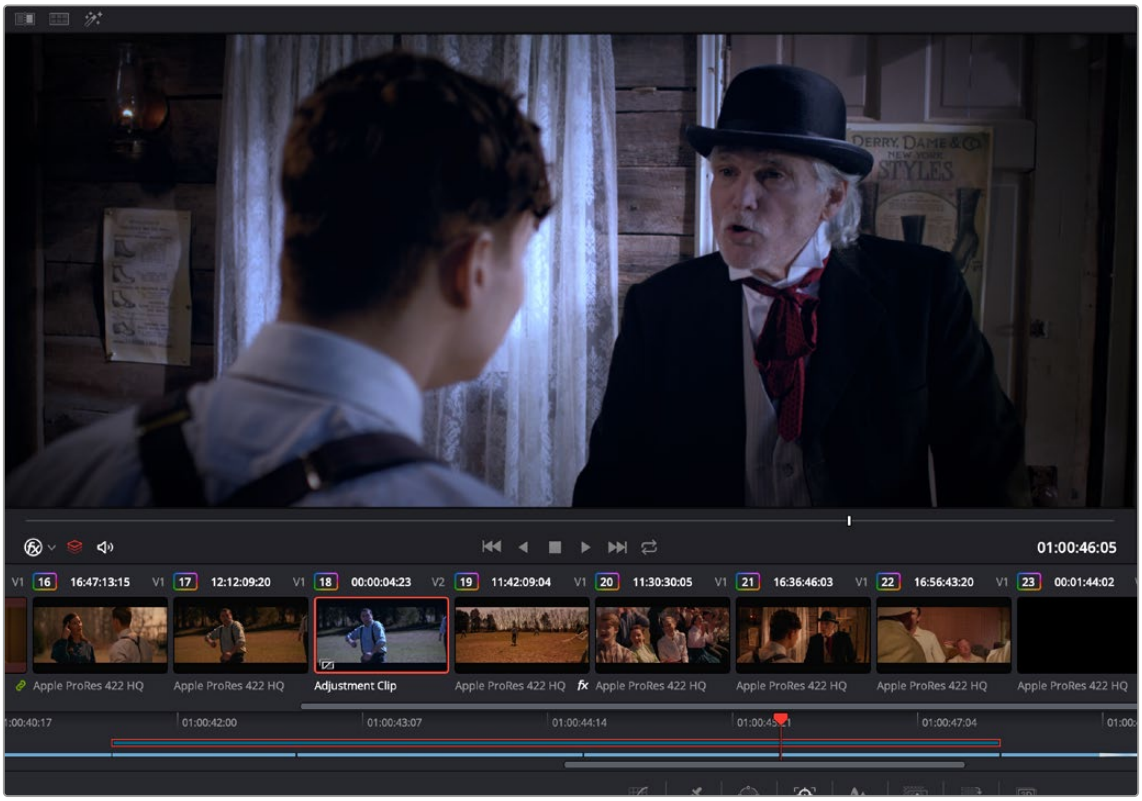
To Delete a Shared node:

- Right-click any Shared node, and choose a node to delete from the Delete Shared Node submenu.

Using Adjustment Clips

You can also apply a single grade to multiple clips in the Timeline using Adjustment clips that have been superimposed over numerous other clips in the Timeline. They can be used to apply a single grade to all clips in a scene, or to add further color adjustments or trims to a section of clips via a second grade that's applied on top of the individual clip grades that are already applied.

Adjustment clips are a great way to add adjustments to multiple clips that you may be making frequent changes to. If you make changes to a grade in an Adjustment clip, that change is automatically applied to all clips underneath it in the Timeline. Additionally, grades applied via adjustment layers can be turned off by disabling the adjustment layers, either one at a time, or by disabling an entire track with adjustment layers in it.



An Adjustment clip (shown selected in the Mini Timeline) used to apply a cooler grade to four other clips in a scene

Adjustment clips can be edited into the Timeline on the Edit page, and are available from the Effects bin of the toolbox in the Effects Library. When an Adjustment clip is superimposed above one or more clips in the Timeline, all effects that are applied to the Adjustment clip are also applied to all clips underneath it.

Adjustment clips can be used to apply the following types of effects:

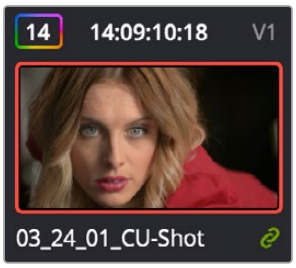
- ResolveFX and OpenFX plugins
- Inspector parameters, including Composite, Transform, Cropping, and Dynamic Zoom
- Fusion page effects
- Color page grading and sizing

Effects clips are a fast and easily revised way to apply one or more grades and effects to a range of clips.

TIP: Multiple adjustment layers can be grouped together so that you can apply Group and Clip grades to adjustment layers, linking multiple adjustment layers together in situations where you want to apply the exact same trim or stylistic adjustment to multiple scenes in non-contiguous areas of the Timeline.

Using Groups

Grouping is one of DaVinci Resolve's most powerful features for organizing grades amongst multiple clips. Groups are manually created collections of clips with automatic linking relationships that make it easy for you to control the rippling of grades among sets of clips that you define. When clips have been grouped together, selecting one member of the group reveals a group "linked" badge at the top-right of each clip's thumbnail belonging to the group.



The green link icon indicates this clip is in a group

You can create as many groups within a single project as you need. You can add or remove shots from the current group, and the current group is defined by the last shot you've selected (if it belongs to a group, that's the new current group).

Once grouped, you can choose from one of four Node Editor modes to grade the current clip. Which mode you choose determines whether that grade will automatically ripple to every other member of that group, or whether the grade will only affect that one clip. In this way, you can combine multiple node trees, some which will ripple, and one which won't, to create the final look of each clip in that group.

For example, you might group together every clip from the same angle of coverage in a scene. You might also group together every clip from a particular section of B-roll that will be graded with the same treatment. This way, whenever you make a change or otherwise update one member of the group using one of the rippled Node Editor modes, every clip in the group will be changed together.

This section discusses how to create and manage groups, how best to use them, and what issues you need to be aware of to use groups to best advantage.

Creating and Managing Groups

The following procedures describe how to create, load, modify, and delete groups.

To create a new group:

1. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose Add Into New Group.
3. Type a name into the field of the Group Name dialog, and click OK.

   The new group is created, and the clips you had selected now appear with the "linked" group badge above the thumbnails.

To load a different group, do one of the following:

- Move the playhead to another clip that's a member of that group.
- Right-click any clip belonging to any group, and choose Group > "Name of group" > Load.

  The selected group now becomes the current group. Using the Add Into Current Group command will add a clip to the newly loaded group.

To add one or more clips to an existing group:

1. Load the group you want to add clips to.
2. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
3. Right-click one of the selected clip thumbnails, and choose Group > "Name of group" > Assign to Group.

   The selected clips now appear with the "linked" group badge above the thumbnails.

To remove one or more clips from an existing group:

1. Select one or more clip thumbnails in the Timeline that you want to remove from a group. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a discontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose Remove From Group.

To rename a group:

1. Right-click any clip belonging to any group, and choose Group > "Name of group" > Rename.
2. Type a new name into the field of the Group Name dialog, and click OK.

   The group is renamed. The new name appears as a new submenu of the Timeline contextual menu.

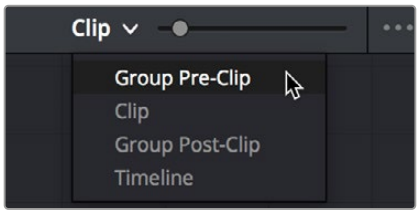
To delete a group:

- Right-click a clip belonging the group you want to delete, and choose Group > "Name of group" > Delete.
- This clears the group, while preserving the last applied grade within each clip.

DaVinci Resolve makes a default smart filter for all clips in the current group. It can be found in the Clips drop-down, under Grouped > Current Group.

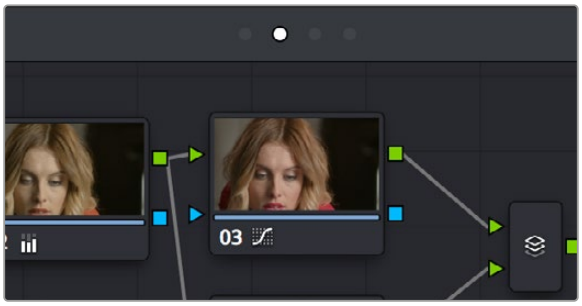
Using Group Modes to Control Which Grades Ripple and Which Don't

When you create a group and then select any clip that is a member of that group, additional Node Editor modes become available that let you apply multiple levels of grades to the clips in that group.



Available options in the Node Editor modes drop-down

For clips that aren't grouped, two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you're working on a clip that's part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well.



Four dots at the top of the Node Editor let you choose which mode you're working on

Node trees you create using the Group Pre-Clip and Group Post-Clip modes automatically ripple changes to every member of a group. Node trees created with the Clip mode are specific to each clip. Node trees created with the Timeline grade affect the entire Timeline, all at once. Combining node trees made using these different modes makes it easy combine clip-specific changes with group-wide changes that make grading faster.

- **Group Pre-Clip:** Node trees assembled in this mode affect every clip in the group simultaneously. Pre-Clip adjustments are useful for creating an overall grade that you want to use as a starting point for the scene, such as when you need to normalize a group of log-encoded clips in a specific way, or when you want to create a base grade that generally improves every clip in a scene.
- **Clip:** The Clip grade corresponds to the local or remote version associated with that clip. Node trees assembled in the Clip mode only affect the specific clip that's selected. All Local and Remote versions you create are in Clip mode. Clip adjustments are useful for matching clips to one another in a scene, doing clip-specific secondary adjustments, or making any other sort of adjustment that you only want applied to the current clip, rather than to the group as a whole. Clip adjustments are applied after Pre-Clip adjustments.
- **Group Post-Clip:** Node trees assembled in this mode also affect every clip in the group simultaneously, but these adjustments are applied after the Clip adjustments. Post-Clip adjustments can be useful for applying a creative look to an overall scene, so that later revisions to a scene's look can be accomplished with a single set of adjustments that automatically affect the entire group.
- **Timeline:** Node trees assembled in this mode affect every single clip in the entire Timeline. Timeline adjustments are useful when you have a single change that you want to apply to every single clip at once.

The image processing of each Node Editor mode is sequential, making it easy to keep track of the order of operations affecting a particular clip.

An Example of Grading a Group of Clips

This section shows an example of how you might approach grading a group of clips using the different Node Editor modes that are available. Keep in mind that this is only one of many possible approaches you could take to the use of groups, and was chosen because it exercises everything you can do to a single grade.

To get started, select a series of clips that you want to group, and right-click one of them and choose Create New Group to group them together, entering a name and clicking OK when prompted.
One convenient advantage of simply creating groups from a selection is that you're not limited to selecting a continuous range of clips in the Timeline. Another advantage is that you can use the View > Timeline Thumbnail Mode > Source (C-mode) command, or Timeline filtering, to isolate the range of clips you want to use for creating a group.

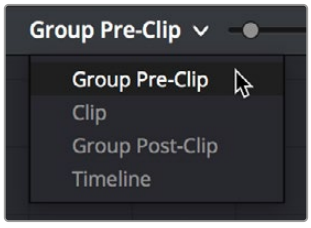
There are different ways you might choose to group clips together:

- All clips within a particular scene
- All clips recorded from a specific camera
- All headshots of a particular person
- All clips from a particular angle of coverage
- All exteriors of a particular location

The list could go on and on, but you get the idea. You can group any selection of clips together that have reason to share a common grade. In this example, a series of shots from an exterior scene are selected and made into a group.

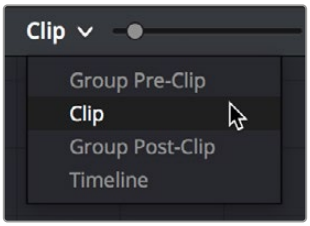
Clips made into a group

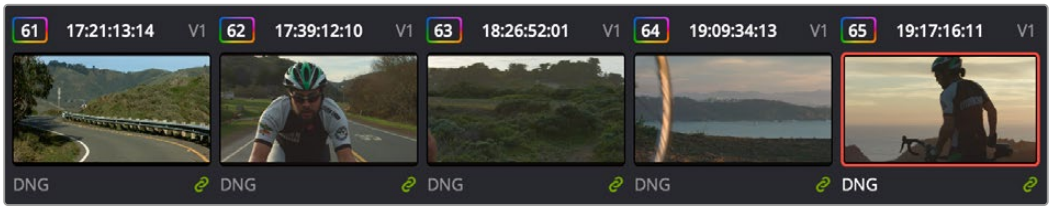
Once you've created a group, choose Group Pre-Clip from the Node Editor mode drop-down. This is the first grade that's applied, as the underlying grade that affects the entire group. Using this node tree, adding a LUT to normalize the clips, a Color Wheel adjustment, and some Curve adjustments to tune the color provide a primary grade that now affects every single clip in the group.



A primary adjustment applied to the Group Pre-Clip mode

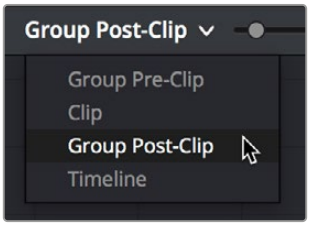
With this accomplished, you can see there's some variation among the clips in the scene that needs to be corrected in order for every clip to match. Choose Clip from the Node Editor mode drop-down. Grades that you make in Clip mode only affect the clip to which they're applied, so now you can work clip by clip using the Image Wipe and Split-Screen controls to compare clips and make whatever adjustments are necessary to make each one match the main look for the scene.

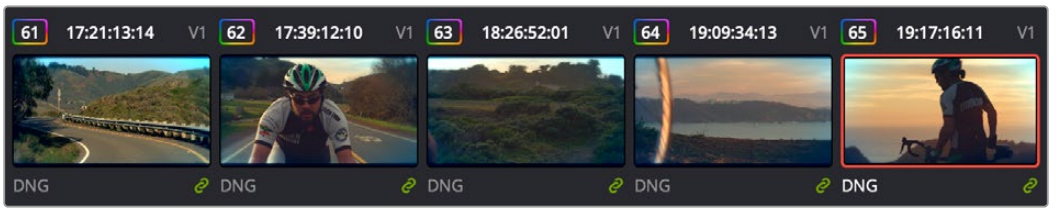




Scene balancing adjustments made using the Clip mode

Once all the clips are balanced with one another, you can choose Post-Clip Group from the Node Editor mode drop-down. This lets you add one more grade on top of the Pre-Clip and Clip grades that you've already applied, that you can use for any number of things. In this example, a single stylistic adjustment is applied that now affects all of the clips at once. If a client wants to see something different, you can easily make the necessary changes to one clip, and all other clips in that group will immediately be altered as well.





A stylistic adjustment applied to the Group Post-Clip mode

At this point, the scene is graded via a well organized set of corrections. If the client later wants a change affecting the underlying primary grade that everything is built on, you can adjust the Pre-Clip grade. If you spot an inconsistency with your shot matching at any point, you can make a fast tweak to the relevant Clip grade. And if the client wants a stylistic change, you can make any necessary adjustments to the Post-Clip grade to change the overall look of the whole scene. In each case, groups give you total control over which adjustments will ripple across the whole group, and which adjustments will be clip-specific.

Using Undo in Groups

Each Node Editor mode has a separate undo stack, meaning that separate multiple-level undo is saved for Group Pre-Clip, Clip, and Group Post-Clip.

Saving Stills and Grades in Groups

When you save a still for a clip that's part of a group, the result is that the still reflects the look of the combined Pre-Clip, Clip, and Post-Clip node trees, but the grade that's saved within depends on the Node Editor mode you had selected when saving the still. For example, if the Node Editor is set to Group Pre-Clip, then you'll only save the Pre-Clip grade; the Clip, Group Post-Clip, and Track grades will be ignored. Copying a saved grade to a clip in a group results in that grade being copied to the node tree of whichever Node Editor mode is currently open.

Collapse Group Grades

If you want to take a clip out of a group, but you want its grade to continue incorporating all adjustments made in the Pre-Group and Post-Group Node Editor modes, you can use the Collapse Group Grades command to copy all nodes in the Pre-Group and Post-Group grades to the Clip grade. When you do this, Pre-Group nodes are added before any pre-existing nodes in the Clip grade, and all Post-Group nodes are added after, in order to maintain the correct order of operations.

(Top) The Clip node tree, (Bottom) After using the Collapse Group Grades command to flatten the Pre-Group and Post-Group nodes into the Clip node tree

To flatten all group grades into a single Clip mode node tree:

- Right-click a clip's thumbnail in the Thumbnail timeline, and choose Collapse Group Grades from the contextual menu.

Using Collapse Group Grades on a clip always removes that clip from whatever group it was previously a member of. This can also be an easy way of creating a single flat node tree in preparation for saving a grade to the Gallery for applying to other clips that aren't themselves in groups.

Groups and Versions

Local or Remote versions you create relate only to the Clip grade. Group Pre-Clip and Group Post-Clip grades cannot be versioned.

Exporting Grades and LUTs

If you find it necessary to exchange grades with other workstations, there are two ways you can do so directly: by exporting grades, or LUTs. This section discusses the export of Grades.

> For more information about exporting LUTs, *see Chapter 148, "Using LUTs."*

To export a grade:

1. Save the grade you want to export as a still in the Gallery.
2. Right-click the saved still in the Gallery, and choose Export.
3. Select the image format you want to save the still as. Choices include: DPX, Cineon, TIFF, JPEG, PNG, PPM, BMP, and XPM.
4. Choose a location for the resulting still image and saved grade files, type a name into the Save As field, and click Save.

   Two files are saved. The image file contains the still image of the frame that was stored. A DRX (DaVinci Resolve eXchange) file contains all the grading information.

To Import a grade:

1. Right-click anywhere in the gray area of the Gallery, and choose Import.
2. Click the Options button to select the specific file type you want to import, or select "All Files" for multiple formats.
3. Choose the image file that was exported from your DaVinci Resolve workstation, or someone else's. The accompanying DRX file must be in the same location. If you lose the original image file, you can still import the DRX file by itself. It will preserve the node structure of the still, but you will not be able to wipe against it.

   The still you imported appears in the Gallery, containing the grading information you wanted to import.

Chapter 141

Node Editing Basics

This chapter covers the basics of using the Node Editor in DaVinci Resolve to manage all of the adjustments you decide to apply to a clip, as well as the fundamental procedures for editing and organizing nodes within a tree that are the basis for creating more sophisticated effects.

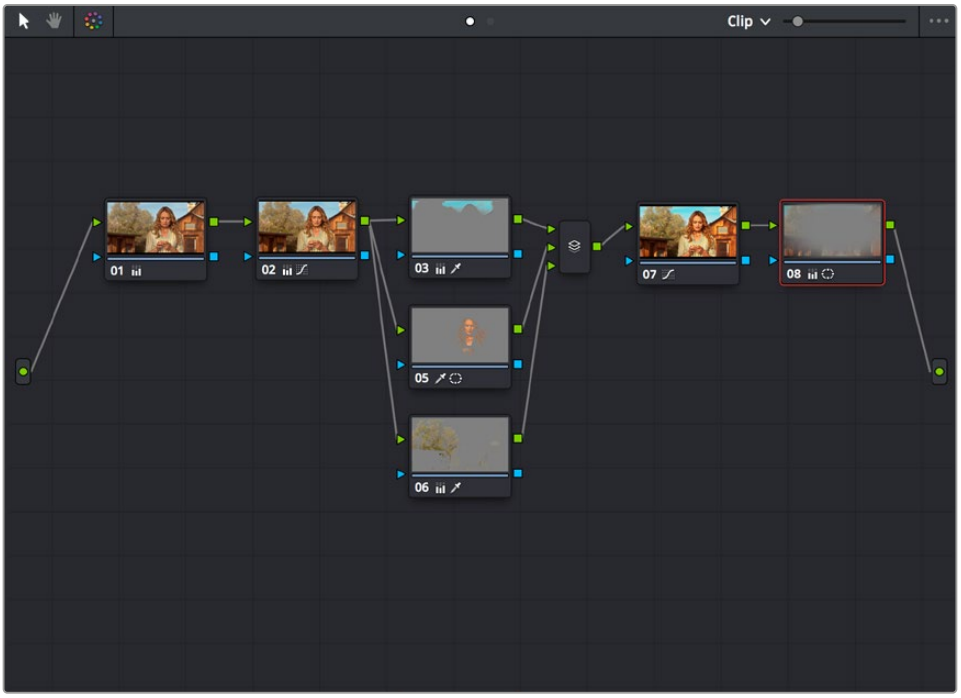
Node Editor Basics

By default, every clip has one node in the Node Editor that contains the first corrections you make. However, you also have the option of creating multiple nodes, where each node contains one or more corrections that affect the image.

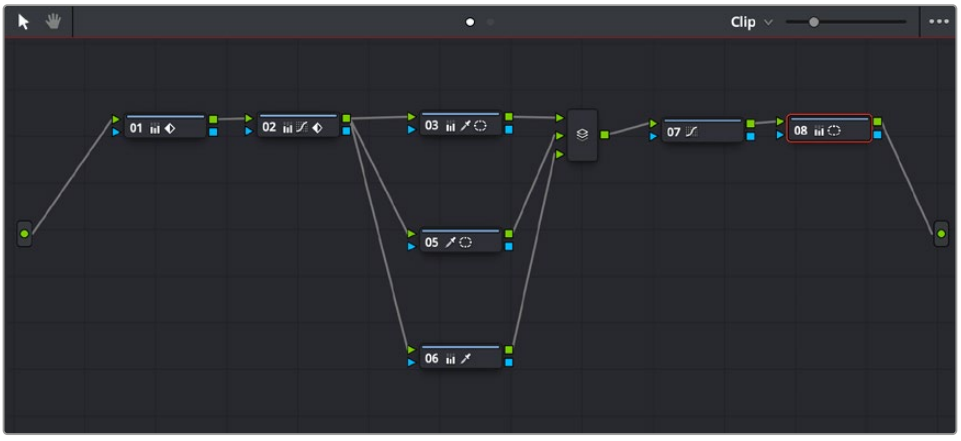


The Node Editor showing a reasonably full-featured grade

The specific arrangement of nodes you create lets you exert precise control over the order of operations performed by your grade, which provides many advantages. This section covers different ways of creating, editing, and arranging node trees to harness the full power of DaVinci Resolve.

Thumbnail-Optional Nodes

The Node Editor option menu provides a Show Thumbnails option that lets you disable or enable the thumbnails attached to each Corrector node.



Disabling thumbnails in the Node Editor option menu makes nodes shorter

How Many Nodes Do I Need to Use?

In this chapter and the ones that follow, you'll learn many different techniques for combining adjustments and nodes in different ways to achieve highly specific effects. Consequently, new DaVinci Resolve users often wonder, how far do I go? There is no right answer, but suffice it to say that some of the world's leading colorists achieve stunning results in as few as three or four nodes, while others routinely build carefully organized hierarchies of ten to twenty nodes, or more. The number of nodes you use is often dependent on the quality of media you've been given to work with, as well-lit footage usually requires less work than material shot run-and-gun with available light, that typically needs many more adjustments to achieve an acceptable result. Furthermore, the number of nodes you may use can also depend on what kind of program you're working on, with commercial spots affording the colorist enough time in the schedule to build truly massive grades that adjust every little detail, and narrative features and television shows requiring you to work faster and do more within fewer adjustments in order to stay on track. The real answer? Each grade requires as many nodes as are necessary. No more, no less.

The Node Editor Interface

As you work within the Node Editor, you may find the need to zoom into or out of it to get a better look at the node tree, and to pan around the working area to deal with large collections of nodes.

To expand the size of the Node Editor's working area:

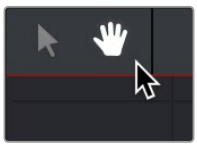
- Drag the border between the Node Editor and the Viewer to the left or right to make it wider or narrower.
- Right-click anywhere within the Node Editor (except on a node) and choose Toggle Display Mode, which hides the Viewer and moves the Node Editor to the right of the Gallery, enlarging it considerably. Right-click and choose Toggle Display Node again to return to the default layout.

To arrange the node tree to fit your current working area:

- Right-click anywhere in the Node Editor (except on a node) and chose Cleanup Node Graph from the contextual menu. This will rearrange your node tree to fit in whatever size working area you have at the time.

To zoom and pan within the Node Editor, do one of the following:

- Use the Node Editor's zoom slider to shrink or enlarge the nodes in the Node Editor.
- Click the Pan tool (the hand icon) at the upper left-hand corner of the Node Editor, and drag anywhere within the gray area of the Node Editor to pan around.
- Press the H key to toggle between selection and pan modes in the Node Editor.
- Middle-click and drag anywhere within the Node Editor to pan around.
- Right-click and choose Zoom In or Zoom Out.
- Right-click and choose Zoom to Window to fit the node tree to the current size of the node graph.
- Right-click and choose Original Size to return the node graph to the default size.



The Node Editor's Pan (Hand) tool

The Components of a Node Tree

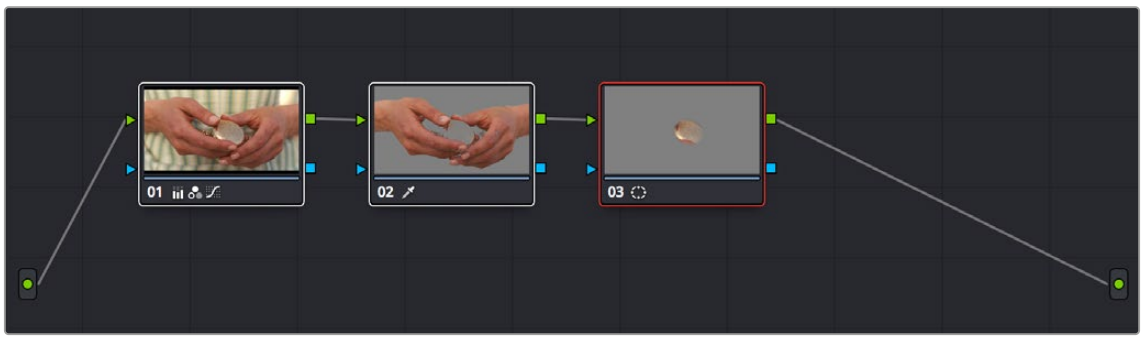
Ambitious grades may require trees of multiple nodes to create the necessary effect. This section covers the mechanics of putting nodes together into the structures that are described in more detail later in this chapter.

Every node you add is a “Corrector” node, which is capable of either primary or secondary correction, depending on whether or not you enable the Qualifier/Window/Matte controls. Even “Serial” and “Parallel” nodes are simply Corrector nodes that are added in series or in parallel to the previous node in the node tree; the names are a consequence of how they’re added.

Each Corrector node has two inputs and two outputs, which lets you separately manage the RGB image-processing channel, and the Key channel that defines areas of isolation for image processing operations, or transparency for compositing. RGB connections are light green, located at the top left and right of each node. Key connections are blue, located at the bottom left and right of each node. Inputs into the node are triangles, and outputs are squares. These inputs and outputs let you control the flow of image and isolation channels coming into and going out of each node in the tree.

A single node, the RGB (green) and key (blue) triangular inputs and square outputs are clearly visible

Nodes are attached to one another via “connections,” seen as lines that connect one node to another. Image data flows from left to right, starting with the Source input all the way at the left of the Node Editor, through each node in the tree, and ending at the Node Tree output at the right of the Node Editor.



A simple serial arrangement of corrections

Here’s an explanation of the different components of a basic node tree where all nodes are connected in serial, one after the other, and how they work together:

- **Source Input:** The green source node to the far left is the clip’s image data as processed by the Sizing and Source decode settings, ungraded. The Source input feeds RGB data to the grade, and is connected to the RGB input of the first node in your tree. If necessary, you can connect the Source input to more than one Corrector node, creating multiple simultaneous streams of image processing emerging from the original source state of the image that you can eventually recombine in different ways using the Parallel or Layer Mixer nodes.

- **Nodes:** Each node in the node graph represents a collection of image processing operations that can be enabled or disabled separately from any other node in the graph. By separating operations into multiple nodes, you're able to precisely control the order of all image processing operations in DaVinci Resolve to create many different corrections and effects. The green RGB inputs and outputs are used to connect these nodes together. Each node's thumbnail image shows how the clip looks at that particular stage of the grade, giving you a visual indication of what each node is doing, and small badges below each node show you which specific operations are being applied by that node.
- **RGB Inputs and Outputs:** The green inputs and outputs at the upper right and left of each node are used to connect the RGB image that's output from one node to the RGB input of the next node. For a Corrector node to have an effect, you must connect both its RGB input and its RGB output to neighboring nodes in the tree. Furthermore, every single node in the Node Editor must be connected for a grade to be enabled; having any disconnected node in the node tree disables that grade until it's fully connected.
- **Key Inputs and Outputs:** The blue inputs and outputs at the bottom right and left of each node are used to route the key channel generated by a node's Qualifier or Window controls, or imported via a Matte clip that you previously associated with a clip in the Media page. When you connect the key output of one node to the key input of another, you basically copy the first node's key to the second node. You can also combine the key outputs of multiple nodes in various ways using the Key Mixer node.
- **Node Tree Output:** The RGB output of the last node in a tree must be connected to the green Node Tree output node, which "completes the circuit" of image processing, and passes that correction on to the next stage in the DaVinci Resolve image processing pipeline. If the output is not connected, the node tree is disabled and has no effect on the clip. You can only connect one RGB output at a time to the Node Tree output.
- **Second Source Input (for RED HDRx):** You can access the alternate highlight exposure of RED HDRx media by exposing this optional second Source input. For more information, see "Mulit-Channel RED HDRx Support" in Chapter 143, "Channel Splitting and Image Compositing."
- **Second Source Input (from Fusion page):** You can also create additional sources to route in masks or mattes created in the Fusion page for use as keys in the Color page.
- **Alpha Output:** It's possible to create regions of transparency for compositing directly in DaVinci Resolve by connecting a key output to an optional Alpha output.

> For more information, *see Chapter 144, "Combining Keys and Using Mattes."*

Node Badges and Labels

Nodes appear with various labels and badges to help you identify what each node is contributing to the overall grade. How long a label and how many badges appear depends on the size of each node, as set by the Node Editor's Zoom slider.

Nodes showing the kinds of labeling and badges that are available for identifying what operations each node is performing

- **Node number:** Nodes are numbered in the order in which they appear in the node graph.
- **Adjustment badges:** As you apply various operations within a node, small badges appear underneath the thumbnail that indicate which palettes have been used to adjust that node. How many badges are visible depends on how far in or out you're zoomed into the Node Editor, and whether or not there are Color Space or HDR labels already taking some of this room. At larger node sizes, more badges can appear within the width of the node. Each palette in the Color page has a unique badge. If you apply more operations than a node has area to display, a single "downward arrow" badge appears.
- **Animation badge:** Nodes with animated parameters display a keyframe badge.

Labeling Nodes

Nodes can be labeled to identify a particular node's function in your grade. This can make it easier to revise a grade months later. Node labels are also saved when you save a still, so labels can also make it easier to decipher a saved grade down the road. At each node's default size in the Node Editor, nodes can appear with up to 12 characters of text, although larger nodes can accommodate more text.

To label a node:

1. Right-click a node and choose Change Label.
2. Type the label text you want and press Return.

   The label you entered appears above the node in the Node Editor.

To edit a node's label:

- Once a node has a label, you can change the label at any time by double-clicking it.

Selecting Nodes

The node that's currently selected in the Node Editor is highlighted in orange, and is referred to as the current node. When you adjust any of the parameters or settings in the Color page, you're adjusting parameters within the current node. You can only select one node at a time.

To select a node, making it the current node, do one of the following:

- Click any node in the node graph.
- Choose Color > Nodes > Previous Node (Option-Shift-Semicolon) or Color > Nodes > Next Node (Option-Shift-Apostrophe). When you do this, the last node loops around to the first one, and vice versa.

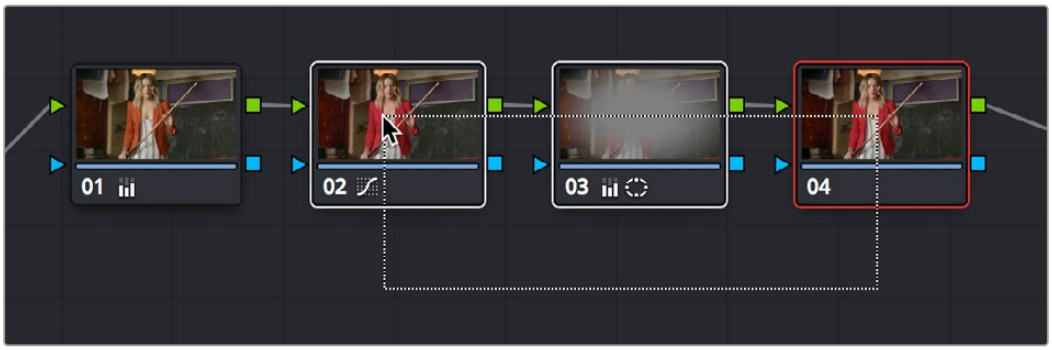
The selected node appears highlighted in orange. You also have the ability to select multiple nodes, in preparation for doing things like moving them or creating compound nodes (covered later in this chapter).

To select multiple nodes:

- Command-click each of the nodes you want to simultaneously select.
- With the Node Editor Selection tool chosen (at the upper left-hand corner of the Node Editor) simply drag to select multiple nodes using a bounding box.

The Node Editor's Selection tool

When you select multiple nodes, each one appears highlighted in white, with the exception of the current node, which remains orange.



Selecting three nodes by dragging a bounding box

When you select another clip in the Timeline, the default behavior is that the last node that was selected when you worked on that clip is the one that's selected when you move to that clip again. However, a setting in the option menu of the Node Editor and the Color panel of the User Preferences, called "Switching clips," lets you change this behavior.

For more information on this option, *see Chapter 4, "System and User Preferences."*

Disabling Nodes

In the process of creating a node tree, it's often useful to turn one or more selected nodes off to disable their effect on your grade. It's also useful to turn the entire node tree off and on in order to see "before and after" views of the current clip. Disabled nodes are not processed during rendering, and they remain disabled when you save that grade along with a still in the Gallery and then apply that grade to another shot.

Disabling Individual Nodes

Disabling a single node is useful for temporarily disabling adjustments that you don't think you want to use but don't want to discard (however you should remember that it's alarmingly easy to inadvertently turn these nodes back on again). It's also good for giving your client a before and after preview of the last adjustment.

To toggle individual nodes off and on, do one of the following:

- Click the number of any node in the node graph to disable that node by itself.
- Select a single node, and choose Color > Nodes > Enable/Disable Selected Nodes (Command-D).

Disabling Multiple Nodes All At Once

If you select more than one node in the node tree, using any of the methods of turning nodes off and on described above (including Command-D) will toggle Enable/Disable Selected Nodes. Please note that the current node outlined in orange is always considered to be part of the selection.

This makes it easy to do before/after comparisons of any combination of nodes doing complicated adjustments by selecting them, while leaving un-selected nodes doing base adjustments that you want to leave enabled alone.

Disabling All Nodes

In addition to the Bypass All Grades command, disabling all nodes of a grade at once is another easy way of disabling a grade to provide a before and after of the original state of the clip (or the color managed state of the clip if Resolve Color Management (RCM) is enabled). More importantly, it's a good way to disable all nodes of a grade in preparation for walking your client through each operation in that grade node by node, as you turn each node on in turn while narrating how it's improving the image.

To turn every node off and on at once, do one of the following:

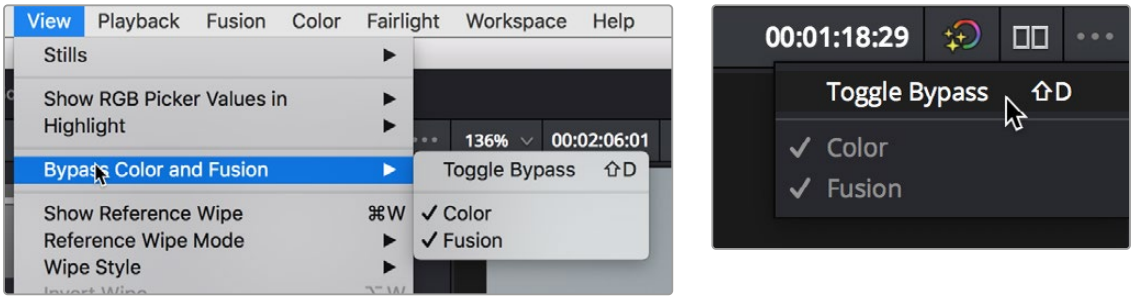
- Choose Color > Nodes > Enable/Disable All Nodes (Option-D) to toggle all nodes off and on.

IMPORTANT: When you turn every node off and then on again, every node is re-enabled, even nodes that had previously been individually disabled.

Turning Grades and/or Fusion Effects Off

The Bypass Color Grades and Fusion Effects button/drop-down commands in the Viewer's title bar are also available via View > Bypass Color and Fusion menu commands. Turning off Fusion effects in the Color page is an easy way to improve playback performance on low power systems when you just need to make a quick set of grading adjustments. Toggling grades off and on is also a convenient way to quickly get a before and after look at a shot where the before goes all the way back to the source.

If you choose Toggle Bypass or click the Viewer control, you'll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.



(Left) Menu commands for bypassing Color and Fusion,
(Right) Edit page Timeline Viewer controls

Resetting Nodes

If you're dissatisfied with your current operations and want to start over, there are three ways you can reset nodes in the Node Editor. These are available as items in the Color menu.

- **Reset Selected Node Grade:** Resets the currently selected node, eliminating all keyframes, to the default parameter settings.
- **Reset Grades and Keep Nodes:** Resets every node in the current node tree, without affecting the node tree's structure; all nodes remain where they were. However, each node has been reset to the default parameter settings.
- **Reset All grades and Nodes:** Deletes every node and keyframe, and restores a single node set to the default parameter settings.

You can also reset nodes using the mouse, which can be a quick thing to do if you're already working in the Node Editor to accomplish other things.

Methods of resetting nodes with the mouse:

- **To reset a selected node:** Right-click that node and choose Reset Node Grade from the contextual menu.
- **To reset all grades and nodes:** Right-click anywhere in the background of the Node Editor, and choose Reset All Grades and Nodes from the contextual menu.

Methods of resetting nodes with the keyboard:

- **To reset a selected node:** Press (Shift-home).
- **To reset all grades and nodes:** Press (Command-home).
- **To reset all grades and keep nodes:** Press (Shift-Command-home).

Previewing and Restoring Node Trees

There are two other methods of quickly dealing with unwanted changes you've made to node trees, without needing to use undo.

- **Preview Memory:** Lets you preview the effect of any saved grade on the current clip. To preview, choose Color > Preview Memory (Option-Shift-P), and then right-click any saved still in the Gallery (or Memory) and choose Add Correction. In fact, you can use Add Correction to try out as many stills as you like. If you like any still's effect, then you can leave it be. If you don't like any of the stills you previewed, then choosing Color > Preview Memory again reverts the clip to the original grade.
- **Original Memory:** This command lets you quickly revert a clip's grade to its original state when you first selected that clip. It is accessed by choosing Color > Original Memory (Option-Shift-O). This is useful for getting immediately back to a clip's original grade if you've made a series of changes that you then regret. Selecting another clip in the Timeline and then reselecting the clip you made changes to resets what is considered to be the current grade.

Caching Specific Nodes to Improve Performance

You can flag specific nodes to be cached, along with all nodes appearing upstream in that node tree. By caching nodes using processor-intensive effects, you free up real time capability for the remaining downstream nodes in a grade. Choosing Playback > Render Cache > User only caches nodes that you've flagged for caching.

When you choose Playback > Render Cache > Smart mode, DaVinci Resolve automatically caches any nodes that use Motion Blur, Noise Reduction, or OFX plugins, without you needing to do anything.

To flag a node and all corrections made in upstream nodes for caching:

- Right-click any node and choose Node Cache > On from the contextual menu.

Editing Node Trees

There is no limit to the number of nodes you can create and connect to one another, and you can make as many or as few parameter adjustments as you like within each node. The following procedures describe the ways you can add nodes to the node graph as you build each grade's node tree.

Adding Nodes

The simplest thing you can do to add to the complexity of a node tree is to add additional nodes, in order to add more adjustments to the current grade. You can add nodes so that they're automatically attached to nodes that are already in the node tree, for immediate adjustment, or you can add unattached nodes to empty areas of the node tree in preparation for assembling a particularly complicated and specific node tree to accomplish a difficult task.

Methods of adding nodes to the tree using a mouse, tablet, or trackpad:

- **To add any kind of node to the node graph using the mouse:** Right-click any node in the node tree, and choose the type of node you want to add from the Add Node submenu of the contextual menu.
- **To add a disconnected node to the node graph:** Right-click anywhere within the node graph's background, then choose Add Node > Corrector from the contextual menu. Disconnected nodes have no effect on a node tree until they're connected.

Methods of adding nodes to a currently selected node in the tree using the keyboard:

- **To add a serial node after the currently selected node:** Press Option-S key, choose Color > Nodes > Add Serial from the menu.
- **To append a serial node to the very end of the node tree:** Press Option-K, choose Color > Nodes > Append Node from the menu.
- **To add a serial node before the currently selected node:** Press Shift-S, or choose Color > Nodes > Add Before Current.
- **To add nodes in parallel to the currently selected node:** Press Option-P, choose Color > Nodes > Add Parallel from the menu.
- **To layer nodes with the currently selected node:** Press Option-L, choose Color > Nodes > Add Layer from the menu.
- **To add an outside node to the currently selected node:** Press Option-O, choose Color > Nodes > Add Outside Node from the menu.

Adding Nodes with Windows Turned On

There are also dedicated commands for adding serial nodes with Circular/Linear/Polygon/Curve windows automatically turned on, for convenience.

To add a node to the tree with a Window automatically enabled:

Choose an item from the Nodes menu that corresponds to the following:

- **Node + CPW:** Circular Power window (Option-C)
- **Node + LPW:** Linear Power window (Option-Q)
- **Node + PPW:** Polygonal Power window (Option-G)
- **Node + PCW:** PowerCurve window (Option-B)

Whenever you add a node to a tree, it's numbered consecutively to come after the next most recent node you'd added, regardless of the order in which it appears in the node tree. For example, if you've already added three nodes, and then you decide to add another node in between Nodes 1 and 2, the new node will be Node 4, and the order of the nodes will be 1, 4, 2, and 3.

Deleting Nodes

If there's a node that you no longer need, you can choose to remove it completely from the node tree to remove its effect permanently.

To delete a node, do one of the following:

- Select a node, then press the Forward-Delete key.
- Right-click a node, and choose Delete Node.

After you've deleted a node, the node to the left and right of the node you deleted are automatically connected so that the node tree is unbroken. Also, all the nodes in a tree are renumbered after the deletion of any node, so there's no discontinuity in node order. For example, if you have three consecutively numbered nodes in a tree and you delete the second one, the node that was formerly number 3 is renumbered to be 2.

Connecting and Disconnecting Nodes

For a node tree to work, every node in the Node Editor must be connected into a working node tree, from the Source input, through each node in the tree, to the Node Tree output. Any disconnected node will result in that clip's grade being disabled. However, you may find the need to disconnect some parts of a node tree in order to reconnect them in different ways.

To connect two disconnected nodes:

- Click and drag a connection from the RGB or key output of one node to the corresponding RGB or key input of another, and when the line highlights, release the mouse button.

To change the connection from one node to another:

- Move the pointer over the second half of any connection line between two nodes until it highlights blue, then click and drag it to reconnect it to another input, on that node or another.

To disconnect two nodes, do one of the following:

- Position the pointer over the right-hand side of a node connection so it highlights, and click it to delete it.
- Click a link to select it (selected links turn orange), and then press the Delete or Forward-Delete key.
- Right-click a link and choose Delete Link.

To overwrite a node's previous connection:

- You can drag a connection to a node input or output that's already connected, which will overwrite the previous connection with the new one you're dragging. When you do this, the connection that's about to be overwritten appears highlighted in orange.
- You can connect any node's RGB or Key output to as many inputs as you want, but you can only have one connection going to a node's input. The exception to this is a node with multiple inputs, designed to combine the output of multiple nodes. These include the Parallel, Mixer, and Key Mixer nodes.

Extracting a Node

Sometimes you need to remove a node from its current position in the node tree, such that the nodes to the left and right of it automatically reconnect to one another, saving you from having to reconnect them manually. This is called extracting a node.

To extract a node, do one of the following:

- Select a node, and choose Color > Nodes > Extract Current Node.
- Select a node, and press E.

Keep in mind that disconnected nodes in the node tree suspend grading altogether, so you'll want to either reconnect that node to another part of the node tree, or delete it; you cannot leave it disconnected in the Node Editor.

Inserting a Node

If there's a disconnected node in the Node Editor, there's a simple way you can insert it into the node tree between any two other nodes. This also works for nodes that you're dragging into a node tree from another source, for example, from the exposed node tree of a still in the Gallery.

To insert a disconnected node between two other nodes:

- Drag a disconnected node, or a node from another node tree, onto the connection between any two other nodes in a node tree; when a plus icon appears over the node you're dragging, drop it to insert the node.

Rearranging Node Order

The order in which nodes are connected in your tree affects the result of a grade. For example, if you boost the highlights in the first node, and then you try to isolate a portion of the picture in a second node that you now realize has been clipped, you may to need to change your order of operations to optimize your corrections.

To swap the contents of two nodes:

- Command-drag any node and drop it onto another node to swap the operations within each node. The nodes won't appear to have moved, but you should be able to tell from the node badges underneath that the operations have been reversed.

To move a node to any other position in the node tree:

1. Double-click any node in the node tree and press E to extract it, removing it from the tree so that it becomes unattached.
2. Drag the now-unattached node to the connection line between any two other nodes in the tree, and when a small plus icon appears, drop it to automatically connect that node at that position in the node tree.

Copying and Pasting All Settings From One Node to Another

The simplest thing you can do is to copy all of a node's settings and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip's grade.

To copy a node's settings from one clip to another, do one of the following:

- Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.
- Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, or create a new node, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

NOTE: There are additional methods of copying nodes and individual node settings.

For more information, *see Chapter 140, "Grade Management."*

Node Context Menu Actions Can Have Assigned Shortcut Keys

You can assign shortcut keys to common Node Context menu actions like Lock Node, HDR Mode, Clean Up Selected Node Graph, etc. Go to Keyboard Customization > Commands > Panels > Color Nodes to assign the shortcuts.

Keeping Node Trees Organized

It's a good idea to keep the arrangement of your nodes in the node graph clean and neat. It'll make it easier to read your tree if you need to revisit a grade later on, and it will also make it easier for other colorists working on the same project to figure out what you're doing. The following procedures describe how to rearrange the nodes in your tree, and the node tree working area, to help you keep on top of your grades.

To move nodes within the Node Editor:

- Drag any node to a new position.
- Command-click or drag a bounding box around multiple nodes that you want to move, and drag them all to a new position.

Of course, it's easy to get carried away. If you've been working furiously on a complex grade and you find yourself staring at a riot of disorganized nodes, it's easy to quickly reorganize your node graph using a pair of commands in the Node Editor contextual menu.

To clean up the node graph, right-click the Node Editor and choose:

- **Cleanup Node Graph:** Moves all nodes in the node graph so they appear in an evenly spaced grid. Connection lines are routed around nodes to minimize clutter.

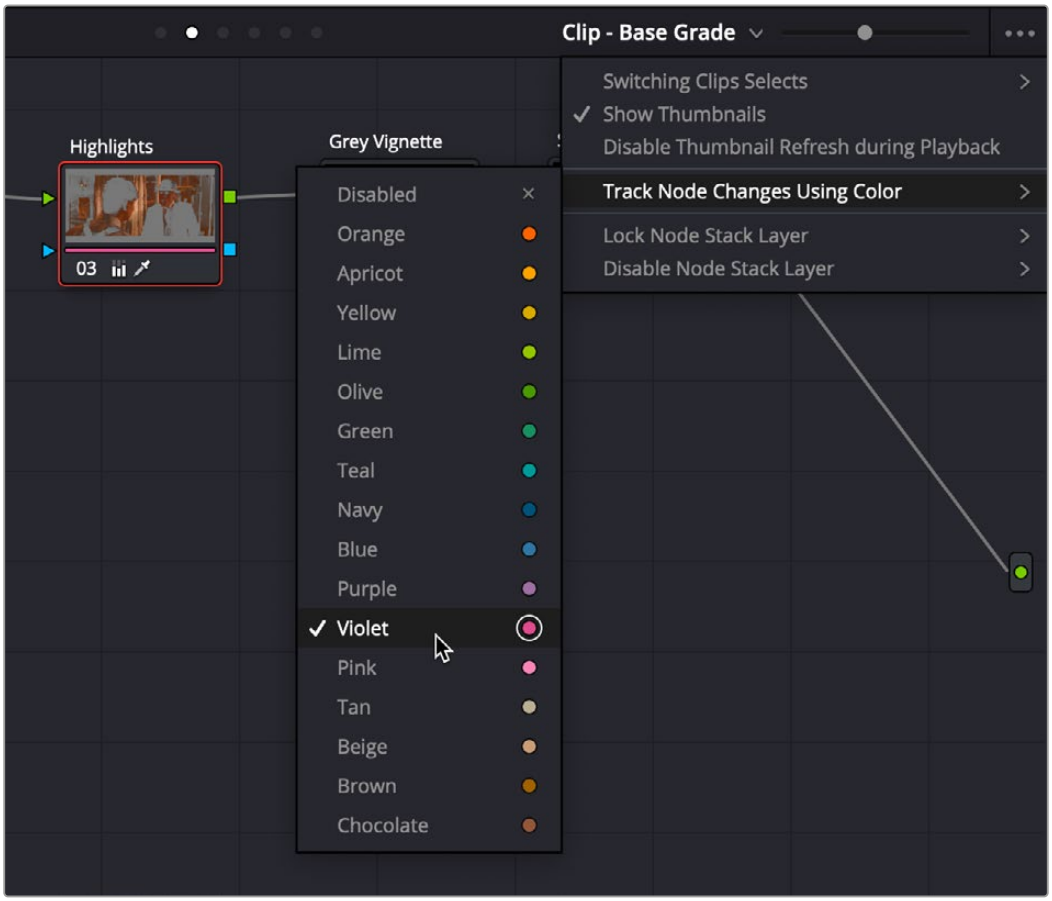
Before/after using “Cleanup Node Graph”

If your grading has gotten only slightly out of control, you can use the Cleanup Node Graph command on multiple clips at the same time. To do so, select the clips whose node graphs you want to tidy up in the thumbnail timeline, then right-click in on of their node graphs and choose “Cleanup Selected Node Graphs” from the drop-down menu. This will perform a Cleanup Node Graph operation on all selected clips at the same time.

Track Node Changes Using Color

The Color Page node graph (3-dot) option menu has an option to Track Node Changes Using Color. This is a per system setting where the you choose the node color you want to apply to newly created or modified nodes.

In a multi-user collaboration environment, each colorist can set their own preassigned node color. Then, based on the node color, you can easily know who last modified a specific node. In single user scenarios, this feature can be used to track changed nodes and grades after a particular point in time, such as a client review session.



Selecting Track Node Changes Using Color from the Node Graph option menu will subsequently change the color bar on a node after any modification made to that node. In this case, the Highlights node's color bar is now Violet after the Violet user has made a change to it.

Additionally, you can filter timeline clips by their node colors as well. To do this simply click the Down Arrow in the Clips tab, hover over Node Color, and select the color you wish to filter by clicking on it. You can repeat this process to filter multiple colors.

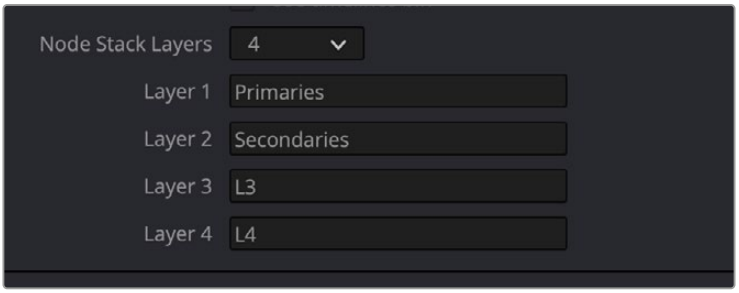
When set, only the clips that have the selected node colors will appear in the timeline.

Using Node Stack Layers

Node Stack Layers allow the management of complex grading workflows by creating multiple sequential node graphs that let you break up grades into separate sections. This allows users to isolate related functions like stabilization, corrections, hero grades, and display trims into individual node layers.

Grade operations like ripple, reset, and editing can also be done on a per-layer basis. When you grab a still to the Gallery, all of the Node Stack Layers are saved as part of that still.

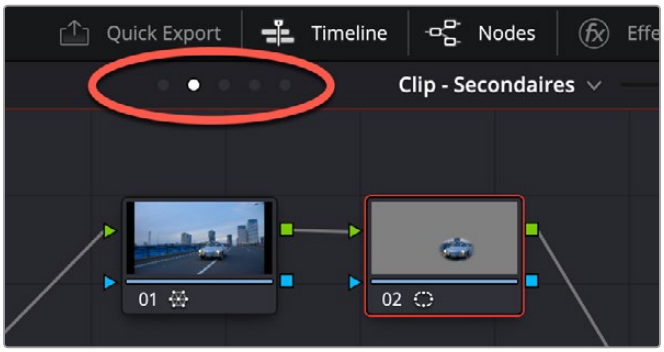
Since Node Stack Layers are applied sequentially (in order from lowest to highest), you can also use them as highly customizable re-usable filters for your grades.



The Node Stack Layers number and naming options in the Project Settings

From Project Settings > General Options > Node Stack Layer Count, users can set the number of clip node layers. You can also add custom names to the layers such as “primaries,” “secondaries,” “finishers,” etc.

NOTE: If for some reason you return to the settings and lower the amount of node stack layers later, all the grades in those layers are removed across your entire project. To get them back, simply add the layer numbers back in.



The Node Stack Layer is navigated by clicking on the dots above the node graph or selecting the name of the active layer from the drop-down menu to the right.

Users can then select individual layers from the navigation dots above the node graph or from the layer drop-down menu to the right.

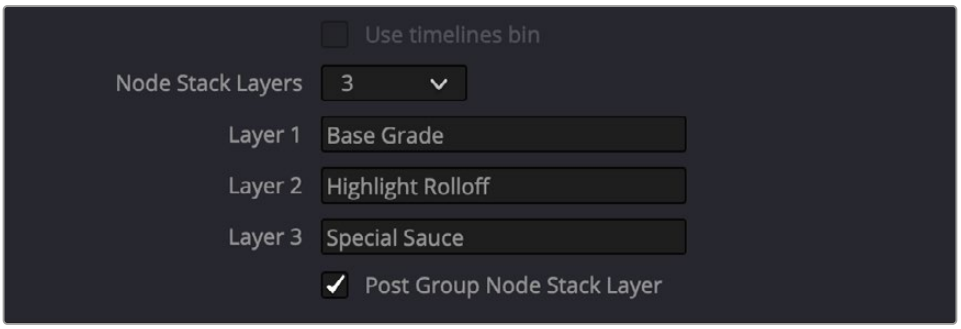
IMPORTANT: All node layers are applied sequentially to the clip: pre-clip, L1, L2, L3, L4, post-clip, and then Timeline.

Copying Node Stack Layers

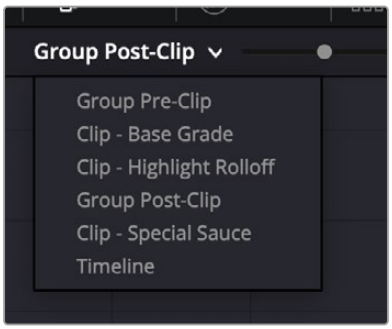
You can copy (not just apply) the Active Node Stack layer from a Timeline Clip in the Gallery. To do so, right-click on a Timeline Clip in the Gallery and select Copy Active Layer.

Post Group Node Stack Layer

In Project Settings under General Options > Color, there is a checkbox called Post Group Node Stack Layer. When you enable this checkbox, the last node stack layer is processed after the Group Post-Clip node graph. This function allows you to dedicate the last node stack layer for post group grades and transforms.



Checking the Post Group Node Stack Layer box in Project Settings > Color.



The revised node stack order now processes Layer 3 Special Sauce after the Group Post-Clip layer (that is automatically generated when you group clips). Normally the Group Post-Clip layer would be last.

Using Compound Nodes

Another node structure you can use to keep complex node trees organized is the compound node. You can Command-click to select any number of nodes in the node tree (selected nodes are highlighted white), and then use the “Create Compound Node” command to nest all selected nodes inside of a single node.

Before/after creating a compound node

The resulting compound node that’s created has as many inputs and outputs as are necessary to accommodate the connection lines that attached the nodes you selected to the rest of the node tree.

You can use compound nodes to organize complicated node trees by nesting sets of nodes that work together to do a specific thing within a single node. You can also turn a set of nodes that you’re using to create a specific effect into a compound node in preparation for saving to the Gallery. Creating a library of effects in this way makes it easy to reuse them via the Append Grade command, without the undue burden of adding lots more nodes to your grade later on.

Methods for creating and working with compound nodes:

- **To create a compound node:** Command-click each node you want to nest inside of a compound node to select them with a white highlight, or drag a bounding box around a group of nodes. Then, right-click one of the selected nodes, and choose Create Compound Node from the contextual menu.
- **To edit a compound node:** Either double-click the compound node you want to open or right-click any compound node and choose Show Compound Node from the contextual menu. The contents of that node appear in the Node Editor, taking the place of the overall node tree.

- **To exit a compound node you're editing:** To return to the top level node tree, double-click the leftmost item in the path control at the bottom of the Node Editor, or click the name of the compound node. You can also right-click in the compound Node Editor and choose "Exit Compound Node" from the contextual menu.
- **To label a compound node:** Right-click a compound node, choose Change Label from the contextual menu, and type a new label for that node. Press the Return key when you're finished.
- **To decompose a compound node:** Right-click the compound node you want to decompose, and choose "Decompose Compound Node" from the contextual menu. The compound node disappears, replaced by the original nodes within. Please note, if you had applied an adjustment to the compound node itself, that adjustment is lost when you decompose it back into its constituent nodes. If you want to preserve the compound node adjustment itself, you can copy it, then decompose the node, and then create a new node and paste the adjustment you'd copied.

Adding Inputs and Outputs to Compound Nodes

When you open the contents of a compound node using the Show Compound Node command, you can make whatever adjustments you like to the node tree within, but you also have the option of right-clicking within the Node Editor and choosing Add Source to add an input to the compound node, or Add Output to add an output. Adding more inputs and outputs lets you set up the node to connect to the rest of your node tree in more complicated ways. Disconnected inputs and outputs have no effect on your grade.

Furthermore, you can also use the Add Alpha Source and Add Alpha Output contextual menu commands to add KEY inputs and outputs to a compound node, making it easy to route key or alpha channel data to other connections in the enclosing node tree.

Nesting Compound Nodes

Compound nodes can also be nested within other compound nodes, if necessary.

Grading Compound Nodes

After you've created a compound node, you can select it to make one or more adjustments using the compound node itself, which effectively adds those adjustments after all other adjustments that take place via the nodes that are inside of the compound node. This gives you the opportunity to "trim" the effect that compound node is having on your grade, or to limit it using a qualifier or window.

To adjust the individual nodes nested within a compound node, you need to first open the compound node. Then, you can select and adjust any node as you ordinarily would.

Identifying Nodes

As you make various adjustments to nodes, small badges appear underneath that indicate what each node is actually doing. Since nodes are capable of holding multiple adjustments, any given node may have multiple badges; how many badges a node can show depends on the zoom level of the Node Editor. Larger nodes will show more badges, whereas smaller nodes will show fewer badges, hiding whichever badges don't fit.

Another nice organizational feature of the Node Editor is an automatic tooltip that appears whenever you hover the pointer over a particular node, that shows you a concise list of all the operations applied to that particular node.

(Left) Badges underneath each node indicate which adjustments it contains.
(Right) Using a node's contextual menu to put that node into HDR mode

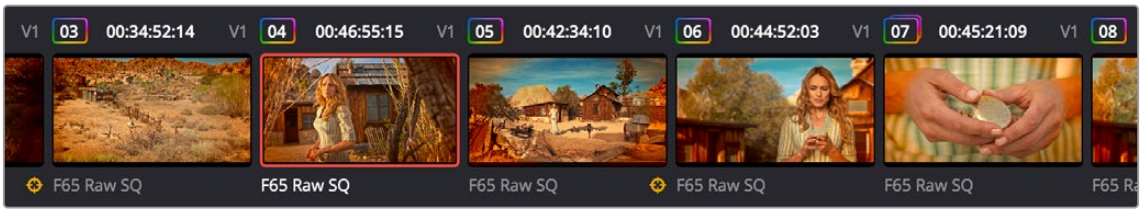
Putting Nodes into HDR Mode

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you're working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu.

This setting adapts that node's controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.

Clip vs. Timeline Grading

Ordinarily, the Node Editor has two modes. The default Clip mode lets you create individual grades for each clip or group in the Timeline. However, the Timeline grade mode lets you apply a single grade simultaneously to every clip in the Timeline, as seen in the Thumbnail timeline in the following screenshot.



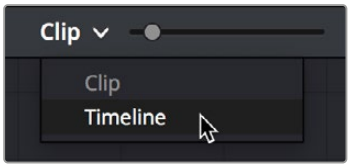
A paragon of sophisticated grading, the author applies a red edge vignette to every clip in the project simultaneously using the Timeline grade

There are a variety of reasons you might want to do this. For example, if you're working on a commercial spot, you might elect to use Clip grades to do general correcting and scene-to-scene balancing, and then use the Timeline grade to apply a single stylistic grade to the entire spot simultaneously. That way, any changes the client wants made to the style of the grade can be instantly applied to the whole spot.

Another example would be using the Timeline grade to apply corrections meant to address QC issues running throughout a program, desaturating highlights or selectively darkening a specific shade of red wherever it appears.

To switch between Clip and Timeline grading modes:

- Choose the mode from the drop-down menu at the top right of the Node Editor.



Selecting Track mode in the Node Editor

- Click the dot in the Node Editor toolbar that corresponds to the Clip or Timeline mode

Two dots show whether you're in Clip or Timeline mode; these can be clicked to switch

NOTE: When you reset the Timeline grade using the Color > Reset All Grades and Nodes command, the Output Sizing parameters are reset as well.

Two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you're working on a clip that's part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well.

For more information about group grading, *see Chapter 140, "Grade Management."*

Timeline Grades and Saved Stills

When you save a Gallery still, the Clip and Timeline grades are both saved. However, when you apply a grade from that still, you only apply either the Clip grade, or the Timeline grade, depending on which mode the Node Editor is in.

For more information on saving and applying grades, *see Chapter 141, "Node Editing Basics."*

Chapter 142

Image Processing Order of Operations

The addition of the HDR palette and Color Warper in DaVinci Resolve 17 necessitated an updated diagram of the order of all image processing operations in DaVinci Resolve, from input through output.

A truly detailed breakdown now requires two charts as detailed in this chapter; the first chart details the overall order of operations taking place on every page, while the second zooms into the specific order of operations occurring within each node of the Pre-Clip, Clip, Post-Clip, and Timeline grades that you create on the Color page. Understanding the order of operations presented here will make it easier for you to control the power of the full DaVinci Resolve toolset.

Contents

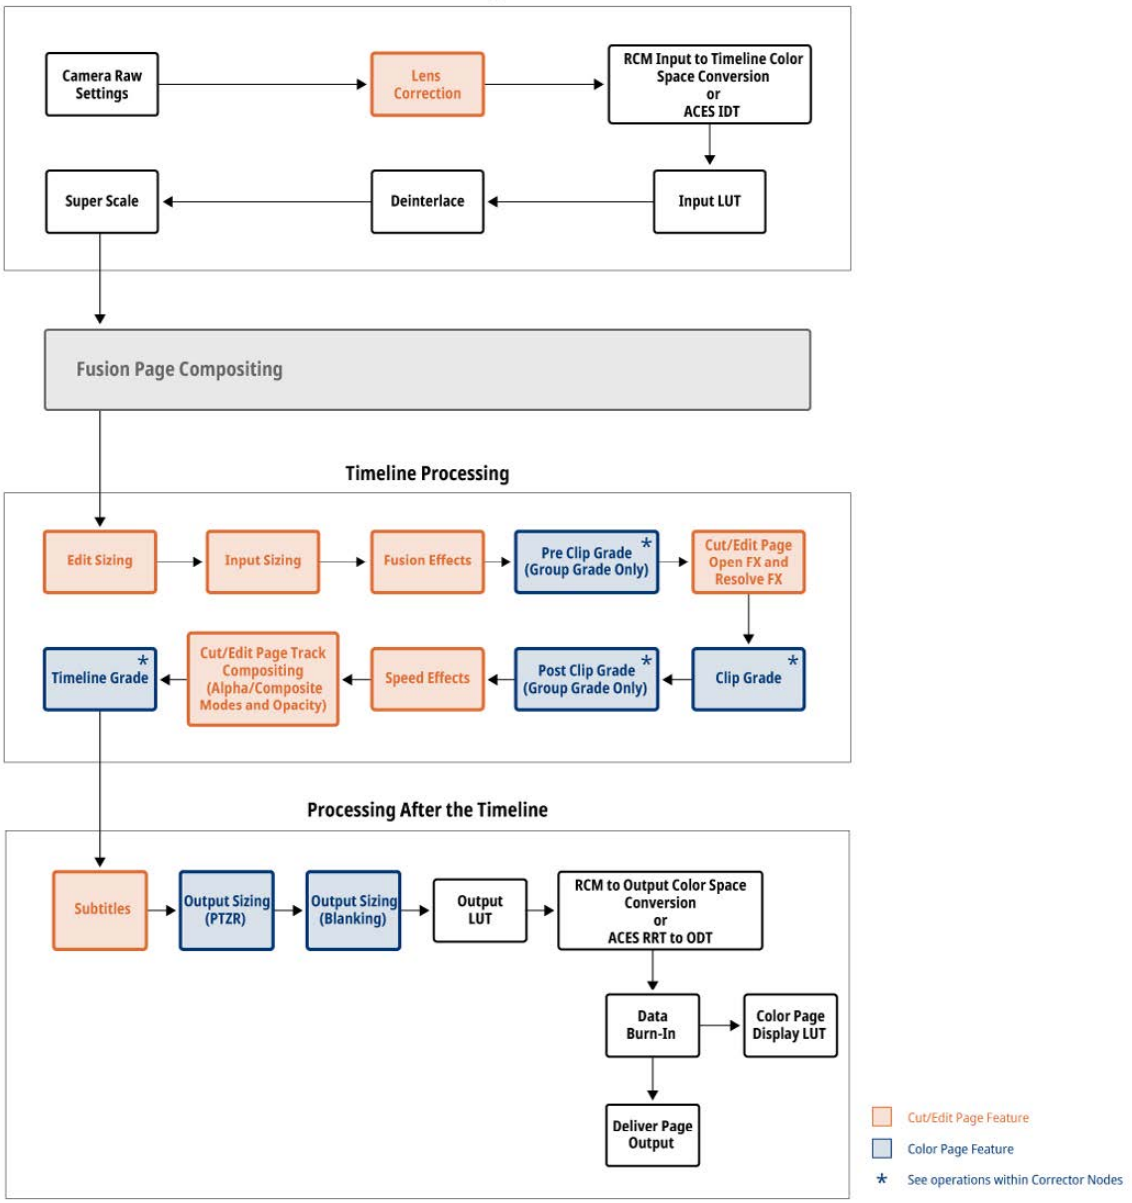
Overall Image Processing 3177

Image Processing Within Grades 3178

Overall Image Processing

In the following chart, each image processing operation in DaVinci Resolve is shown in the order in which it's processed. Operations are color-coded to indicate the page on which those controls appear, because in many cases page order does not determine image processing order. Why? Either to make sure each operation is processed as cleanly as possible, or to give the user the maximum control over the image. For both of these reasons, image processing order is carefully considered, and in some cases the best result requires operations on different pages to alternate with one another.

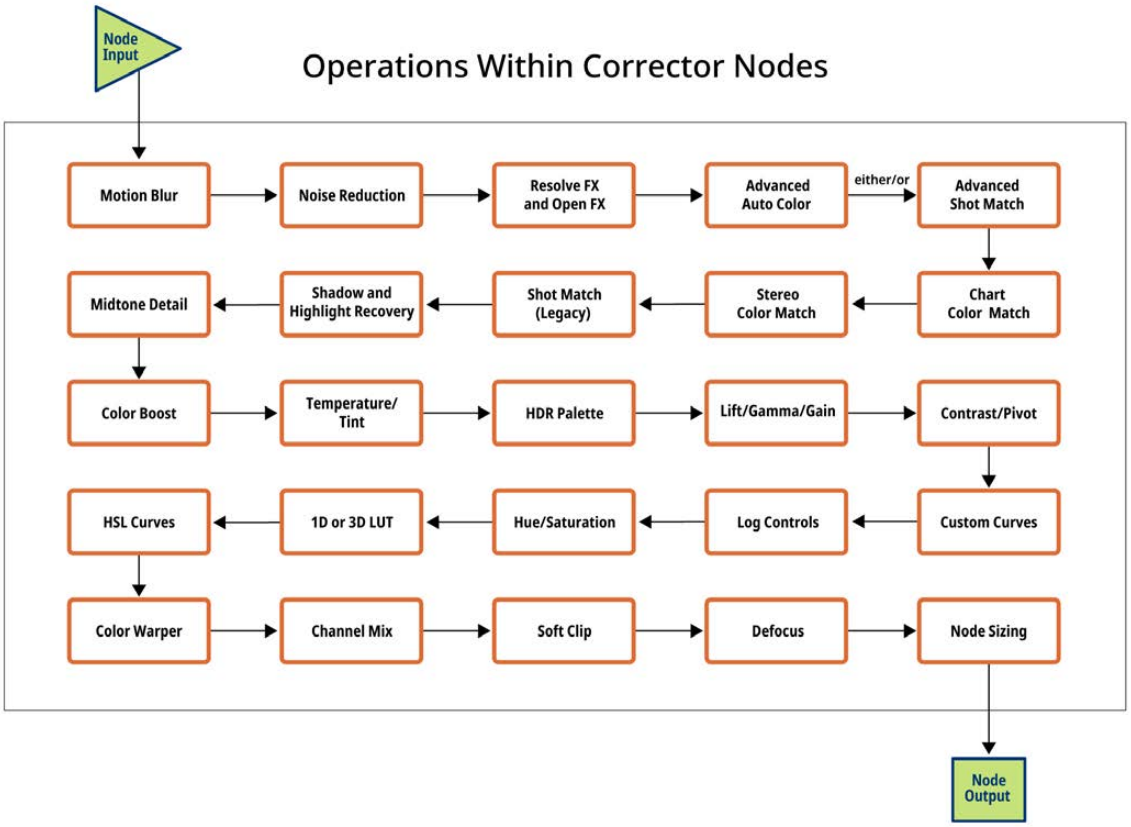
Most of the time, this order of operations is irrelevant to the user who's only interested in the end result. However, if you're trying to achieve something very specific, or if you're wondering why you see a particular result when you use the features of the Cut, Edit, Fusion, and Color pages together all at once, this chart should help make things clear. Finishing artists in particular should find this chart illuminating.



The overall order of image processing operations in DaVinci Resolve, from input through output

Image Processing Within Grades

For Pre-Clip, Clip, Post-Clip, and Timeline grades on the Color page, most Color page operations are available within each Corrector node you add to the Node Editor. Within each node, these operations take place in the following specific order.



The order of image processing operations that takes place within each Corrector node in the Color page

Thanks to the modular operation of the Node Editor, if a pair of image processing operations you need to use isn't in the ideal order for what you're trying to do, you can apply each operation using two different nodes in order to force those operations into the order you want. Similarly, when using Layer, Parallel, or Key mixer nodes, the order of operations can be seen in the visible arrangement of nodes in your node graph.

That said, most colorists tend to spread different operations across multiple nodes, whether they need to or not, for organizational purposes or to "sandbox" certain volatile decisions that might need to be independently revised later. However, nothing's keeping you from using multiple operations within a single node if you prefer a simpler node structure for your grading. Thanks to the flexibility of the Color page, it's your choice.

Chapter 143

Serial, Parallel, and Layer Nodes

This chapter covers the four fundamental node structures you can use to combine Color page adjustments in even more detailed ways. These methods let you control your order of operations and re-combine multiple versions of the graded image in much more specific ways.

Contents

Serial, Parallel, and Layer Node Tree Structures 3180

Layer Mixer Prioritization 3183
Using Composite Modes With the Layer Mixer 3184
Adjusting Layer Node Strength Using Key Output Gain 3185
Converting Layer Mixers to Parallel Mixers 3186

Serial, Parallel, and Layer Node Tree Structures

There are several ways you can organize nodes in a tree. Each method lets you control a group of image processing operations in different ways to achieve specific results. This section covers how to use Serial nodes, Parallel nodes, and Layer nodes, as well as how to use LUTs, work with HDR media that lets you combine two different exposures using two different Source inputs, and apply additional project-wide adjustments using the Timeline grade.

Serial Node Structures

The simplest, and most common node structure is a serial cascade of nodes, where a linear series of nodes is connected, one after another.

Serial nodes, where the output of one node feeds an altered image to the next

Much of the time, this method of constructing a tree of multiple operations is all you need to do. It's a simple and intuitive way of organizing your adjustments, similar in principle to the stacks of layers used in other grading and compositing applications to apply multiple operations to a clip.

Controlling What Feeds a Node's RGB Input

When you create a grade using serially arranged nodes, each node's output is used as the next node's input, so the order in which the nodes are arranged determines the order of image processing operations.

In the following screenshot, the node tree shows a series of three operations that are applied to a log-exposed, low-contrast clip. The first node expands clip contrast and increases saturation. The second node isolates the sky to intensify its color. The third desaturates and warms the image. At right, you can see the result of this node tree.

Node 2 pulls a clean key from the image data fed it by Node 1

If, instead, we reversed the order of Nodes 2 and 3, the result will be a less effective key.

By comparison, Node 3 pulls a less then optimal key from the image data fed it by Node 2

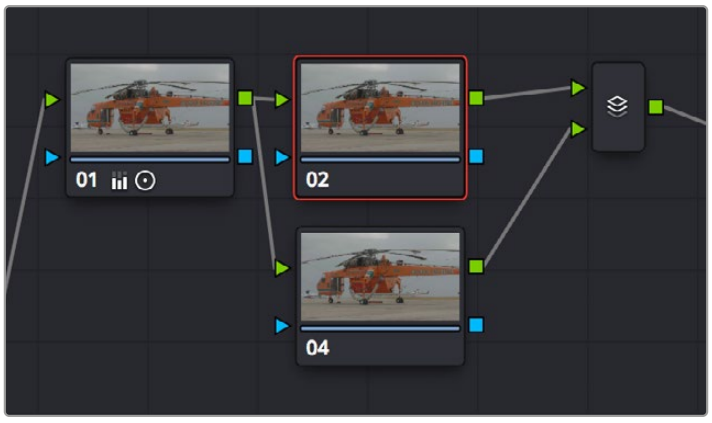
Because the secondary operation is sampling the desaturated image, rather than the source, the HSL Qualifier's key has less image data to work with, and thus you may get an inferior result.

Parallel Node Structures

Another way to organize your corrections is to use a Parallel node structure, which lets you apply two or more overlapping adjustments at a single stage of a node tree. You can use the Parallel node structure for organizational reasons when there is a group of secondary corrections that you want to apply all at once. You can also use this structure for the unique way it blends overlapping image adjustments.

The Parallel Mixer node that makes this possible has multiple RGB inputs and a single RGB output. This lets the Parallel Mixer mix together multiple Corrector nodes, outputting a single image as a result.

When you add a Parallel node to an existing node, DaVinci Resolve automatically adds one Corrector node below the current node, and adds a Parallel Mixer node to its output.



Adding a Parallel node to Node 2 automatically adds the Parallel Mixer

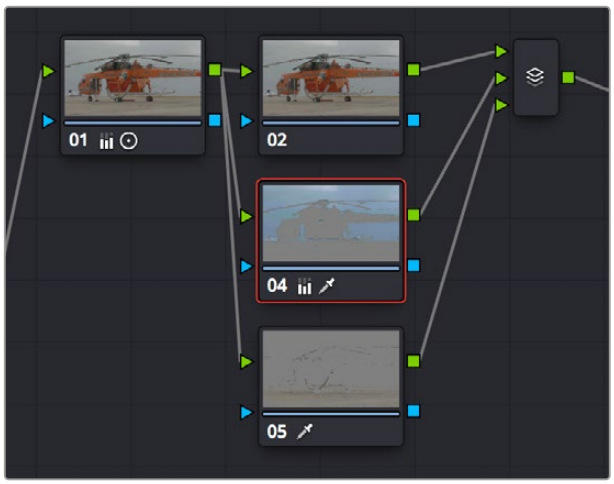
TIP: If you want to create a series of Parallel nodes that connect to the output of the currently selected node, create a Serial node before you create your first Parallel node.

If you're manually connecting another node to a Parallel Mixer node, you can drag from the output of the node to the Parallel Mixer node, and it will automatically add an input for you.

To create an additional, unconnected input on a Parallel Mixer node:

- Right-click a Parallel Mixer node and choose Add One Input.

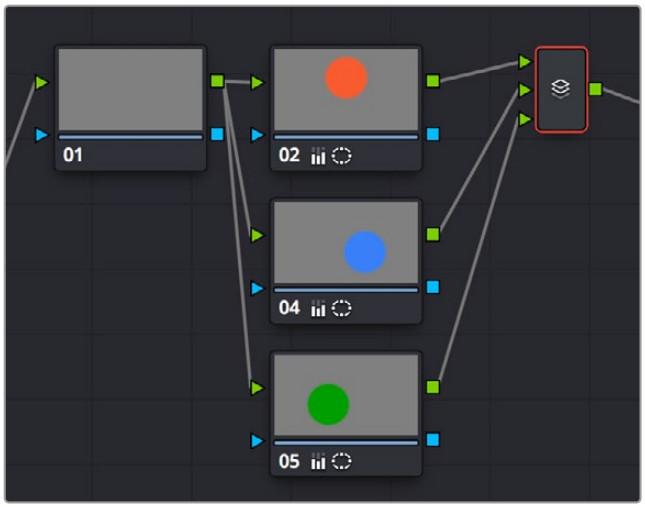
Ordinarily, the RGB input of every Corrector node that's connected to a Parallel node is connected to the output of the same node. This results in a stack of nodes that take the same state of the image as their input. This makes it easy to apply multiple secondary operations without worrying about whether or not a change to one will affect the keys of the others.



Further Parallel nodes can be added as you wish with each using a common source

If you add another node in parallel, the Parallel Mixer automatically adds another input. You can have as many nodes in parallel as you need.

The adjustments made by all nodes that are connected to a Parallel Mixer are combined equally, regardless of which nodes are highest. In the following example, a separate overlapping window is applied by each of three nodes in parallel.



The Parallel Mixer blends all input nodes together

As you can see in the image at right, the three tints created by the overlapping windows are all mixed together equally; the colors blend with one another as if they are optically mixed. Most of the time, this is exactly what you want when you're blending overlapping naturalistic color adjustments.

Converting Parallel Mixers to Layer Mixers

On the other hand, if you need your overlapping color adjustments to have priority over one another, or if you want to combine multiple adjustments using composite modes, then you may want to use the Layer Mixer node instead. If you've created a Parallel Mixer structure and you want to convert it to a Layer Mixer, you can.

To change a Parallel Mixer node into a Layer Mixer node:

- Right-click a Parallel Mixer node and choose Morph Into Layer Mixer Node.

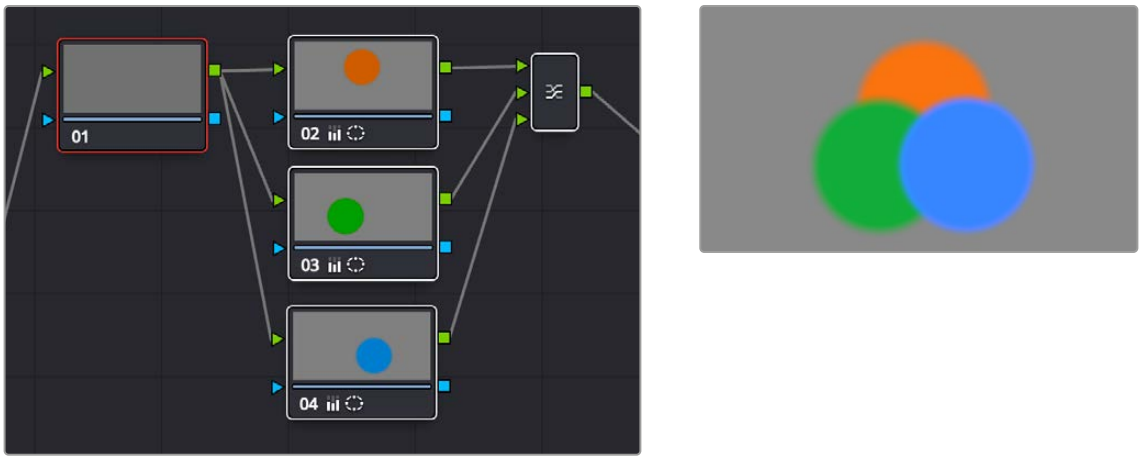
Layer Mixer Node Structures

The Layer Mixer is structurally quite similar to the layout used by the Parallel Mixer. However, there are two key differences. First, the Layer Mixer node combines multiple adjustments with priority given to the image adjustment in the lowest overlapping node input. Second, you have the option of combining all of the Corrector nodes that are connected to a Layer Mixer using one of several different composite modes, to create a wide variety of visual effects.

Because of their similarities, layering nodes with the Layer Mixer works in much the same way as creating a Parallel node structure.

Layer Mixer Prioritization

In the following example, the same node structure from the Parallel Mixer example is shown, this time with the three overlapping color adjustments mixed together using the Layer Mixer.

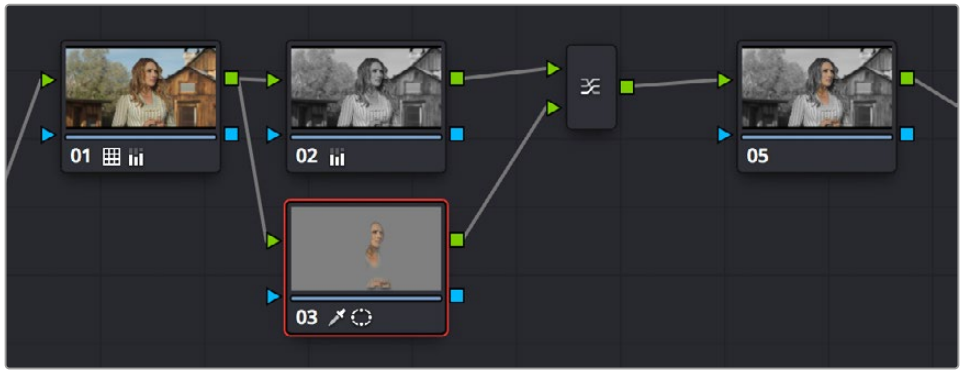


The Layer Mixer prioritizes nodes connected to lower inputs such that each node's output completely obscures whatever is behind it

Now, instead of the three adjusted color tints being blended, you can see that the blue tint, which is connected to the lowest input of the Layer Mixer, is dominant and covers the overlapping regions of the two other adjustments. Meanwhile, the green tint, which is connected to the middle input of the Layer Mixer, covers the overlapping portion of the orange tint, which is connected to the highest input of the Layer Mixer.

Rearranging which connections are attached to which Layer Mixer inputs changes each node's priority, and like the Parallel Mixer, you can add more inputs manually, or by dragging the output of a node to the Layer Mixer.

The Layer Mixer's prioritization is most useful when you have an overlapping adjustment that you need to override any other adjustments happening on that stack. In the following example, two nodes are connected to the Layer Mixer node. Node 2 is applying a high-contrast, cool look to the entire clip. Node 3 isolates the skin tone, which is unflattering with the background stylization, and applies a different, more naturalistic adjustment.



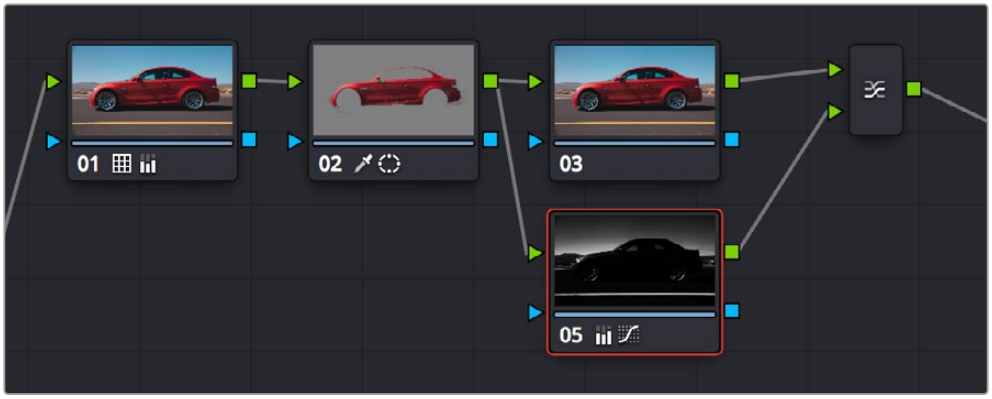
Using the layer mixer, grades on Node 3 will have a greater priority over Node 2, so the final grade combinues the high contrast from Node 2 with the adjusted skin tone from Node 4

Because of the Layer Mixer's prioritization, the adjustment made to the woman's skin tone completely covers the adjustment made to the node that comes above it, providing the best of both worlds with one simple adjustment.

Using Composite Modes With the Layer Mixer

You have the option of combining the adjustments made by all nodes connected to a Layer Mixer node using the same Composite modes that are available when compositing clips in the Timeline. This lets you combine different overlapping image adjustments using compositing math to achieve creative effects or utilitarian fixes.

The following simple example shows two overlapping Corrector nodes connected to a Layer Mixer node that's set to the Add composite mode. Node 3 has no adjustment, but Node 5 has an extremely high-contrast curve adjustment applied, along with a blur, that effectively isolates the highlights of the image and feathers them out.



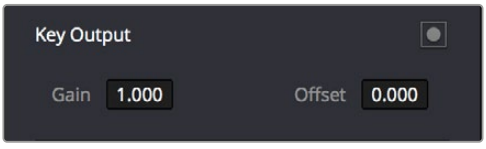
Combining two nodes using the Layer Mixer set to Add to create a glowing effect

By adding both treatments together, a hot glow has been created, blowing out the highlights of the image. Many, many other effects are possible using the different composite modes that are available.

For more information on composite modes, *see Chapter 50, "Compositing and Transforms in the Timeline."*

Adjusting Layer Node Strength Using Key Output Gain

Whether you're combining overlapping corrections, or mixing different adjustments using Composite modes, you'll run into situations where you want to reduce the influence of one overlapping adjustment relative to the other nodes that are connected to the Layer Mixer node. This can be accomplished using each overlapping node's Key Output Gain parameter, located in the Key palette.



Using the Output Gain parameter in the Key palette

Key Output Gain defaults to 1.00, but lowering this value reduces the strength of that node's contribution to the Layer Mixer. Using the previous example, selecting Node 4 (the high-contrast image used to create the glow), opening the Key palette, and reducing the Key Output Gain parameter to 0.50 reduces the intensity of the Glow effect by half.

You can use Key Output Gain to mix the proportion of any number of overlapping adjustments in order to create the perfect combination for your purposes.

TIP: You can also use the Key Output Gain parameter to mix the proportion of adjustments being combined using the Parallel Mixer node.

Converting Layer Mixers to Parallel Mixers

You can easily convert a Layer Mixer to a Parallel Mixer should you discover that you need to mix your overlapping corrections evenly rather than combine them with priority. Keep in mind that you'll lose the ability to use Composite modes.

To change a Layer Mixer node into a Parallel Mixer node:

- Right-click a Parallel Mixer node and choose Morph Into Parallel Node.

Chapter 144

Combining Keys and Using Mattes

A key is the actual image channel that's generated by different secondary operations to isolate specific portions of images to work on.

This chapter covers different ways you can manipulate and combine keys from multiple nodes, or propagate keys among nodes. It also shows different ways you can use mattes that are imported from other applications, as well as how to use the Key palette to further manipulate keys in different ways.

Introduction to Manipulating and Combining Keys

Each node's key input and key output makes it possible to route key channel data from one node to another so you can apply isolated corrections. Furthermore, the Key Mixer lets you combine a variety of keys from different nodes to create more detailed keys with which to tackle complex operations. This section covers all the ways you can recombine key data, as well as how keys can be used in conjunction with the Alpha output to create regions of transparency in a clip for compositing right within DaVinci Resolve.

Outside Nodes

Whenever you use a Power Window or HSL Qualifier to limit a correction within one node, a special node structure lets you automatically create a second node, called an Outside node, to apply additional adjustments to the inverse of the region you isolated in the previous node. Outside nodes are really just Corrector nodes with the Key Palette's Key Input Invert control enabled, which makes it easy to apply separate corrections to an isolated subject and to its surroundings.

The Key Input Invert button, in the Key palette, that inverts any key fed to that node's Key Input

In the following example, the sky has been isolated using a Power Window, and an Outside node has been added to make an additional correction to everything else within the shot.

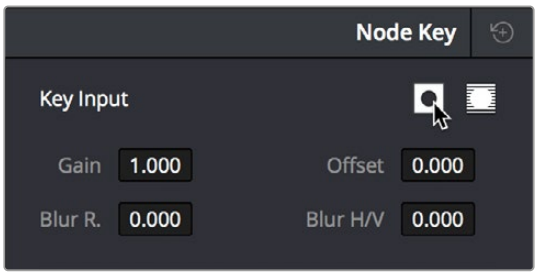
The Outside node automatically has its key input inverted.

To add an Outside node to a node, creating a secondary correction:

1. Select a node that has been limited using a Power Window or HSL Qualifier.
2. Do one of the following:
   - Choose Nodes > Add Outside (Option-O).
   - Right-click a node choose Add Outside Node.

A new node is created immediately after the selected node, with the RGB and key outputs of the first node automatically connected to those of the new node.

When selecting the new node and opening the Key palette, you can see that the Key Input's Invert control is on by default, which is what inverts the key from the previous node.



The Key Input Invert control is on by default for each node.

If, instead of using the Outside node to invert the incoming key, you want to copy the existing key in order to perform another operation to the same isolated region, you can disable the key input's Invert control.

Feeding Keys From One Node to Another

One of the most powerful aspects of the Node Editor is the ability to create keys based on a specific part of the node tree, and feed the result into a completely different correction somewhere else in the node tree. This is one of the reasons for the separate key input and output on every Corrector node.

The key that's created whenever you use the HSL Qualifier, create one or more windows, or use an external matte can be output from one node's key output and fed to the key input of any other node in a tree. There are many reasons to do this, but the following example shows a common problem you can solve with this technique.

Using a key from one node to make an adjustment with a different node:

1. Use Node 1 to apply a basic primary correction, increasing contrast and balancing the color to achieve a pleasing ambient color temperature.
2. Add a Serial node (Node 2), followed by a Layer Mixer node which also adds Node 4 (as seen in the following screenshots). Then, completely desaturate Node 4 and add contrast to make it super-high contrast black and white, desaturate Node 2 just a bit, and right-click the Layer Mixer node to choose the Overlay blend mode with which to combine these two layers.

A group of nodes to create a stylized image

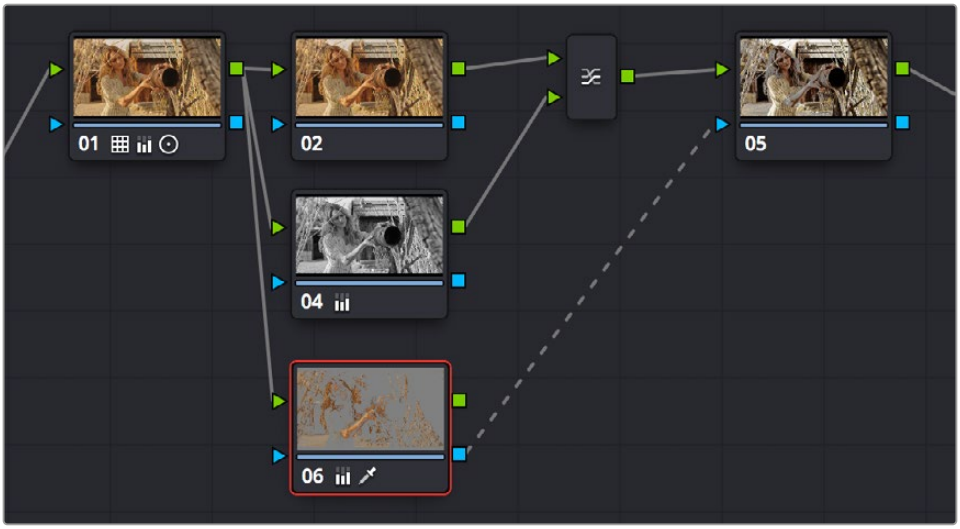
The result is a highly stylized image, but the skin tone on the actor's face and hands in the resulting image are too monochromatic, and you want to give them some differentiation. Simply adding another node after the Layer Mixer and keying the skin tone may not work well because the low level of saturation will make a key difficult to pull.

The resulting stylized image may be difficult to key accurately.

3 Add another node after the Layer Mixer (Node 5 in the screenshot), and then right-click in the gray background area of the Node Editor, and choose Add Node > Corrector to create an unattached node, (Node 6).

4 Connect the RGB output of Node 1 to the RGB input of Node 6, and then connect the key output of Node 6 to the key input of Node 5. Now you're ready to pull a high-quality key from the very first correction in Node 1, skipping all the complication coming afterwards.

5 Use the HSL Qualifier in Node 6 to pull a good strong skin tone key based on the primary image. Given the way the node tree is now set up, that key is fed to Node 5, and will limit whatever adjustments you make there.



Using Node 6 to pull a key from the image output by Node 1, and feeding that key to Node 5

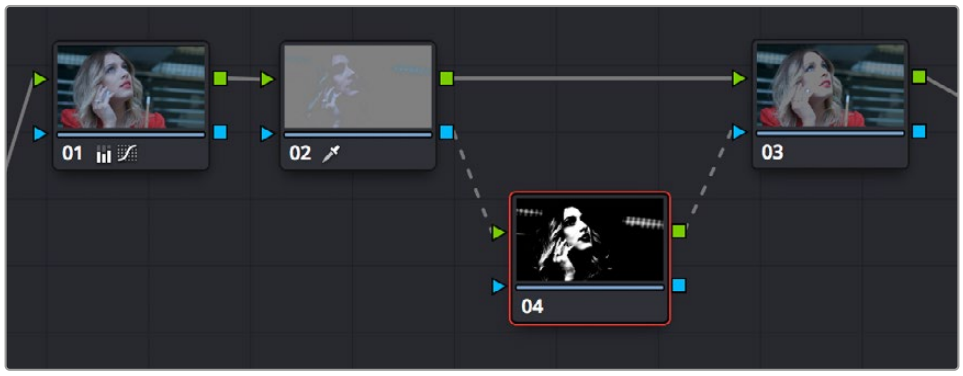
6 Now, you can make your adjustment to Node 6's grade, to lower the contrast, brighten, and increase the saturation of the actor's skin tone.As a result of this operation, the background remains desaturated and contrasty, while the actor's skin tone has the brighter quality we need for the shot.

(Left) An entire clip with a high-contrast grade, (Right) The skin tone graded differently from the high-contrast grade using a key

This example could have been handled in a variety of different ways, but the point is that you can add nodes that connect to the state of the image at any part of a node tree, and use them to generate keys to feed to any other node, regardless of what's happening to the picture in between.

Connecting Key Outputs to RGB Inputs, and Vice Versa

There's another way you can manipulate a key from one node using another in the Node Editor, and that's to connect the key output from one node to the RGB input of another node. When you do this, you can use any of the controls of the second node to manipulate the key, and you can then use the result by connecting the RGB output of the second node to the key input of a third node.



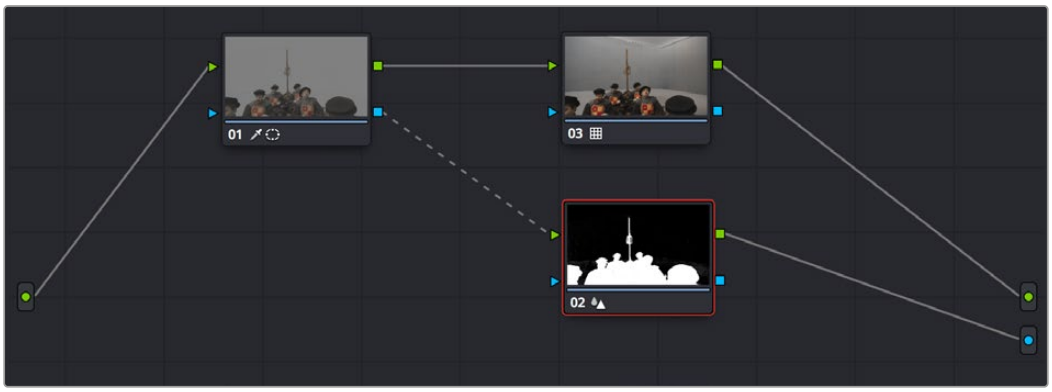
Connecting a key output to an RGB input to adjust a key with a second node's controls

In the node tree shown above, Node 2 pulls a key, Node 4 manipulates the key, and Node 3 uses the key to make a color adjustment.

Keep in mind that a key is just a grayscale image. Setting up this kind of node structure lets you use any of the second node's controls, such as the Custom Curves, Noise Reduction or Motion Blur controls, Sharpen, Midtone Contrast, Lift/Gamma/Gain, Contrast, or Log controls, to manipulate the key in ways you couldn't do using only the Matte Finesse controls.

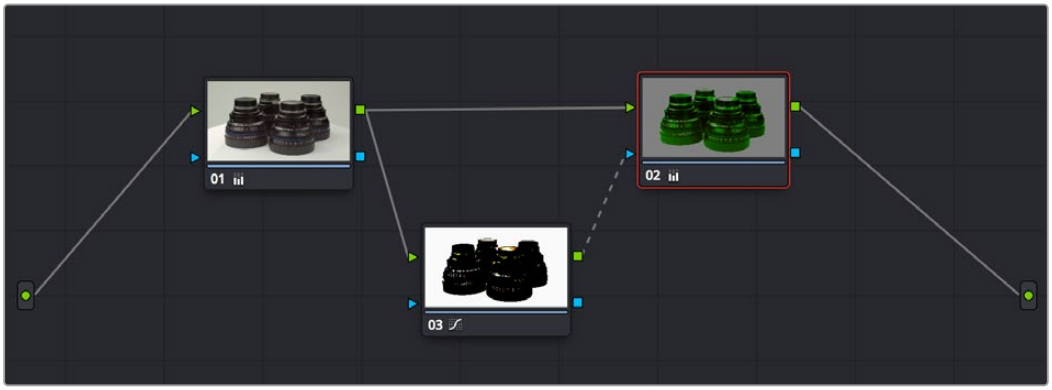
While this technique may not be necessary for conventional color isolations, it can come in very handy when making tricky isolations with hard to key subjects, or when using one of the Qualifier modes

to pull a key to create transparency for compositing using the Node Editor's Alpha output. In this instance, you can connect the RGB output of a node used for key manipulation directly to the Alpha output. In the example, Node 1 pulls a key, and the RGB is connected to Node 3 which is used to color correct the foreground image. The key from Node 1 is connected to the RGB of Node 2, which manipulates the key to clean it up prior to connecting it to the Alpha output block at the bottom right of the Node Editor.



Connecting a key output to an RGB input to adjust a key used to create transparency via the Alpha output

Furthermore, this capability also lets you create keys in other ways besides using the Qualifier palette controls. In the following example, the Contrast and Custom Curve controls in Node 3 create a high-contrast matte of the windows which is blurred. The RGB output of Node 3 is then connected to the KEY input of Node 2, where the resulting key can be used for a variety of adjustments; in this case, to tint the product within the image green. Alternately, this technique could be also be used to create transparency via the Alpha output.



Using a high-contrast color correction as a key

You can manually connect RGB inputs and outputs to Key inputs and outputs by dragging links between them. Alternatively, you can drag and hover a node over an RGB or Key link to insert it. Interconnecting key and RGB inputs and outputs is a powerful capability that lets you create many kinds of workarounds for uncommon situations.

Using External Mattes

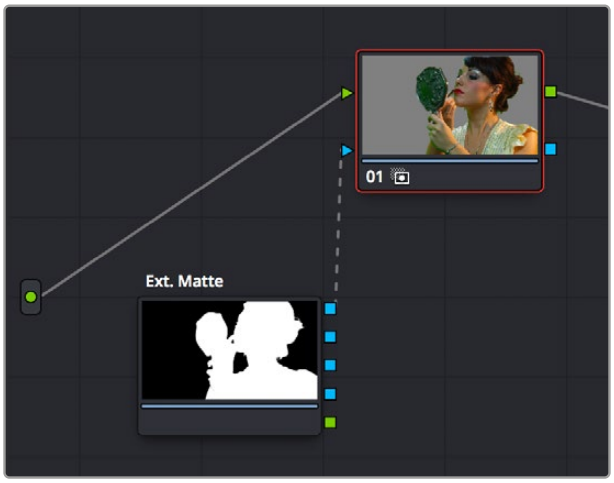
The External Matte node has evolved over the years. What was once purely a means for importing matte channels for defining opacity and limiting adjustments has expanded to become a way to import the RGB channels of a media file to be used for overlaying grain, texture, and stylized distress onto an image, and even as a way to use the channels of a clip itself as a matte.

Matte clips can be added to your project in one of two ways:

- You can add mattes using the Media page, either by attaching them to a clip so a particular matte is only available to a particular clip as part of a Clip grade, or you can add timeline mattes that stand alone in the Media Pool, which are then available to any Track grade.
- You can also add a matte to a clip using the Media Pool in the Color page, by dragging a clip from the Media Pool to the Node Editor. When you do so, that clip is turned into an external matte in the current grade, which you can use as a matte for secondary adjustments, or as a compositing layer (in conjunction with the Layer mixer) for mixing textures or images with your grade. That clip is also automatically attached to the Media Pool clip that corresponds to the clip you're grading, as a clip matte, to help you keep track of which clips are using other clips as mattes.

For more information about adding matte clips in the Media page, refer to "Adding and Removing External Mattes" *see Chapter 18, "Adding and Organizing Media with the Media Pool.""*

Whether attached or unattached, mattes operate within a grade using EXT MATTE (external matte) nodes. EXT MATTE nodes have the following outputs:



An external matte connected to the first node of a grade

- **EXT MATTE Outputs:** Four blue square key outputs let you output the channels contained within the EXT MATTE node, but which channels are available affects what is output. If the EXT MATTE node's source clip has RGBA channels, then these are available as Alpha, Red, Green, and Blue key outputs that you can attach to any other node's key input. On the other hand, if the EXT MATTE node's source clip only has RGB channels, then the key outputs that are made available are Y (luma), Red, Green, and Blue, and a "Use Lum for Alpha Output" setting in the Node Editor contextual menu lets you use the Y channel as a matte.

  An interesting aspect of these four outputs is that each one is dedicated to individual A, R, G, and B color channels. Ordinarily, External Matte clips are written with matte data written simultaneously

to all three RGB channels. However, you could also render separate pure primary-colored mattes to each color channel (a so-called “disco” matte), so that the Red channel has one matte, the Green channel another, and the Blue channels still another, thereby exporting three separate mattes within a single media file, for convenience. If you add another matte to the Alpha channel, you can even export four mattes within a single file. You can then use each one of these mattes individually by connecting the correct output of the EXT MATTE node. (Note: For backward compatibility, projects from versions of DaVinci Resolve previous to 12.5 continue to output RGBY from the square outputs, not YRGB.)

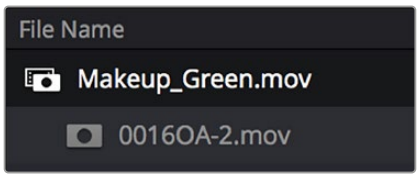
- **RGB Output:** A square green RGB output lets you connect the RGB image data of a matte clip to any other clip’s RGB input. This is especially useful when you’re combining a matte clip with the current clip using a Layer Mixer node, to create a textured composite of some kind.

External Mattes to Limit Adjustments

Going back to the External Matte node’s original use, mattes are typically grayscale media files that represent image opacity, and are meant to be used either as alpha channels for creating opacity within a corresponding RGB clip, or as a matte for limiting effects.

An example of a matte channel would be the key created by a green screen keyer. If you output just the key, that would be an external matte. If you receive an external matte along with an effects clip, you can attach the matte to its corresponding RGB clip in the Media page. Then, you can access that matte via an External Matte node in the Node Editor, so you can use the key it outputs to limit different kinds of corrections you want to apply.

In the following example, the keyed matte of a green screen composite clip is used to apply different corrections to the inside and outside of a keyed composite, in order to make the subject match the background more convincingly.



A matte attached to clip Makeup_Green.mov, as seen in the Media Pool

To use a clip matte to limit an adjustment within a Clip grade:

1. Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.

   By default, the EXT MATTE node that appears has its first output connected to the Connect one of the EXT MATTE node’s triangular key outputs to the key input of a node you want it to limit.

2. Select the node to which the EXT MATTE node is attached, and add an Outside node to make it possible to add adjustments on either side of the matte.

Node Editor displaying the influence of the external matte on multiple nodes when the keys are linked

3 If necessary, select Node 1, and use the Key palette controls to modify the incoming key, inverting or blurring it as necessary to create the isolation you need.

> **NOTE:** Don't select the EXT MATTE node, because it exposes different controls in the Key palette for transforming, flipping, looping, and freezing the matte.

At this point, you can add adjustments to the inside and the outside of this composited shot to improve the composite.

(Before/After) An external matte is used to apply separate grades to the foreground and background of a previously composited clip

Ideally, external mattes are exported so that they match the size and duration of the RGB clip they're supposed to accompany. If they don't match or if you're using some other grayscale clip as an external matte to create some sort of effect, then there are parameters in the Key palette that you can use to retime or transform a matte so it works better in your grade.

To slip the sync of a matte relative to the clip it's attached to:

1 Select the Ext Matte node you want to slip.

2 Open the Key palette, and turn off the Lock Matte checkbox.

3 Raise or lower the Offset parameter until the matte is perfectly aligned with the clip it's supposed to match.

To transform a matte:

1. Select the Ext Matte you want to transform.
2. Open the Key palette, and turn off the Lock Matte checkbox.
3. Use the Pan, Tilt, Zoom, Rotate, Width, Height, HFlip, or VFlip parameters to adjust the matte so it has the correct geometry.

It's worth mentioning that you can attach as many external mattes to a single clip in DaVinci Resolve as you like. For example, if a CGI shot has been delivered with a set of isolation mattes for each of three characters in the scene, you can import all three mattes and use them to isolate adjustments that you want to make in the Node Editor.

Extracting External Mattes from OpenEXR Layers

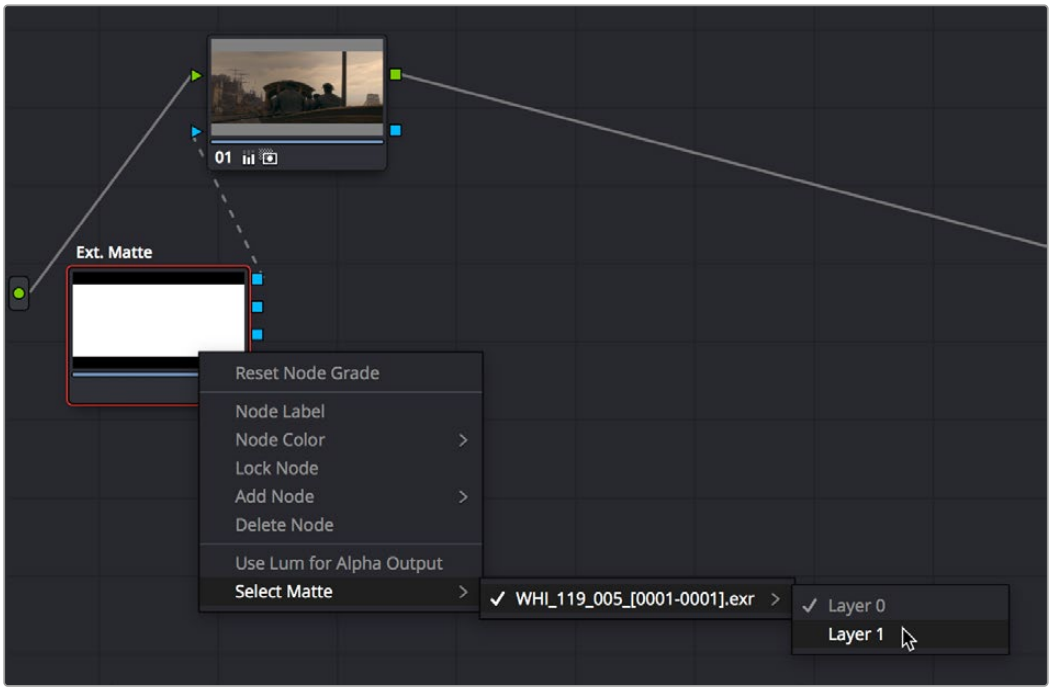
OpenEXR media is capable of containing multiple layers and multiple alpha channels, which can also be accessed from EXT MATTE nodes. As a result, DaVinci Resolve uses a slightly different but related procedure for accessing these mattes.

To extract OpenEXR layers as external matte nodes:

1. Right-click any node, and choose the .exr clip name from the Add Matte submenu of the contextual menu.

   By default, the EXT MATTE node that appears has its first output connected to the Connect one of the EXT MATTE node's triangular key outputs to the key input of a node you want it to limit.

2. Double-click the EXT MATTE node to select it, then right-click it and choose which layer you want to use from the Select Matte submenu.



Right-clicking an OpenEXR file's EXT MATTE node to choose which layer to use

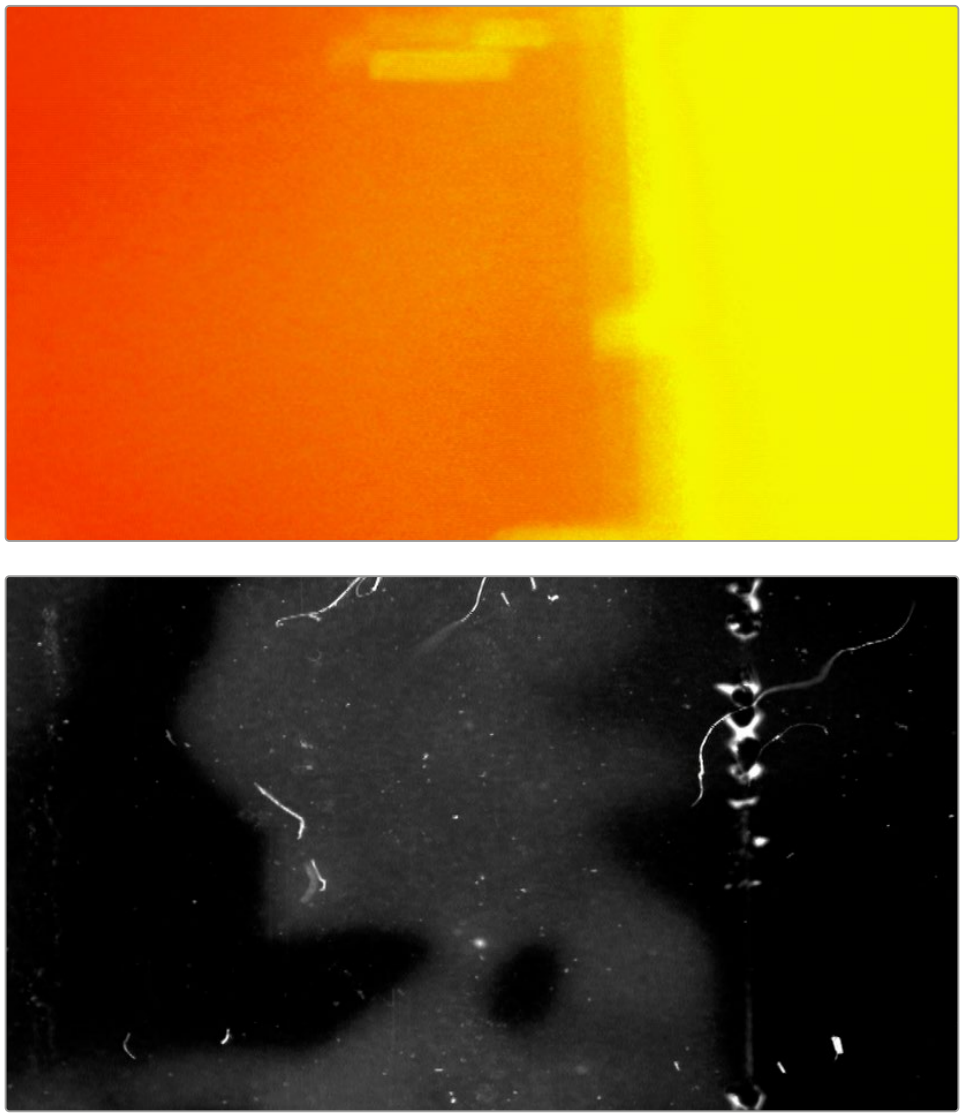
OpenEXR files with multiple RGBA layers (or passes) embedded within them (RGBA + RGBA + RGBA and so on) or OpenEXR files with multiple alpha channels (RGBA + A + A) expose multiple entries in this submenu. Whichever one you choose is the layer that will be used as a matte by that EXT MATTE node.

Once you've extracted an OpenEXR layer, you can use it as you would any other EXT MATTE node described in this section, to limit adjustments (as seen above), or to add texture or transparency (as seen in the following sections).

When working with a node with multiple matte layers, such as an .exr file, you preview individual matte layers. To do so, right-click on the node, select Add Matte from the contextual menu, and hover over the name of the file. A list of all the layers in the node will appear, and by holding down the Option key while hovering over each layer, it will appear in the Viewer. This can let you quickly check to see if you are working with the correct matte layer (arm, wheel, shirt, etc.), regardless of what the matte has been named in the file.

Using External Mattes to Add Texture

You can also use external mattes as creative tools, to add grain and texture. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

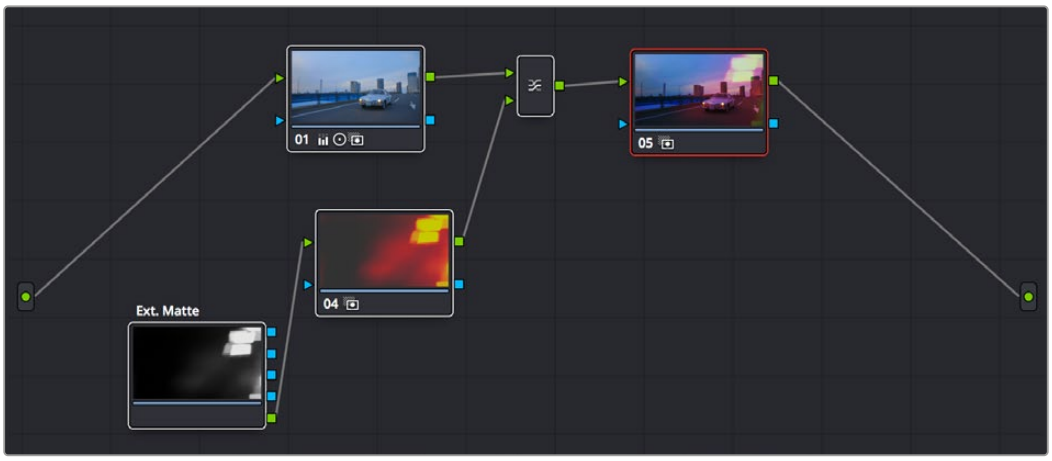


Light leak and dirt and dust images From Warren Eagles' Scratch FX collection (FXPHD), designed to add texture to your grades

Once attached to a clip, external mattes can be exposed in the Node Editor, and their key output can be used just like any other key in a node tree.

To use a clip matte to create texture for a Clip or Timeline grade:

1. When applying a matte as part of a Clip or Timeline grade, right-click any node and choose the attached or timeline matte you want to use from the Add Matte submenu of the contextual menu. Unattached mattes appear in the Add Matte > Timeline Mattes submenu.
2. Disconnect the EXT MATTE node's key output connection to the Key input of the node it's connected to by default.
3. Add a Layer Mixer to the end of the node tree.
4. Disconnect the bottom Corrector node's RGB input, and then connect it to the EXT MATTE node's square RGB output.



A node tree set up to feed an EXT MATTE node's RGB output to the input of a node connected to a Layer Mixer, in order to blend it with the grade using composite modes

5. Right-click the Layer Mixer node, and choose Overlay from the Composite Mode submenu to blend the Ext Matte node most effectively with the grade.
6. If necessary, you can use the grading controls of the Corrector node to which you've attached the EXT MATTE node to change the characteristics of the texture clip, desaturating it for instance. You can also select the EXT MATTE node itself, open the Key palette, and use the Transform, Offset, Loop, or Freeze controls described later to change how the matte appears.

The resulting texture effect, blended with the grade using the Overlay composite mode

TIP: If you want the texture you create to be unaffected by blur or sharpening operations within the grade, be sure to add it to the very end of the node tree.

Using External Mattes to Create Transparency

You can also use an EXT MATTE node to create transparency in a clip, for compositing with clips underneath it on the Timeline.

To use a clip matte to create transparency in a clip:

1. Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.

   Adding an EXT MATTE node to a Clip grade applies the effect to only that clip, whereas adding an EXT MATTE node to a Track grade applies the effect to the entire Timeline.

2. Right-click any empty area of the Node Editor, and choose Add Alpha Output to reveal the Node Tree output on the right that lets you assign a key to be used to define clip transparency.
3. Connect one of the EXT MATTE node's triangular key outputs to the Alpha output at the right of the Node Editor.

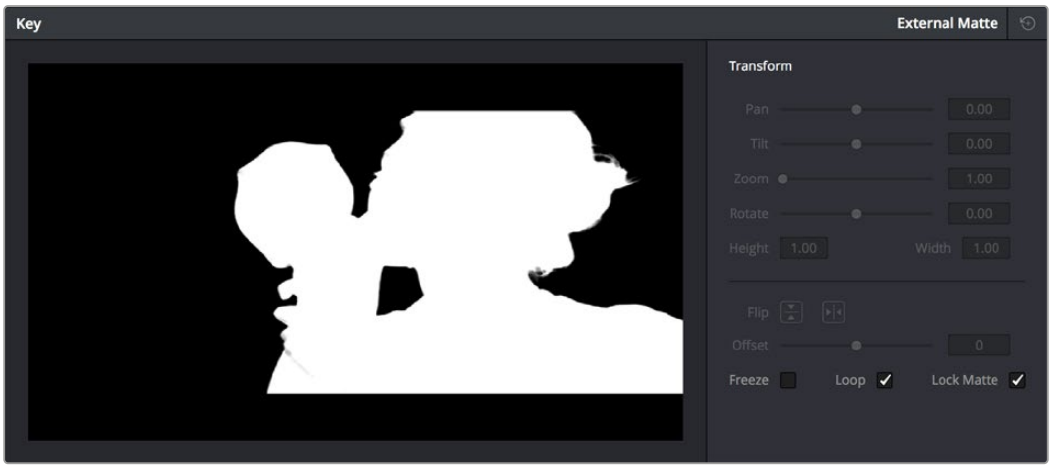
The node setup for using an external matte to composite two layer

The areas of the matte defined by the key are now rendered transparent.

The final composite created using the external matte node

Key Palette Controls for the External Matte Node

When you select an EXT MATTE node, the Key palette displays different parameters only for mattes. Be aware that you must turn off the Lock Matte checkbox before you can make adjustments to transform the matte.



The Key Palette showing a texture layer added as an EXT MATTE node

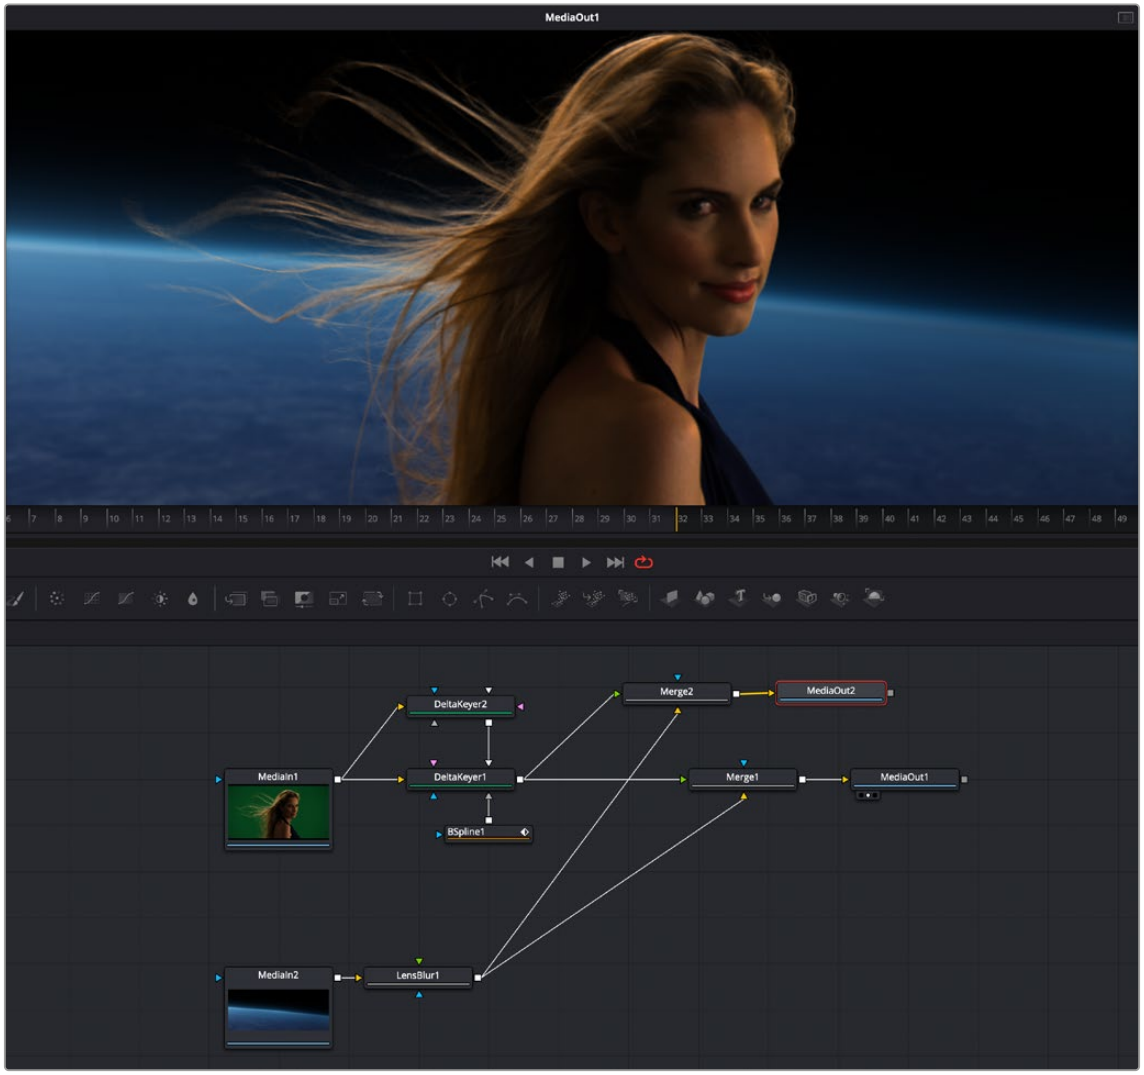
- **Transform:** Standard Pan, Tilt, Zoom, Rotate, Width, and Height parameters let you transform a matte to fit the image better.
- **Flip Image:** Two buttons let you flip the matte clip horizontally or vertically.
- **Offset:** Adjust this parameter to offset the start point of a matte clip.
- **Freeze:** Turning on this checkbox freezes the matte clip on a single frame. Adjust the Offset parameter to choose which frame to freeze on.
- **Loop:** Turning on this checkbox enables matte clips to loop endlessly, which lets shorter matte clips cover longer durations.
- **Lock Matte:** When turned on, locks the sizing of a matte to whatever changes are made to the Input Sizing of that clip, so the matte transforms to follow the clip.

You can also use external mattes as creative tools. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

Using Mattes From the Fusion Page

If you're grading a composite that's been created in the Fusion page, you can feed mattes created in different parts of a Fusion composition to the Color page to use in the grade as well. For example, if you're grading a composite of a foreground actor who's green screen keyed against a background layer, you might want to use the matte generated for the key to protect the foreground subject from an operation in your grade that you only want to affect the background. Happily, this is easy to set up.

In the following Fusion composition, two DeltaKeyer nodes (one to create an overall matte, and one to create a solid matte protecting the core) and one BSpline node (to create a garbage matte) work together to create a finely-tuned matte. This matte is used by the Merge1 node to preserve the subject's hair and composite them in front of a gently blurred (using the LensBlur node) planet, with the final result connected to the MediaOut1 node, which feeds this image to the Edit page and Color page for continued adjustment.

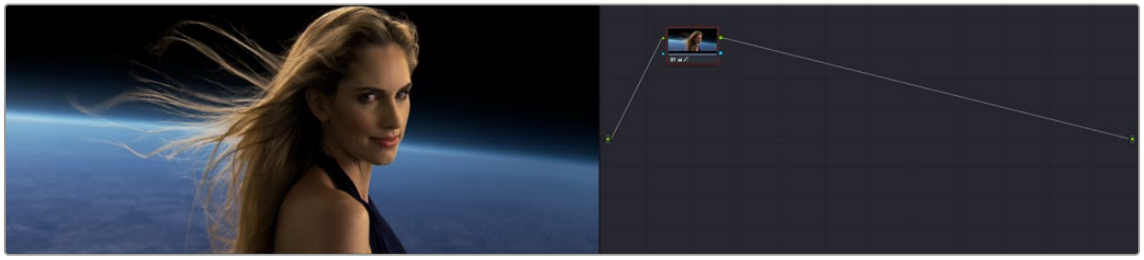


A green screen composition in the Fusion page, outputting the RGB in MediaOut1, and the foreground matte in MediaOut2

Because the Merge1 node outputs the entire composition as a single image, a second MediaOut node (highlighted) is added to output the matte, just in case the colorist might want to use it later.

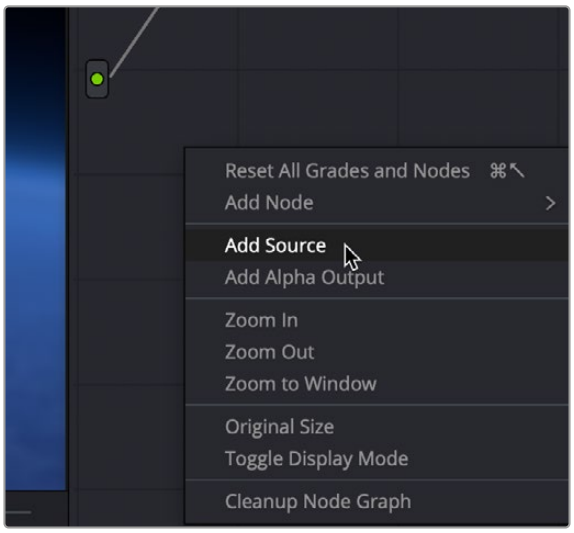
TIP: In this composition, the foreground and background images are different sizes, so outputting the alpha channel of the DeltaKeyer1 node would result in a matte sized to match the foreground image, but that doesn't fit the composition, which is cropping the top and bottom of the foreground image based on the frame size of the widescreen background image. To get around this, the foreground and background images are composited a second time using the Merge2 node, which has the Operator parameter set to "In" to output just the foreground image and matte, as resized by the Merge operation. The resulting MediaOut2 node thus outputs a foreground matte that's properly sized to fit the composition.

On the Color page, the grade in node 1 is applied to the overall final result, which is a single image. After grading, it's decided that the woman appears a bit warm relative to the cool blue of the planet behind.



The composition as it appears in the Color page Node Viewer

Right-clicking the background of the Node Editor and choosing Add Source adds a second source at the left of the Node Editor.

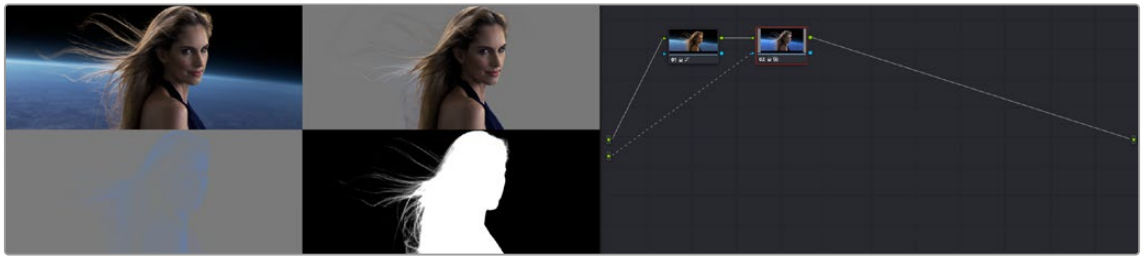


Adding a source to bring in the MediaOut2 node's matte output from the Fusion page composition

This second source corresponds to the second MediaOut node you added to the Fusion page composition, which outputs the Matte as a key in the Color page, usable just like any other key. If you hover your pointer over each source, a tooltip appears letting you know which output corresponds to which node.

Hovering the pointer over a source identifies it in a tooltip

Generally, sources are arranged from top to bottom from the first MediaOut node appearing in a Fusion composition to the last. At this point, you can connect the second Source to the Key input of a second corrector node, using that key to selectively grade just the woman in the foreground (grade exaggerated for effect), without affecting the background. The Viewer is shown with Splitscreen set to Highlight Modes, so you can see the result as well as the key from the Fusion page that's being used by Node 2.



Connecting the second source to a second Corrector node's KEY input to use the matte to limit a correction made to the foreground character

Using the Key Mixer

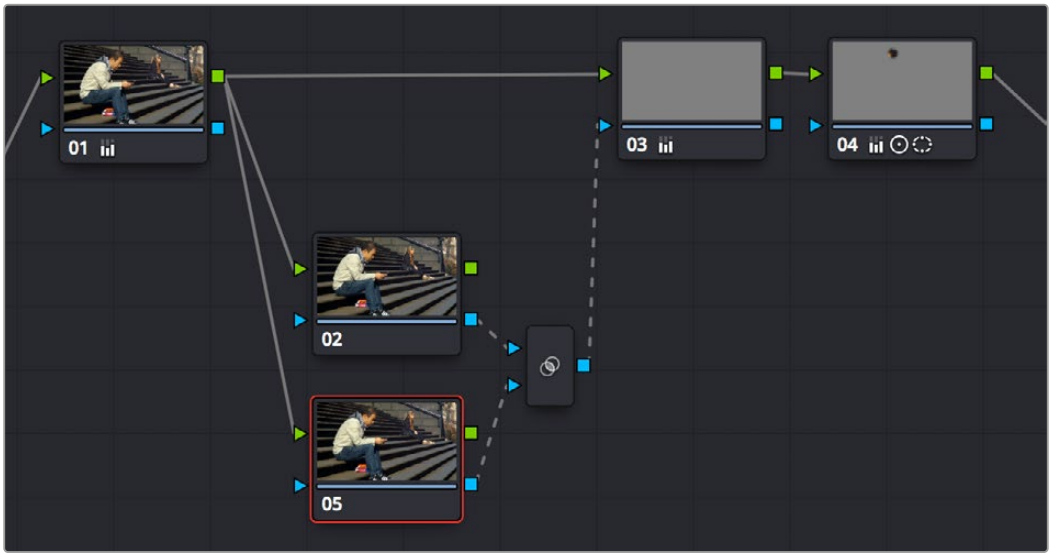
The Key Mixer node lets you mix keys output from multiple Corrector nodes, combining them in different ways to create a single key output. This makes it possible to build much more intricate keys than you can with a single qualifier or set of four windows. In particular, the Key Mixer node is the only way to combine multiple keys made using qualifiers and windows, adding, subtracting, or intersecting them to create a highly specific result.

Adding Two Keys Together

In the following example, you'll learn how to set up a Key Mixer to combine the keys output by two Corrector nodes in a node tree. Then you'll learn how to change the way the input keys are combined using the Key palette.

To combine two or more keys using the Key Mixer:

1. Right-click anywhere on the gray area of the Node Editor, and choose Add Node > Key Mixer.
2. Create two Corrector nodes, then attach their RGB inputs to the RGB output from an appropriate node in the main part of the tree, and attach their key outputs to the key inputs of the Key Mixer.
3. Next, attach the key output of the Key Mixer node to the key input of the node you want to use to make the correction. Remember, the objective is to use the key that's output by the Key Mixer to limit the adjustment being made using another node, in this case Node 3.

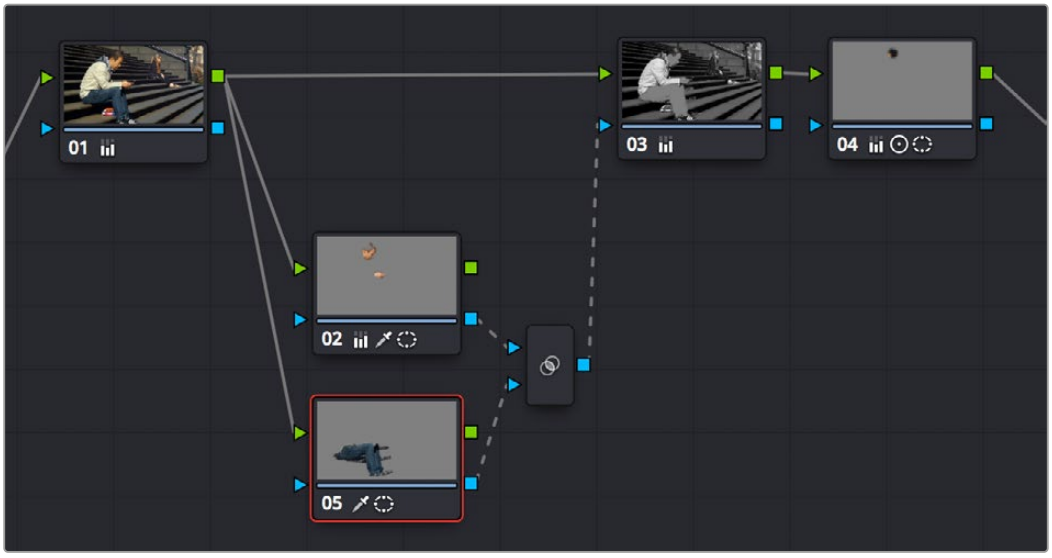


Setting up the node tree you'll need to combine two keys together

Keep in mind, especially since this is a significant reordering of nodes in the Node Editor, that every node needs to be connected properly for the overall grade to work.

4 Now that the node structure is fully connected, use windows, qualifiers, or both to create keys in each of the nodes that you connected to the Key Mixer. In this example, Node 2 is isolating the main skin tone, and Node 5 is isolating the blue of his jeans and hood.

By default, all keys connected to the Key Mixer are added together, as you can see in the Key Mixer's thumbnail.



Combining multiple keys with the Key Mixer

If you wanted, you can use the controls in the Key palette to change this, in order to isolate the intersection of two keys, or to subtract one key from another. This is covered in the next section.

5 Continuing with the previous setup where both keys are added together by default, selecting Node 3 and dropping the saturation to be very faint stylizes the entire background, while leaving the various hues of the man we've isolated alone.

Final grade, the talent in color with a B&W background

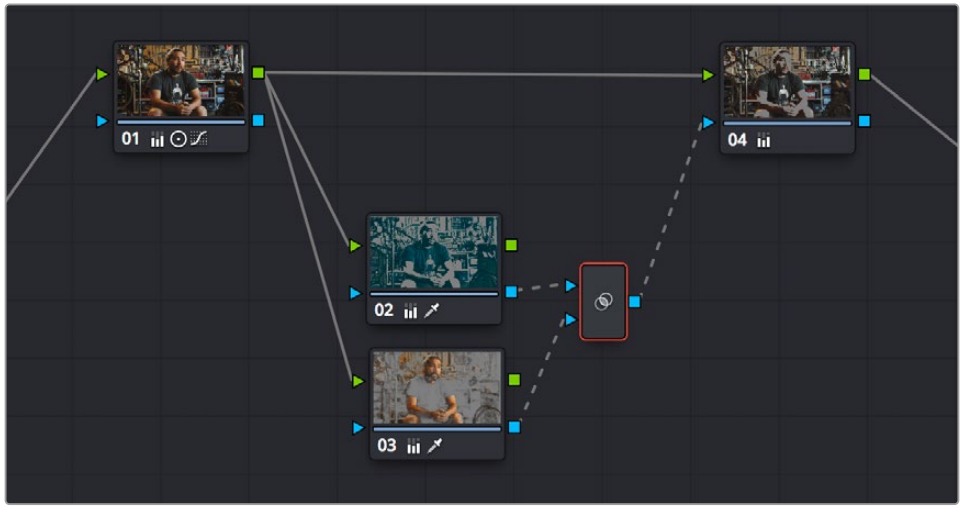
Subtracting One Key from Another

The way multiple keys are combined within the Key Mixer depends on a pair of Key Input buttons you can toggle using the Key palette. In the following example, a partial green tint is washed throughout the midtones of the image using a qualifier, but you want to exclude the man's skin tone from this operation. Using the Key Mixer, you can subtract one key from another to accomplish this with ease.

A selective blue tint added to the midtones of the image includes the red sign.

To change the Key Input settings for a node connected to a Key Mixer:

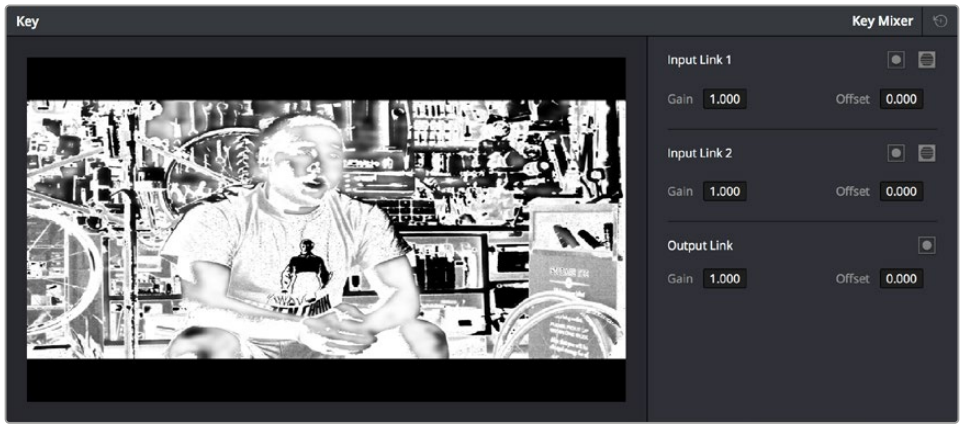
1 In this example, Node 2 is isolating part of the midtones of the image, and feeding its key through the Key Mixer to Node 4, which is using it to apply a partial blue tint. However, in preparation for subtracting the skin tone from this operation, Node 3 is isolating the man's skin tone.



A node setup in preparation of subtracting the Bar sign from the midtone isolation being used to add a partial blue tint

2 To reveal the controls you'll use to change how the key from Node 3 interacts with the key from Node 2, double-click the Key Mixer node to select it.

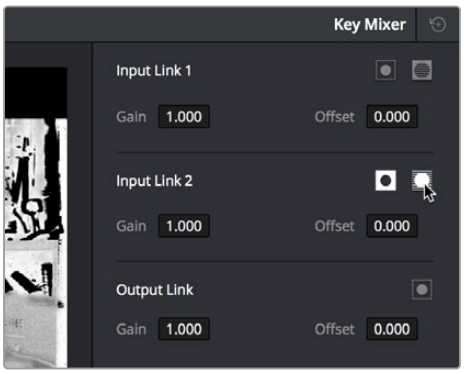
3 Open the Key palette; a list of all input links that are connected to the Key Mixer appears at the right.



The input list of the Key Mixer node

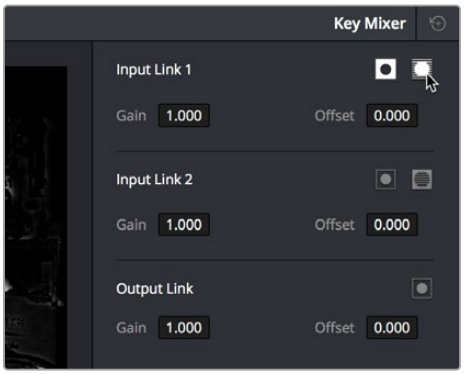
4 Within each list entry is the input name (Input Link 1, Input Link 2, etc.), a Matte control, a Mask control, a gain parameter, and an offset parameter.

To subtract Node 3's key from that of Node 2: Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 2.



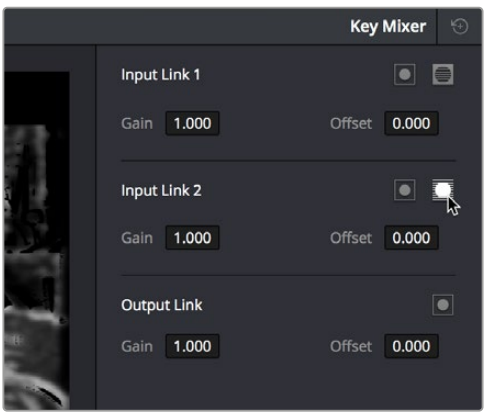
Turning on Matte and Invert for Input Link 2 to Output Node 3 subtracted from Node 2

To subtract Node 2's key from that of Node 3: Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 1.



Turning on Matte and Invert for Input Link 1 to Output Node 2 subtracted from Node 3

To limit the output to the intersection of both keys: Turn on the Key Input Matte button for either Input Link 1 or Input Link 2.



Turning on Matte for Input Link 1 to output the intersection of two mattes

To invert the resulting matte you've created: Turn on the Output Link Invert button.

When you're finished, if you choose to subtract Node 3's key from that of Node 2, the result should resemble the following screenshot.

The result of subtracting a key of the man's face from a key of the overall midtones of the image, and using that to add a selective green tint

Adding Inputs to Key Mixer Nodes

New Key Mixer nodes have two key inputs by default. If necessary, additional inputs can be added in order to combine even more keys with one another.

To add inputs to the Key Mixer:

- Drag the Key Output from a corrector node to the Key Mixer.
- Right-click a Key Mixer node, and choose Add One Input.

When combining three or more keys, the interaction of keys using the Key palette controls becomes even more complex, but the rules outlined above still apply.

Using the Key Palette

For example, the Key Input Invert control is always enabled when you add an Outside node, which is why the Outside node applies adjustments to the inverse area of the previous node. If you turn this control off, that node's key will exactly mirror the original key being fed to it from the previous node.

The controls that are available in the Key palette vary depending on what kind of node you have selected:

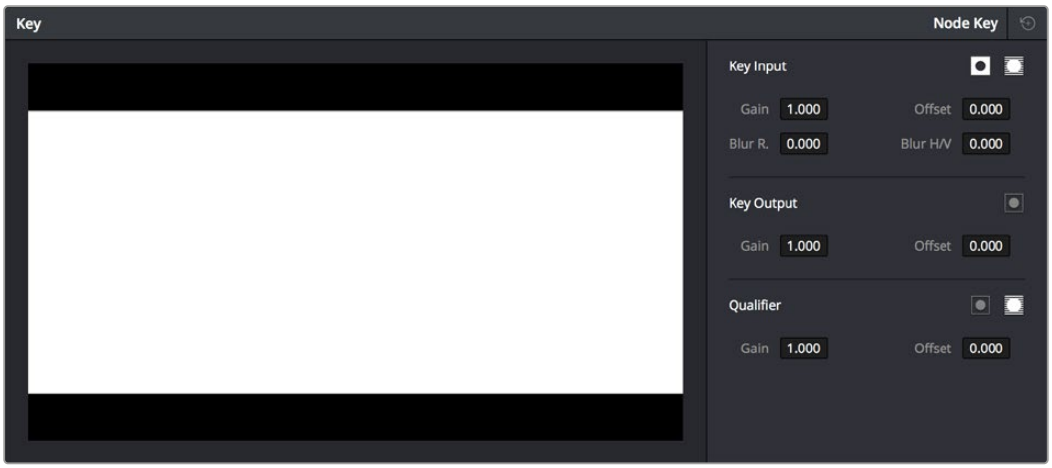
- **Corrector Nodes:** Have three sets of parameters. Key Input parameters let you make adjustments to keys being fed through a node's Key Input connection. The Key Output parameters let you make adjustments to the key data being output by a node's Key Output connection, and includes the incredibly powerful Offset Gain parameter that governs the strength of that node's contribution to the overall grade. Finally, the Qualifier parameters let you make adjustments to the internal key created with the HSL Qualifier or Window controls. This functionality is covered more extensively in the next section.
- **Ext Mattes:** Have two sets of parameters. Transform parameters let you make geometric transformations to a matte so it fits the clip it's being applied to better. An Offset control lets you slip the sync between an external matte and the clip to which it's applied. This functionality is covered in the section on external mattes.
- **Key Mixer Nodes:** Have two sets of parameters that are dependent on which of the connections attached to a Key Mixer's key inputs is selected. Input parameters let you adjust how much of a contribution a key makes to the total key mix, and whether the contribution is additive or subtractive.

The Output parameters let you adjust the inversion and strength of the key that's output by the Key Mixer. This functionality is described more extensively in the Key Mixer section.

Layer Mixer and Parallel Mixer nodes have no adjustable controls in the Key palette.

Using the Key Palette to Affect Corrector Nodes

When you open the Key palette for a selected Corrector node, you can adjust the following parameters:



Key palette showing controls when a node is selected

Key Input Controls

- **Input invert:** Inverts the key being fed into the key input. Off by default.
- **Input matte:** Lets you switch the key input between Matte and Mask modes. In Matte mode (on by default) the key input combines via intersection with keys generated internally using the Qualifier or Windows palette. In Mask mode, the key input is added to the internal key instead.
- **Gain:** Controls the strength of the key connected to the key input.
- **Offset:** Controls the contrast of the key connected to the key input.
- **Blur Radius:** Blurs the key connected to the key input
- **Blur H/V Ratio:** Alters the horizontal/vertical ratio of the blur that's being applied to the key input.

Key Output Controls

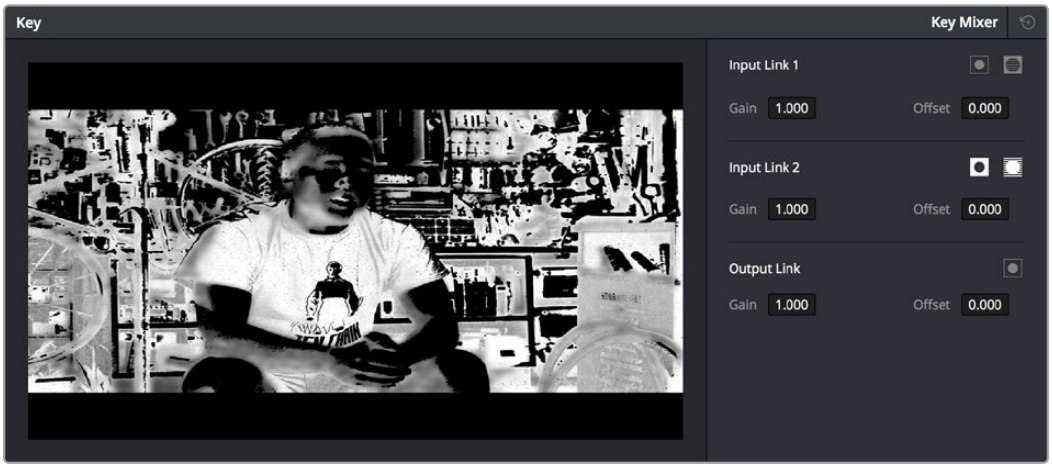
- **Qualifier invert:** Inverts the overall key.
- **Gain:** Using the key output, this parameter governs the strength of that node's contribution to the overall grade. Setting Gain to 0 results in that node having no effect at all, while the default setting of 1.00 applies the full strength of any adjustments made with that node. The maximum setting of 2.00 increases the intensity of any part of the key output that's less than 100 percent white. You can also use this parameter to keyframe the key output to fade that node's contribution in or out with one set of keyframes.
- **Offset:** Lets you adjust the contrast of the Output key. This has no effect if the entire key is 100 percent white (a solid key).

Qualifier Controls

- **Qualifier invert:** Inverts the key created by that node's Qualifier palette.
- **Qualifier matte:** Lets you switch the interaction of the keys generated by the Qualifier and Window palettes between Matte and Mask modes. In Matte mode (the default), the Qualifier and Windows palettes combine via intersection. In Mask mode, they're added together instead.
- **Gain:** Lets you raise or lower the strength of the key generated by the Qualifier palette.
- **Offset:** Lets you adjust the contrast of the key generated by the Qualifier palette.

Using the Key Palette to Adjust Key Mixer Controls

When you open the Key palette for a selected Key Mixer node, you can adjust the following controls:



Key palette showing controls when a Key Mixer is selected

- **Input list:** A list of every input that's connected to the Key Mixer. Each entry on the list has the following controls:

  Input name: The name of each node connection attached to that key mixer, such as Input Link 1, Input Link 2, and so on.

  Input invert: Inverts the key being fed into this particular input. Off by default.

  Input mask: Lets you switch the key input between Matte and Mask modes. In Matte mode (on) the key input combines via intersection with other inputs connected to the Key mixer. In Mask mode (off by default), the key input is added to the other key inputs connected to the Key mixer.

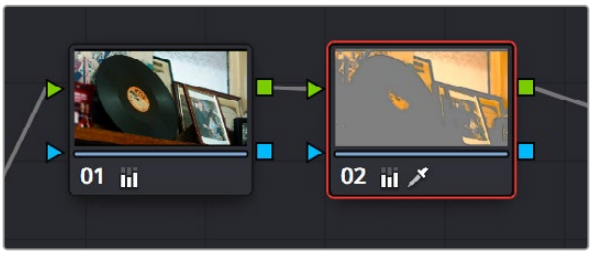
  Gain parameter: Decreases or increases the intensity of that input matte's contribution to the resulting output matte.

  Offset parameter: Adjusts the contrast of that input matte's contribution to the resulting output matte.

- **Output invert:** Inverts the overall result of the various Input Link interactions.
- **Gain:** This parameter increases or reduces the strength of the resulting output key. Setting Gain to 0 results in all inputs being set to black, while the default setting of 1.00 outputs the combined mattes at full strength. The maximum setting of 2.00 increases the intensity of any part of the key output that's less than 100 percent white, which can have the practical effect of "growing" soft edges. You can also use this parameter to keyframe the key output to fade that node's contribution in or out with one set of keyframes.
- **Offset:** Lets you adjust the contrast of the Output key.

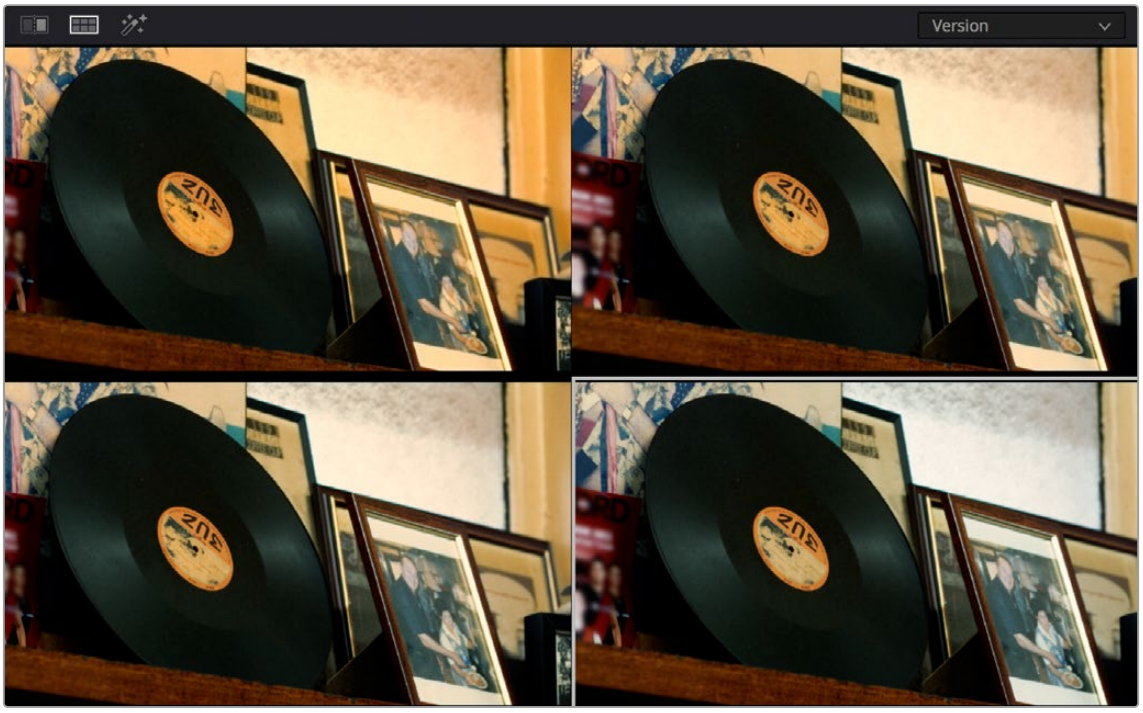
The Many Uses of Key Output Gain

Several of the techniques discussed in here and in “Secondary Qualifiers,” can be further customized using the Key Output Gain parameter, which makes it easy to control the strength of a node’s effect on your grade with a single adjustment. In the following example, two simple Serial nodes are applied to a clip, with the first one expanding image contrast, and the second one using a variety of controls to add some extreme warmth to the highlights.



A tint applied only to the highlights of the image

If you decided that you want to reduce the amount of warmth added by the second node without readjusting the controls you used to create the effect, you could open the Key palette and lower the Key Output Gain parameter to fade the effect with a single adjustment.



Four versions of this grade shown using the Versions option of the Split Screen controls, with Output Gain set to 1, .75, .5, and.25 for comparison

This principle also works for controlling the strength of individual nodes that are being combined in parallel, that are combined using the Layer node, or for simply fading out the effect of any node in the node tree you want to “turn down” a bit.

Chapter 145

Channel Splitting and Image Compositing

This chapter begins by showing node structures you can use to isolate, split apart, convert, and recombine the image channels of clip in different ways. This includes ways of using the additional image channels that are provided in some types of media.

The second part of the chapter shows ways that you can do image compositing right in the Color page, with techniques for using external mattes for compositing, and using qualifier keys to do green- and blue-screen compositing against other layers in the Timeline.

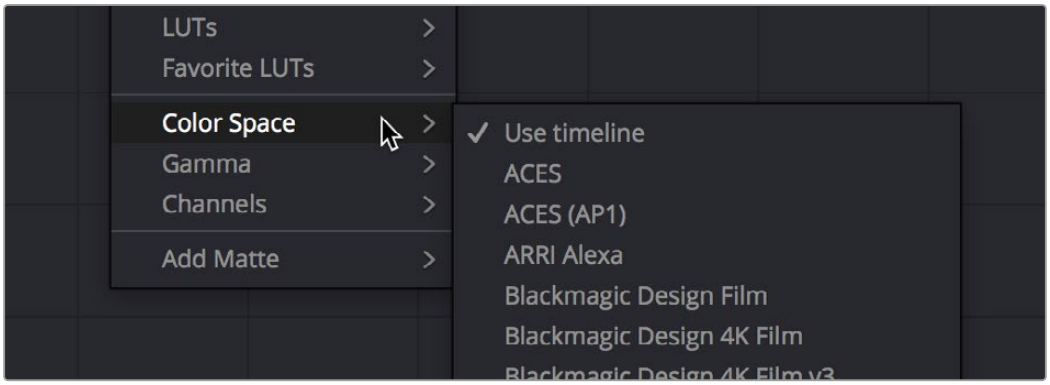
Isolating, Splitting, and Converting Color Channels

DaVinci Resolve provides two different methods of making channel-specific adjustments, depending on whether you need to apply an adjustment to just one channel within a single node, or apply separate adjustments to all three channels across several nodes.

Enabling, Disabling, and Converting Node Channels

Within the contextual menu of each node in the Node Editor is a series of four options:



Expanded choices for choosing a color space and gamma for image processing within a node, and for disabling channels

While the ability to change the color space in which a particular node's operations work from the RGB default has been available for many versions, the list of available color spaces was greatly expanded in DaVinci Resolve 15 (all the previous options such as Lab (CIE), HSL, and YUV are still there). Additionally, you have the option of choosing the gamma that node works with as well, with a similarly long list of options.

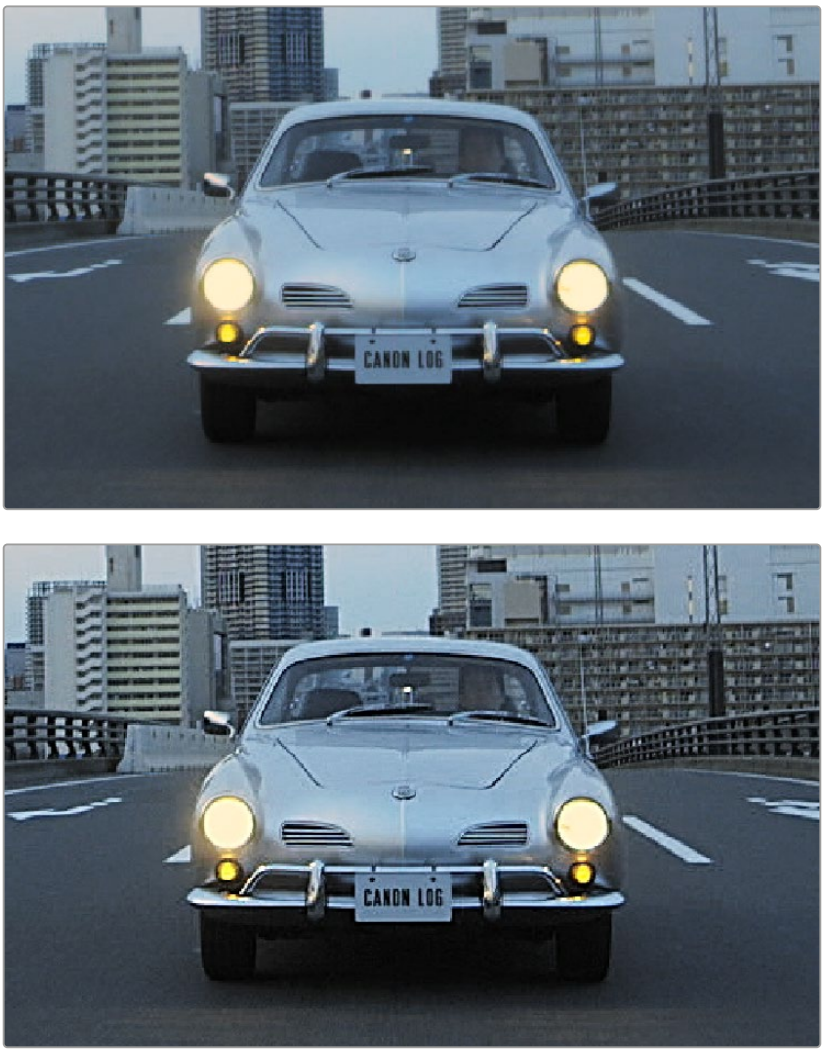
Choosing a node-specific color space and gamma does not directly alter the image, as with the Color Space Transform ResolveFX plugin. Instead, changing a node's color space and gamma alters what type of image channels the red, green, and blue controls affect, and how the adjustments you make within that node are applied. For example, this lets you make a temperature adjustment with a node's gamma set to Linear, which in some instances may be mathematically advantageous.

Additionally, three checked Enable Channel 1–3 options let you turn individual channels off or on, limiting which channel that node's adjustments will actually affect.

In the following example, you'll see how to use these features to selectively sharpen just the Y' (luma) of an image without affecting the chroma, which can be a more subtle effect than simply sharpening the entire image.

To use channel disabling and color space conversion to sharpen luma only:

1. Add a node with which to apply the sharpening you want to the current clip.
2. Right-click the new node, and choose YUV from the Color Space submenu of the contextual menu.
3. Apply sharpening by doing one of the following:
   - Using that node's contextual menu, uncheck Enable Channel 2 and Enable Channel 3, which correspond to the U (Cb) and V (Cr) channels, leaving only Channel 1 (Y) enabled. Then, open the Blur palette, and drag the ganged Radius sliders down to sharpen the Y channel.
   - You can also just open the Blur palette, ungang the Radius sliders, and drag the red slider down to sharpen the Y channel, since any control with three gangable sliders will automatically assign those sliders to whichever channels are used by the currently selected Color Space.



(Before) The original image, (After) Sharpening applied to only the Y' channel of the image

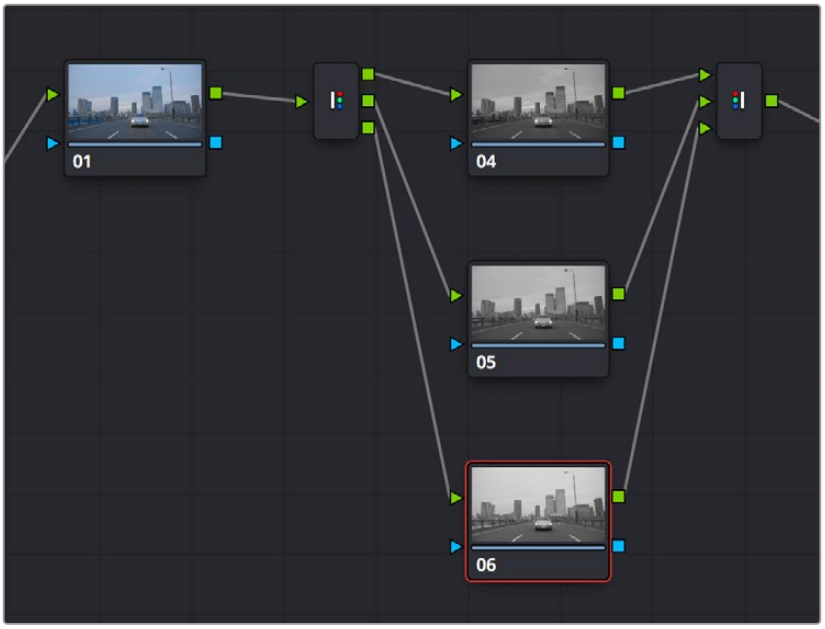
As you can see, while the Blur palette ordinarily provides separate R, G, and B controls that can be unganged from one another, the Color Space submenu lets you apply sharpening to the channel definitions of other colorspaces, providing many other corrective and creative possibilities with the same controls.

Splitting Channels with the Splitter/Combiner Nodes

Another method of applying corrections to individual color channels is using the Splitter/Combiner nodes, which break the Red, Green, and Blue channels apart into separate node tree branches, each capable of accepting multiple serial and parallel nodes of image adjustment. There are two ways you can create a Splitter/Combiner node structure.

Methods of adding Splitter/Combiner nodes:

- **To add a premade Splitter/Combiner node structure:** Choose Color > Nodes > Add Splitter/Combiner Nodes (Option-Y). A Splitter and Combiner node appear already connected to three Corrector nodes, one for each color channel.
- **To manually construct a Splitter/Combiner node structure:** Right-click in any empty area of the Node Editor, and choose from the Add Node submenu to create a Splitter node, a Combiner node, and three Corrector nodes, wiring them together as necessary to create the desired effect.



The Splitter Combiner node structure

The Splitter node takes an incoming image and provides individual outputs for each color channel (top/red, middle/green, bottom/blue). When you connect each of these outputs to a Corrector node, that color channel automatically connects to all three internal channels of that node, so that the default three nodes in a Splitter/Combiner structure are internally processing red/red/red, green/green/green, blue/blue/blue. The Combiner then pulls the Red, Green, and Blue channels out of each node connected to its three inputs, and reassembles them into a single RGB image again. Of course, what happens in between the Splitter and Combiner is entirely up to you.

One of the simplest ways of showing the possibilities of this node structure is to combine it with Node Sizing in the Sizing palette. Using Node Sizing, you can correct for misaligned channels in older archived video, or create channel misalignments for creative looks. In the following example, a simple Node Sizing adjustment to a split Blue channel will create an interesting “prism vignette” effect.

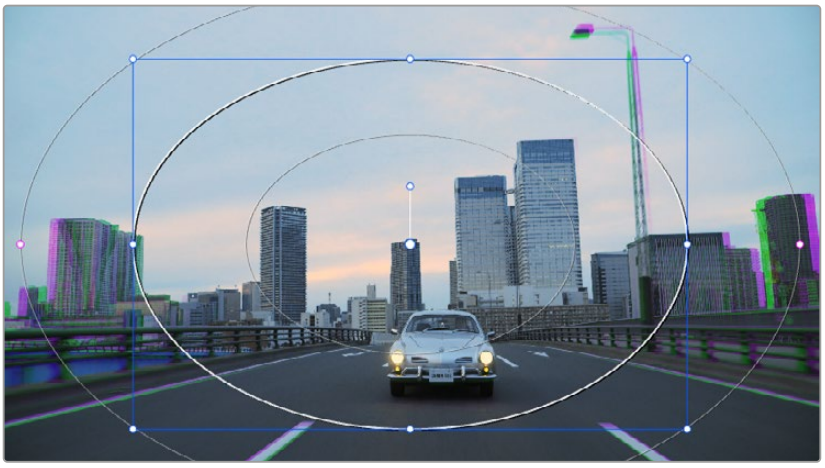
To use Node Sizing on individually split channels:

1. Choose Nodes > Add Splitter/Combiner Node (or press Option-Y) to add a premade Splitter/Combiner node structure to the Node Editor.
2. Select the middle of the three Corrector nodes appearing in between the Splitter and Combiner nodes (Node 5 in the following screenshot).
3. Open the Sizing palette, choose Node Sizing from the Mode drop-down, and then raise the zoom parameter by a small amount; this example uses 1.014.

Zooming just one color channel using the Splitter/Combiner nodes

As you can see in the screenshot, just the Green channel has been zoomed in on across the entire image. This is only possible using Node Sizing. This is cool, but not quite what you need.

4. Open the Window palette, add a Circular window, turn on its Invert control, and transform it to be a very soft, horizontally aligned vignette. This limits the individual scaling done to the Green channel to just the outer edge of the image, similar to a lens with excessive chromatic aberration.



The resulting channel split effect

You could easily keep going, applying varying amounts of zoom with different window shapes to each of the other color channels, and perhaps adding some blur to enhance the effect, but this example should show the creative potential available when using this technique.

Multi-Channel RED HDRx Support

The RED EPIC, SCARLET, DRAGON, and WEAPON cameras are all capable of shooting in an HDR mode that effectively "brackets" two different exposures of each frame. The resulting image data stores two channels of image data: the regular exposure, and a "highlight exposure" that's underexposed by a user-selectable margin (+3, +4, +5, or +6 *f*-stops difference).

By default, the Input bar in the node graph feeds the regular exposure to your grade's node tree. To take advantage of the additional "highlight" exposure, you can add an additional Source input to the node graph that feeds a second stream of image data that you can mix with the regular exposure in different ways.

NOTE: You can also take advantage of the highlight exposure of RED HDRx media by enabling and adjusting the Magic Motion controls in the Camera Raw palette.

To set up a node tree combining the normal and highlight HDR versions:

1. Using the first default node (Node 1), grade the image to see if you even need to use the alternate exposure that's available. We'll assume for this example that you do. In this example, the sky of the default exposure is pretty blown out, but there may be detail that can be retrieved using the highlight exposure.

Using HDRx images with the Layer Mixer

2. Create a Layer Mixer node by choosing Nodes > Add Layer (Option-L).

   Two nodes are created, a Layer Mixer node that's added after Node 1, and a third node (Node 3) that's connected to a second RGB input of the Layer Mixer node in parallel to Node 1.

The Source currently supplies two input, but you can add a second source, which is the short exposure in the HDR image

3 Right-click anywhere within the node graph (except on a node) and choose Add Source from the contextual menu.

A second Source input appears underneath the first, which outputs the highlight exposure of the image as a separate image stream.

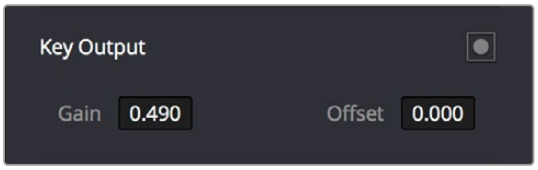
A node tree that uses a Layer Mixer node to mix two Corrector nodes, each connected to separate outputs for the regular and highlight exposures

4 Delete the connection between the top Source input and Node 3, and then connect the bottom Source input to the RGB input of Node 3.

Immediately, the image in the node thumbnail and Viewer updates to show the darker, underexposed version of the HDR image. This is because, by default, the Layer Mixer is mixing 100% of Node 3 over Node 1.

5 Select Node 3 and use one of the following two procedures to create a useful combination of the two exposures:

To create a mix of the two exposures, open the Key tab, and drag the Key Output Gain slider to lower the contribution of Node 3 to the overall image. Using dynamics (keyframing), this is a good way to animate a dissolve from the regular exposure to the highlight exposure if you're going from a dark environment to a bright environment in the same take and you want to create a smooth transition between both exposures.

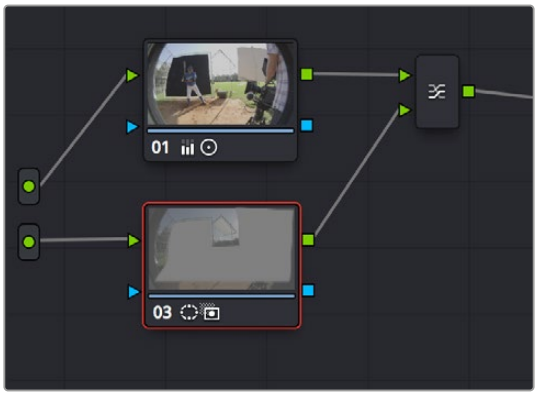


Dissolving between the regular and highlight exposures of RED HDRx media using the Key Output Gain slider of a Corrector node connected to a Layer Mixer node

TIP: You can also use the Blend Type and Blend Bias parameters in the Camera Raw palette to blend the two exposures without building a dedicated node tree.

To use the highlight exposure to selectively put detail back into the image (for example, to retrieve blown-out windows), use a Power Window, HSL Qualification, or a combination of the two to isolate the region you want to retrieve in Node 3. (Be careful if you're using HSL Qualification to combine both exposures, as keyed edges can be tricky to blend.)

Isolating a region of the image to replace using the highlight exposure image of a RED HDRx clip



Final node display with isolations

A Note About RED HDRx Media and Performance

Since RED HDRx media records two complete streams of image data, DaVinci Resolve must simultaneously decode two separate tracks whenever you add a second Source input. (If you don't add the second Source input, only the first stream is decoded.)

Because of this, whether you're relying on your computer's CPU or GPU to decode RED media, you'll get half the performance when using the highlight stream of an HDR clip.

To improve performance, you can enable the Smart Cache by choosing Playback > Render Cache > Smart. This automatically caches all raw source clips to the current codec set in the Render Cache Format parameter of the Master Settings panel of the Project Settings. Alternatively, you can enable the User Cache, and cache all HDRx clips manually by right-clicking them and choosing Render Cache Fusion Output > On. DaVinci Resolve renders all cached clips while you're paused, so the next time you play a cached clip, it will play at full speed.

If you regularly use RED HDRx media, multiple high-end GPU cards are recommended for optimal decoding performance.

Introduction to Compositing Using the Alpha Output

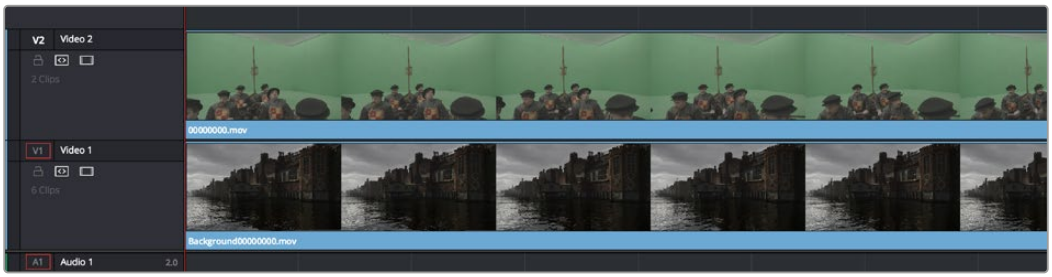
While DaVinci Resolve can use the alpha channel of imported media for compositing, the Alpha Output in the Node Editor is an optional output that you can turn on to create clip transparency using operations inside DaVinci Resolve to create composites against other clips on lower video tracks. There are many ways of using the Alpha Output, but this section will focus on three examples.

Using a Qualifier Key to Create Transparency

In this first example, the Alpha Output will be used to composite a green screen clip with a background plate.

A green screen clip, ready for compositing

In preparation for this composite, the background plate is on track V1 of the Timeline, and the green screen clip has been superimposed on track V2.

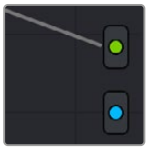


A superimposed green screen clip on track V2 of the Timeline, above a background plate on track V1, ready for compositing

To create a chroma-key composite in the Color page:

1 Right-click anywhere within the gray area of the Node Editor and choose Add Alpha Output to add the Alpha Output at the right of the node graph.

An Alpha Output appears underneath the Node Tree output at the right of the Node Editor.

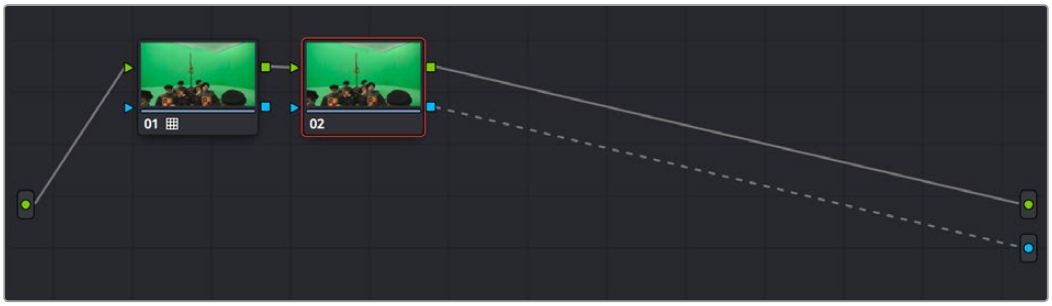


The image Node Tree output with Alpha Output below

2 You'll want to use Node 1 to color correct the image to optimize it for keying. In this example, the foreground plate is log-encoded, so a LUT is added to Node 1 to normalize it.

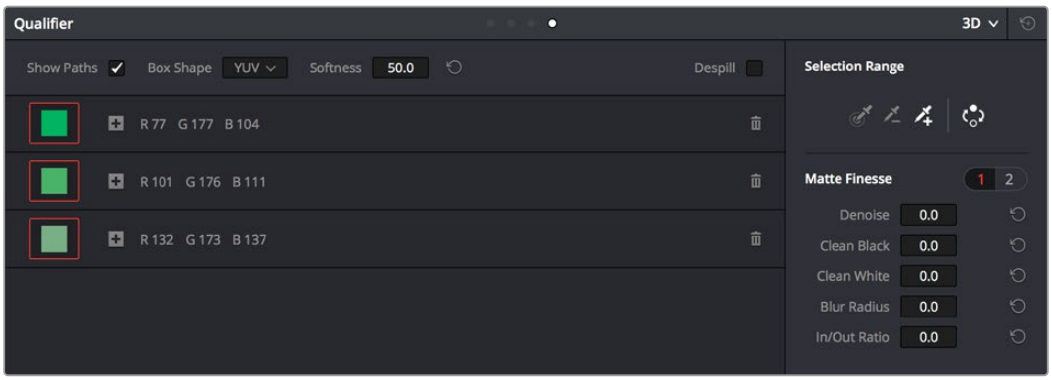
3 Add a Serial node after Node 1 and connect its key output to the Alpha Output. This is a fast way to build this composite if you're confident that the corrections you've made in Node 1 won't adversely affect the key (or if you know they'll improve it by expanding the contrast of a flat-contrast source clip).

Alternately, you could create a second processing branch by adding a disconnected node (Node 2), connecting the Source node to its RGB input, and then connecting its key output to the Alpha Output you just added. Creating a second image processing branch from which to pull your key lets you key directly from the source (assuming the source is fit to key without adjustment), avoiding any problems that grading the first node could introduce to the key.



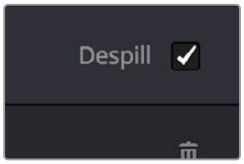
Node 1 grades the clip, expanding contrast to improve both the image, and its ability to be keyed. Node 2 uses Qualifier controls to pull the key.

4 Use the Qualifier controls of Node 2 to key out the green background, and then turn on the Invert checkbox to create the proper composite. In this example, we're using the 3D Qualifier mode to pull a high-quality key.

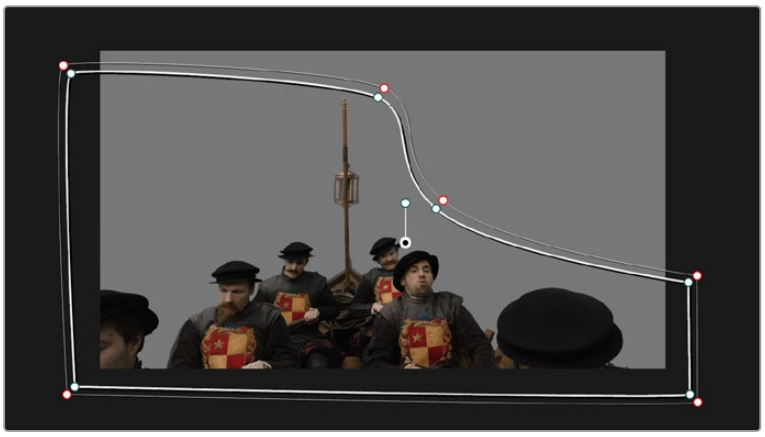


An HSL Qualification to key the green feeding the Alpha Output to create transparency

5 If there's green spill in the composite (or blue in cases where you're keying a bluescreen) you can turn on the Despill checkbox to eliminate it.

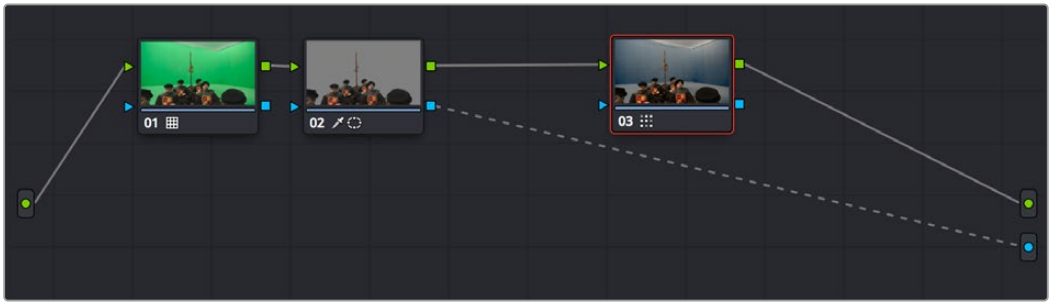


6 You can also use a Power Window to garbage matte out any elements you don't want intruding into the shot, using the Tracker palette if necessary to make the window follow the motion of the foreground subject.



A PowerCurve used to garbage matte out unkeyable lighting fixtures

7 If necessary, you can add another node to the output of Node 2 to make whatever corrections are necessary to the background plate clip to make the composite blend more seamlessly. For example, with this additional node selected, you could right-click the background clip and choose "Shot Match to This Clip" to use the automatic shot matching in DaVinci Resolve to adjust the foreground to match the background.



Adding more color adjustments to a node added after the qualifier

With all this set up, you end up with a nice green screen composite that's visible in both the Color and Edit pages.

The result, with a window garbage matte cropping out the equipment, ready for further refinement

Using a Matte to Create Transparency

If you've been provided with a separate Matte clip for defining clip transparency, you can use that Matte clip within the node tree of a superimposed clip to create a composite using the Alpha Output.

To create a composite using an external matte:

1 To associate an external matte with a clip, open the Media page, select the clip you want to add a matte to in the Media Pool, navigate to the matte file using the Library browser, and then right-click the matte file and choose Add as Matte.

> For more information on importing mattes,
> *see Chapter 144, "Combining Keys and Using Mattes."*

2 Open the Color page and select the foreground clip in the Thumbnail timeline, then right-click Node 1 in the Node Editor and choose the matte you added from the Add Matte submenu.

An EXT MATTE node appears underneath Node 1, with the first of its four key outputs connected to Node 1's key input. (Working with external mattes is covered in more detail in a prior section of this chapter.)

3 Now, right-click anywhere within the node graph (other than on a node) and choose Add Alpha Output from the contextual menu.

An Alpha output appears underneath the Node Tree output.

4 Drag a connection line from the second key output of the EXT MATTE node to the Alpha output.

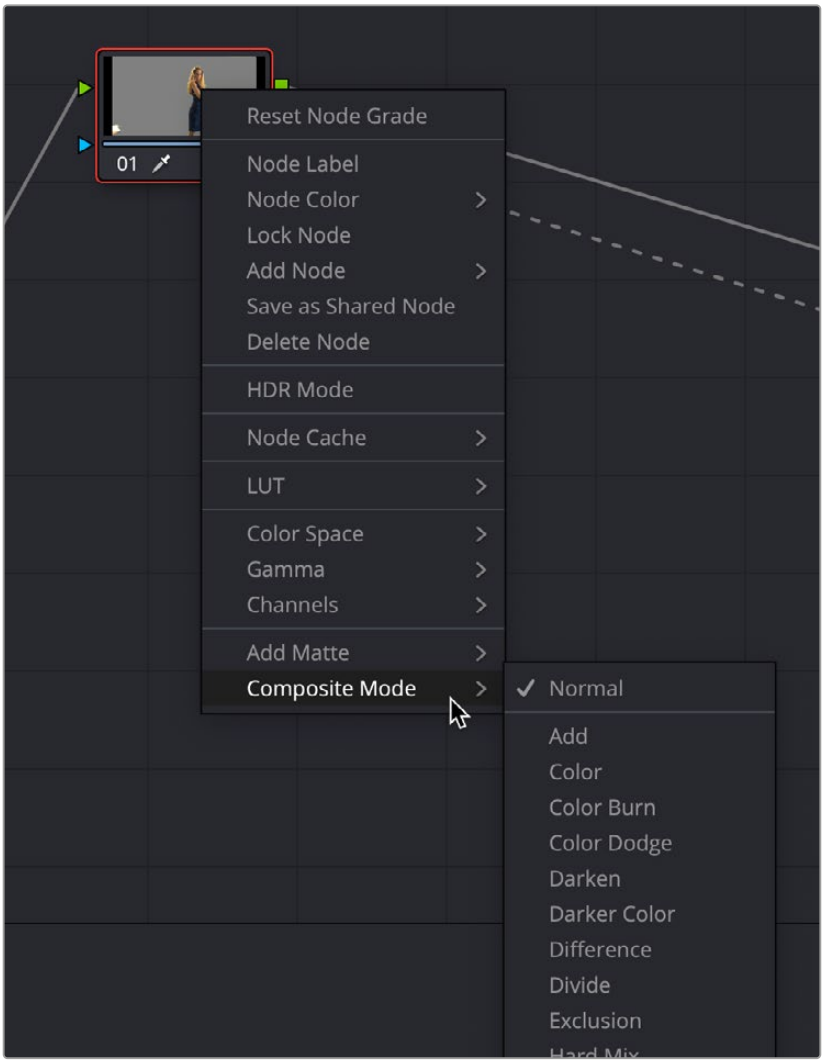
Using an external matte in the grade and to the Alpha output

You should now see a successful composite, with the external matte creating a region of transparency in the foreground clip through which the background clip shows through.

Before and after the final composite, created by connecting an EXT MATTE node to the Alpha output in the node graph

Setting the Composite Mode in a Corrector Node

If you are compositing in the Color page using the Alpha output, you can set a specific composite mode for any corrector node. Right-click the node and select Composite Mode from the contextual menu. You can then change the type of composite for the node to any of DaVinci Resolve's built-in composite modes.



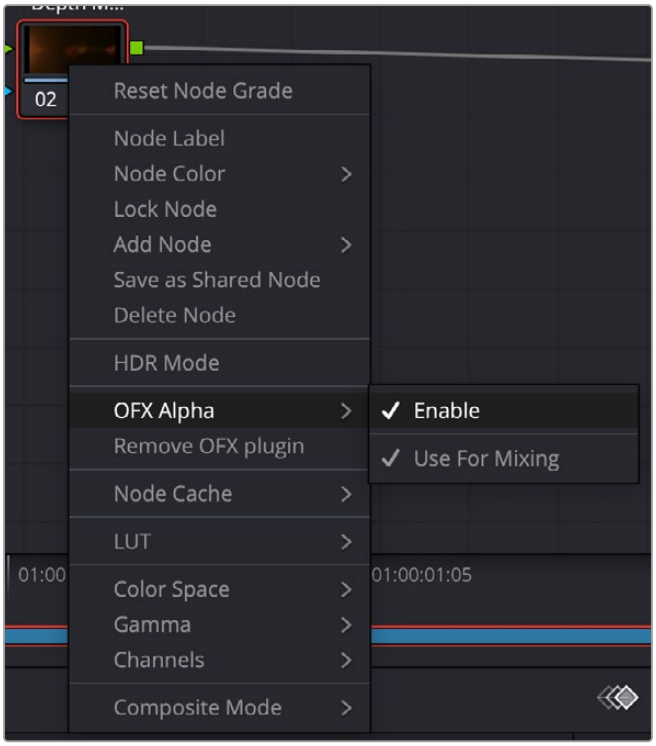
Choosing a Composite mode for the Corrector node

Using OFX Alpha Channels (Legacy)

Now that all effects use standard color corrector nodes, the OFX Alpha is always available without having to manually set a menu option. There is no need for the user to do anything else to access an OFX Alpha moving forward from DaVinci Resolve 18.5.

However, for legacy project use there is still an OFX Alpha menu with two options.

- **Enable:** On by default. When this is unchecked, even if the effect generates an Alpha, the Alpha is ignored. Why one would go to the bother of generating an effect with an Alpha channel, only to discard it completely is a matter of conjecture, but the option is there if you're doing something exceedingly strange and complicated. Really just leave this on.
- **Use For Mixing:** On by default. When unchecked, no mixing of the Alpha happens on the node at all. Power Windows and Keys stop working, and the node behaves like a legacy FX node. Any Alpha generated is still output, it just doesn't limit where the effect acts.



The Use OFX Alpha option has been replaced with the OFX Alpha menu. You most likely want to keep both Enable and Use for Mixing checked unless you have a really good reason.

Chapter 146

Keyframing in the Color Page

The Color page has a dedicated Keyframe Editor, found at the right of the palette area, that you can use to animate grading changes from one frame to another. Because grading is a fundamentally different task than editing, the Color page Keyframe Editor operates somewhat differently from the Curve Editor in the Edit page.

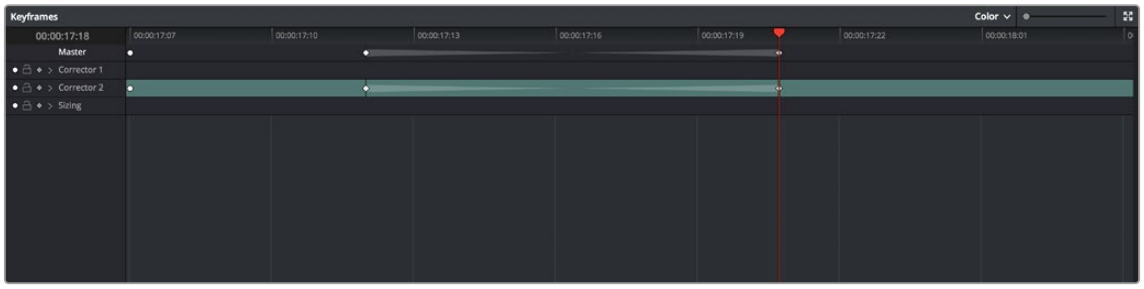
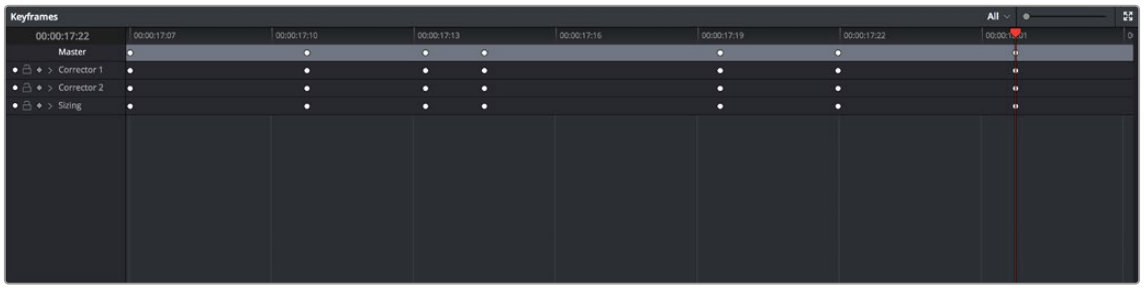
Introduction to Keyframing

Whether it's referred to as keyframing, dynamics, or marks, DaVinci Resolve provides an interface for automatically interpolating color adjustment parameters in various ways from one setting to another. For example, if you have a clip with varying exposure settings, you can animate a series of contrast adjustments using Dynamic keyframes to make the changes in exposure less distracting.



The Keyframe Editor with dynamic keyframes animating the parameters of Node 2

In another example, suppose you're grading a documentary, and an archival clip that's edited in the middle of the Timeline actually consists of six different shots from a program in the eighties. If you're in a hurry, you can insert Static keyframes (marks) at the cut points of each of these shots, creating instant one-frame transitions between different adjustments made to that clip's grade, which allows you to create unique adjustments for each shot within the clip.

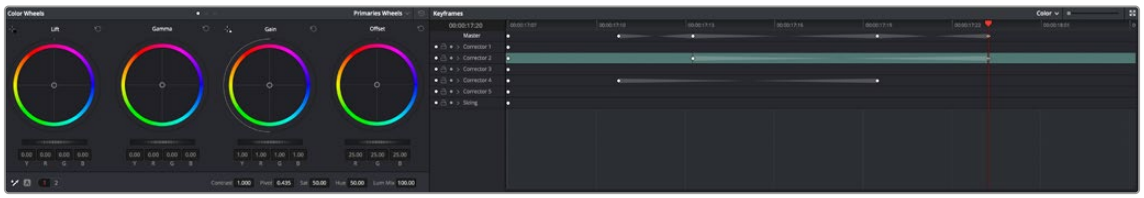


Round static keyframes added to all parameters, enabling individual adjustment of shots merged together within a single clip

In both cases, you use the Keyframe Editor to create a series of keyframes with which to change parameters from one value to another. In this section, you'll learn how to work with the Keyframe Editor to set up these kinds of animated changes.

The Keyframe Editor Interface

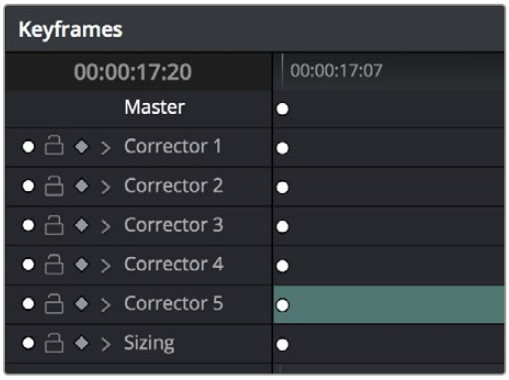
The Keyframe Editor has all the controls necessary to create and modify keyframes for the currently selected clip. If necessary, you can even make it wider in a single screen layout by clicking its expand button (at the top right of the Keyframe Editor). If you have two computer displays, you can use the Color page's Dual Screen layout which places the Keyframe Editor on a second screen and uses the entire width of the monitor, for even more room.



The Node Editor shown in wide mode, pushing all other palettes to the left

The Keyframe Editor consists of the following components:

- **Timeline Ruler:** Mirrors the record timecode of the currently selected clip; dragging within the Timeline Ruler moves the playhead, and a timecode display to the left shows the current frame.
- **Keyframe track header:** Each node in the current grade has a corresponding keyframe track, Sizing has its own keyframe track, and the track header contains controls you can use to manage the keyframing.



The Keyframe track header

- **Enable/Disable button:** A round white button lets you enable or disable that track's corresponding node.
- **Lock button:** Lets you prevent any changes from being made to that track's corresponding node. Nodes that have been locked show a lock icon. You can also lock or unlock nodes by right-clicking a node in the Node Editor and choosing Lock Node from the contextual menu.

Nodes 1 and 2 have been locked in the Keyframe Editor of the Color page.

- **Auto-Keyframe button:** Turn this button on to automatically create a Dynamic keyframe every time you adjust any parameter within that node.
- **Track disclosure triangle:** Exposes individually keyframable groups of parameters underneath the main keyframe track.

- **Keyframe tracks:** To the right of the track header, the keyframe tracks are where you create and edit the keyframes that animate parameter changes. A topmost “master keyframe track” shows every keyframe applied on every keyframe track in the Keyframe Editor, even keyframes applied to a keyframing track hidden inside a track with a closed disclosure triangle.
- **Keyframes:** Each keyframe appears as a small diamond for a Dynamic keyframe or as a circle for a Static keyframe. Dynamic keyframes are associated with dissolves while Static keyframes (marks) act instantly. Grades are linked to the preceding keyframe, which may be a default one on the first frame of the master clip. Keyframes can be selected by clicking on them, or moved by dragging them to another position in the keyframe track.
- **FX track:** Resolve FX or OFX plugins that have been added to a grade as a standalone node have a separate track for creating animated effects. Every parameter of that track is keyframed via a single consolidated keyframe track. If you apply multiple plugins as multiple nodes, each has a separate FX track.
- **Sizing track:** The Pan, Tilt, Zoom, Rotate, and Convergence (in Stereo 3D projects) parameter have an entirely separate track for creating animated pan and scan adjustments.
- **Track selection drop-down:** A colored bar shows the currently selected scope of keyframing: all tracks at once, just the current correction node, or the Sizing settings, as defined by the Keyframe Timeline mode discussed in the next section.

Ordinarily, the Keyframe Editor takes up the rightmost bottom third of the Color page. However, you can make it wider to have more room to work if you have a scene requiring complex keyframing.

To expand and collapse the Keyframe Editor:

- Click the Expand/Collapse button at the top right corner of the Keyframe Editor. The Keyframe Editor widens or narrows accordingly.

To zoom into and out of the keyframe tracks:

- Use the Zoom slider to zoom into or out of the Keyframe Editor.
- Right-click any keyframe track and choose Maximum Zoom to zoom all the way in.
- Right-click any keyframe track and choose Reset Zoom to fit the entire clip into the available width of the Keyframe Editor.

All/Color/Sizing

Perhaps the most important control for keyframing, the Keyframe Timeline mode, lets you switch the scope of what tracks get keyframed when you use the Start Dynamic or Add Static Keyframe commands, either from the keyboard or via the buttons of your control panel. This command alternates among three modes:

- **All:** The default mode. Adds keyframes to every track in the Keyframe Editor, keyframing every parameter in every node all at once, including the Sizing settings. In this mode, an orange bar appears highlighting the topmost “master keyframe track.”
- **Color:** Only adds keyframes to the node currently selected in the Node Editor. In this mode, a green bar appears highlighting the keyframe track corresponding to the node currently selected.
- **Sizing:** Only adds keyframes to the Sizing track, which is useful when you’re keyframing “pan and scan” style transforms. In this mode, a blue bar appears highlighting the Sizing track.
- **EXT MATTE:** Only appears if there’s an external matte node in the node tree. Lets you keyframe external matte-specific parameters in the Key palette.

Even though All is the default setting, it may be to your advantage to switch to the Color or Sizing keyframing modes to avoid creating a lot of unnecessary keyframes. Even though keyframing everything all at once is a fast way to work, the extra keyframes may slow you down when you later need to make adjustments to nodes that didn't need to be keyframed in the first place.

To change the keyframing mode, do one of the following:

- Choose an option from the Keyframe mode drop-down at the top right of the Keyframe Editor.
- Choose an option from the Mark > Keyframe Timeline mode submenu.

TIP: This control has one other function. Choosing a mode also affects what is copied when you use the various grade management tools in DaVinci Resolve. For example, if you choose Color, then you can copy a clip's color grade without copying its sizing. If you choose Sizing, then you can copy the sizing without copying the color grade.

For more information, refrer to "Copying Grades" *see Chapter 140, "Grade Management."*

Keyframing Methods

There are two different types of keyframes used by DaVinci Resolve to create automated changes. Each type of keyframe interpolates parameters differently.

Dynamic Keyframes (Dynamics)

Dynamic keyframes are the most conventional type of keyframe you'll use, and are the type of keyframe used for creating animated changes from one state to another. For example, if you need a grade to become brighter over time to compensate for a change in lighting conditions, you'll use Dynamic keyframes.

Nearly every parameter and control in the Color page can be keyframed, but it's important to understand that the Interface controls do not animate to match whatever dynamically keyframed changes are taking place. Instead, visible Interface controls that correspond to keyframed changes will jump from their initial position at one keyframe to their final position when the playhead reaches the next keyframe.

This can be most confusing with Curves, which can be interpolated using Dynamic keyframes just like any other control or parameter. Just keep in mind that the actual settings are animating, even though the controls are not.

To animate a node using Dynamic keyframes:

1. Move the playhead in the Keyframe Editor's Timeline ruler to the frame where you want to begin a change.
2. Do one of the following to place a Dynamic keyframe at that frame:
   - Choose Mark > Add Keyframe (Command-[).
   - Turn on the Auto Keyframe button for the track you want to animate in the Keyframe Editor.

   Dynamic keyframes are diamond-shaped.
3. If necessary, adjust your clip at this first position of your animated change. If you're using Auto Keyframe, then you have to make an adjustment for a keyframe to be created.

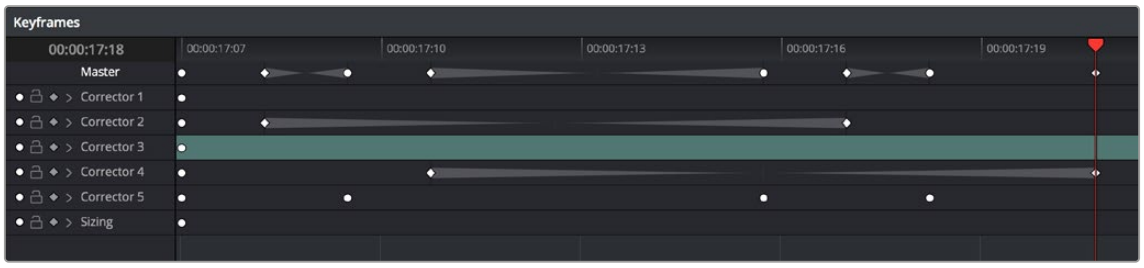
4 Now, move the playhead to the frame that is at the second position of the animated change you're making, and create another Dynamic keyframe if you're creating keyframes manually, or make another adjustment if Auto Keyframe is on.

5 After you've created this second keyframe, make whatever adjustments are necessary to the clip to create the final look you need.

At this point, playing from the first keyframe to the second keyframe should show a smoothly animated change from the first adjustment to the second. When you're finished, make sure you turn Auto Keyframe off if it was enabled.

Static Keyframes (Marks)

Static keyframes, or marks, are keyframes that are used to create abrupt, one frame changes from one state to another. They're typically used to mark edit points separating one shot from another when multiple shots appear within a single clip. However, Static keyframes are also useful in any situation where you need a sudden change from one setting to another, such as when creating a lightning effect.



Static keyframes are round.

To automate a node using Static keyframes:

1 Find the frame at which you want the abrupt change to take place, and place a keyframe at that frame by doing one of the following:

- Choose Mark > Make Static Keyframe (Command-]).
- Static keyframes (marks) are round.

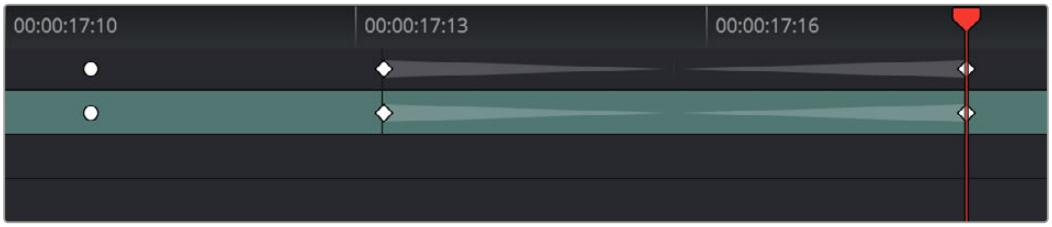
2 Move the playhead to any frame before the keyframe to make changes to the entire segment of the clip leading up to the keyframe, or move the playhead to any frame after the keyframe to make changes to the entire segment of the clip appearing after the keyframe. The playhead does not need to be on top of the keyframe, but if it is, you'll be adjusting the second portion of the clip.

NOTE: If you're using Static keyframes to automate grading changes between multiple shots appearing within a single clip, keep in mind that you can't add nodes from one keyframe to the next as you would if you had split the clip in the Edit page.

Mixing and Converting Dynamic and Static Keyframes

Typically, if you're creating multiple animated changes within a clip, you'll want to use all Dynamic keyframes. Similarly, if you're creating a series of abrupt changes, you'll use all Static keyframes. However, you can mix Dynamic and Static keyframes together, so long as you keep in mind the following rules:

- **If you add a Dynamic keyframe to the right of a Static keyframe:** There will be no interpolation from the Static keyframe to the Dynamic keyframe. However, if you add a Static keyframe to the right of a Dynamic keyframe, there will be interpolation.



No dynamic interpolation following the static keyframe

If you accidentally create the wrong kind of keyframe, it's easy to convert it into the type of keyframe you need.

To change one kind of keyframe into another:

1. Click the keyframe you want to convert to select it.
2. Right-click the selected keyframe, and choose either Change to Dynamic Keyframe or Change to Static Keyframe.

Try Creating Keyframed Changes in a Separate Node

One tip to keep in mind is that you don't have to create keyframed changes within the same nodes you're using to create other adjustments. If you want to create some automated changes without altering the nodes you've already adjusted, you can simply create a new node in which to make your keyframed changes. That way, if you don't like the result, or you somehow find yourself hopelessly tangled up in a needlessly complicated set of keyframes, it's easy to reset either just the keyframes or the entire node without affecting the rest of your grade.

Keyframed Nodes Have a Badge

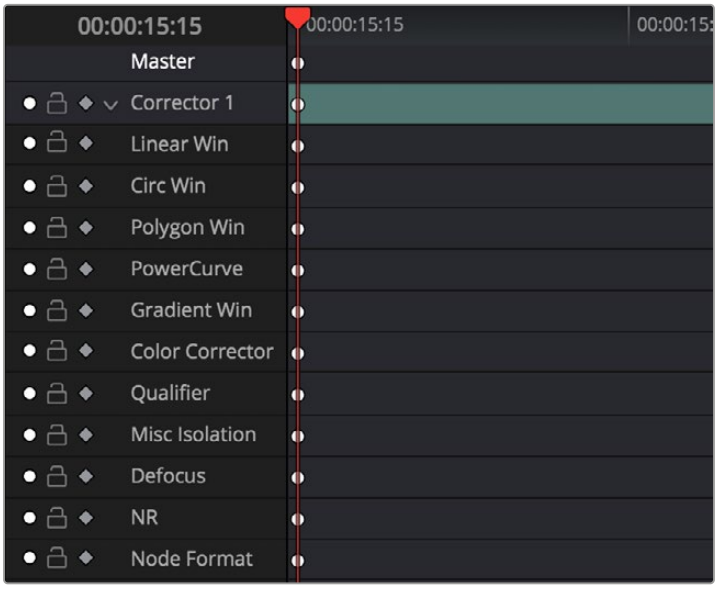
Nodes with keyframed parameters display a keyframe badge in the Node Editor, to make them easy to find. Note that keyframe badges won't appear when you simply add a keyframe but only once there's an actual keyframed adjustment being made.

Keyframed nodes display a badge in the Node Editor.

Using Specific Keyframing Tracks

If you're simply using the Color mode of the All/Color/Sizing command to do keyframing, then you'll be adding keyframes to every parameter of the currently selected node whenever you apply a single keyframe. However, often that's overkill in situations where you only need to keyframe a single setting or group of settings.

For example, you may find that you need to keyframe a color adjustment in order to change the color temperature and brightness when the camera pans across a window, but you don't want to keyframe the Windows palette controls because you want to adjust them independently. This can be done by opening a Corrector track to expose the keyframing tracks within.



Individual keyframing tracks within a Color Corrector node

Keyframing tracks let you keyframe different sets of similarly functioning parameters separately from one another. For example, there's one keyframing track for all the color adjustment parameters, and another keyframing track governing the parameters found within the Qualifier palette.

To reveal a node's keyframing tracks:

- Click the disclosure triangle next to the number of the node you're keyframing.

To keyframe an individual keyframing track manually:

1. Make whatever adjustments you need to the currently selected node, and click its disclosure triangle to reveal its keyframing tracks.
2. Move the playhead in the Keyframe Editor to where you want to add the first keyframe, then right-click within the keyframing track you want to animate, and choose Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).

   A keyframe appears at the position of the playhead in that keyframing track.
3. Move the playhead in the Keyframe Editor to where you want to add the next keyframe, then right-click within the keyframing track and again choose either Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).

Keyframing just the Circular Power Window using its individual keyframe track

Now, you can make whatever changes you need to the controls governed by the keyframing track you keyframed, in order to create the necessary animated effect.

TIP: You can also animate individual keyframing tracks using automatic keyframing, explained in more detail later in this chapter.

Corrector Keyframing Tracks

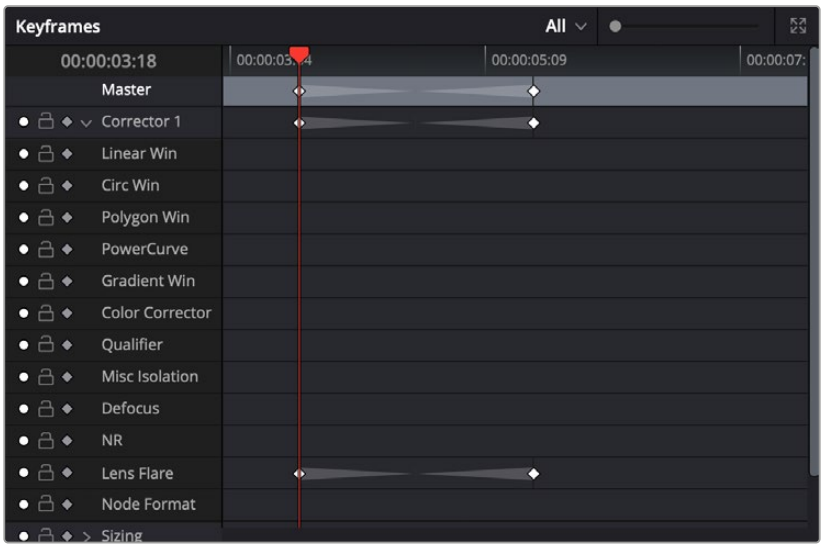
All of the parameters governing the adjustment of color and contrast controls, as well as various effects, Power Windows, and other adjustments are sorted into various sub-tracks within the Corrector track.

- **Linear Win:** Controls parameters corresponding to the Linear window.
- **Circ Win:** Controls parameters corresponding to the Circular window.
- **Polygon Win:** Controls parameters corresponding to the Polygon window.
- **PowerCurve:** Controls parameters corresponding to the PowerCurve window.
- **Gradient Win:** Controls parameters corresponding to the Gradient window.
- **Color Corrector:** Controls all parameters found in the Camera Raw, Color Wheels, Primary Controls, RGB Mixer, and Curves palettes.
- **Qualifier:** Controls all parameters in the Qualifier palette.
- **Defocus:** Controls all parameters in the Blur and Key palettes.
- **NR:** Controls the Spatial and Temporal Noise Reduction and Motion Blur parameters found in the Motion Effects palette.
- **Open FX:** Controls all parameters of whichever OFX plugin is applied to the current node.
- **Node Format:** Controls all parameters of the node sizing mode of the Sizing palette for the current node.

ResolveFX Keyframe Tracks

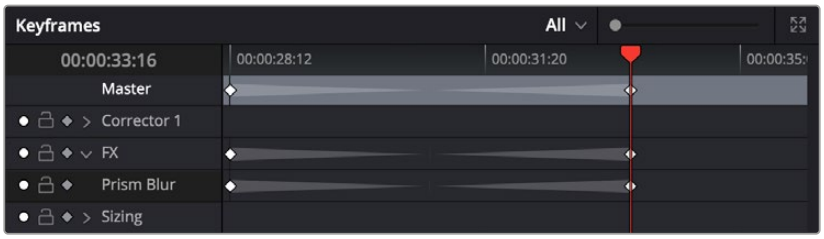
The Color Page Keyframe Editor supports viewing and editing keyframes for ResolveFX and OpenFX plugins in the Color page in one of two ways:

- Plugins that have been added to a Corrector node appear within the hierarchical list of keyframe tracks that appear within that node's top-level keyframe track.



The keyframe track of a Resolve FX plugin added to a Corrector node

- Plugins that have been added as standalone nodes appear within a new FX track of the Keyframe Editor. Each plugin that's added as a separate node has a separate FX track.



The keyframe track of a Resolve FX plugin added as a standalone node

The Sizing Keyframing Tracks

The Sizing keyframing tracks govern sizing transforms and stereoscopic adjustments separately from the color controls.

- **Input Sizing:** Controls the Input Sizing parameters found within the Sizing palette.
- **Convergence:** Controls the Convergence parameter in the Stereo 3D palette.
- **Float Window:** Controls the Left, Right, Top, and Bottom Position/Rotate/Softness Floating Windows parameters.
- **Auto Align:** Controls the Pitch and Yaw parameters in the Stereo 3D palette.

TIP: Output Sizing can only be keyframed when you choose Timeline mode in the Node Editor.

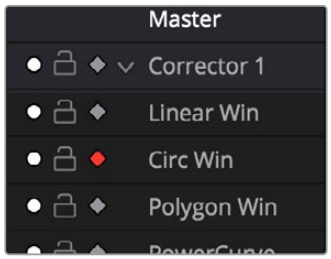
The Ext Matte Node's Freeform Isolation Track

If your node tree has an External Matte, the EXT MATTE node exposes a Freeform Isolation track in the Keyframe Editor. This is useful for time offsets or Sizing repositioning of the Ext Matte image.

Automatic Keyframing

Every track in the Keyframe Editor has an Auto-Keyframing button that can be turned on or off. When auto-keyframing is enabled for a particular track, every change made to a parameter or control associated with that keyframe track automatically generates a keyframe. There are two ways you can use this:

- Used with a keyframing track, auto-keyframing makes it simple to set up animated changes to specific adjustments within a node. This is a lot easier than manually placing keyframes one by one.
- On the other hand, turning on auto-keyframing for the Corrector track correspondingly enables auto-keyframing for every keyframing track belonging to that node. In this case, keyframes will automatically be placed on whatever keyframing track corresponds to the parameters or controls you adjust.



Auto-keyframing selected for Circular window on Node 1

When auto-keyframing is disabled, changes you make alter existing keyframes. How this alteration works depends on the location of the playhead, and the type of keyframes in the Keyframe Editor. For more information, see the next section.

Modifying Keyframes

Once you've started adding keyframes to animate changes to a grade, there are a variety of methods available to navigate and edit these keyframes to further customize these effects. This section covers the different ways you can navigate among, alter, and remove keyframes.

Navigating Among Keyframes

For many operations, it's necessary to move the playhead directly on top of the keyframe you want to modify. While you can always use the transport controls or pointer to move the playhead, there are also commands for jumping to a specific keyframe.

To move the playhead among a series of keyframes:

- Choose Playback > Next > Keyframe (the right bracket key) or Playback > Previous > Keyframe (the left bracket key).

Moving Keyframes

If you need to change the timing of a series of keyframes, you can move the position of any keyframe, along with whatever values that keyframe contains.

To move a single keyframe using the onscreen interface:

- Use the pointer to drag any keyframe to another location.
- Drag keyframes in a top-level Corrector or Sizing track to simultaneously move all other keyframes on the same frame within that corrector.

To move multiple keyframes at the same time:

1. If necessary, open the keyframe track with the keyframes you want to move.
2. Drag a bounding box around the keyframes you want to move. Selected keyframes appear highlighted in red.
3. Drag any of the selected keyframes to move them to the left or right.

Changing Keyframe Values

Unlike many other applications, DaVinci Resolve lets you alter keyframe values when the playhead isn't directly on an existing keyframe. How this works depends on the location of the playhead relative to the keyframes that are in the Keyframe Editor, and what kind of keyframes you're editing.

- **If the playhead is to the left or on the first Dynamic keyframe:** The Dynamic keyframe at or to the right of the playhead updates with the new adjusted values.
- **If the playhead is to the left or on the last Dynamic keyframe:** The Dynamic keyframe at or to the left of the playhead updates with the new adjusted values.
- **If the playhead is between two Dynamic keyframes:** The Dynamic keyframe to the left of the playhead updates with the new adjusted values, but the Dynamic keyframe to the right is unaffected.
- **If the playhead is between two Static keyframes (marks):** Adjustments made between two Static keyframes always affect the keyframe to the left of the playhead. The entire segment of the clip between that keyframe and the next is affected equally.

Changing Dynamic Attributes

By default, the transition from one Dynamic keyframe to the next is linear. However, if you need to alter the acceleration of value interpolation from one Dynamic keyframe to the next, then you can change that keyframe's dynamic attributes.

To change a keyframe's dynamic attributes:

1. Click to select a keyframe in the Keyframe Editor.
2. Right-click the selected keyframe, and choose Change Dynamic Attributes.
3. When the Dynamic Attributes window appears, do one or both of the following:
    - Choose a new outgoing acceleration curve using the Start slider, affecting the interpolation occurring to the right of that keyframe.
    - Choose a new incoming acceleration curve using the End slider, affecting the interpolation occurring to the left of that keyframe.

    As you choose different acceleration curves, the display to the right shows the resulting curve graph.

Changing the dissolve profile

4 When you're happy with the curve, click OK.

By using different Start and End values, you can make animated adjustments "ease in" or "ease out" of a particular keyframe, to create a more gradual or abrupt transition.

TIP: The default dynamic profile start and end of each new keyframe can be set via the Dynamics Profile values in the General Options panel of the Project Settings.

Deleting Keyframes

You have the option to delete individual keyframes, or to delete all the keyframes within a particular grade at once.

To delete individual keyframes, do one of the following:

- Move the playhead on top of the keyframe you want to delete, then choose Mark > Delete Keyframe (Option-]). Every keyframe at the position of the playhead is deleted.
- Using the pointer, click a keyframe in the Keyframe Editor to select it, then right-click that keyframe and choose Delete Selected Keyframe. Only the selected keyframe is deleted.

To delete every keyframe for the current clip:

- Choose Mark > Delete All Keyframes.

Copying Keyframes

It's possible to copy a set of keyframes from one node to another, either within the current grade, or in another clip entirely. It's also possible to copy an entire grade with keyframes from one clip to another.

To copy a set of keyframes from one node to another:

1. Select a node to copy keyframes from, and choose Edit > Copy (Command-C).
2. Do one of the following:
   - To copy all keyframes, select another node to paste keyframes and other adjustments to, and choose Edit > Paste (Command-V).
   - If you want to just copy only the keyframe information from a specific keyframe track, choose Edit > Paste Attributes (Option-V), then click the "Copy Keyframes and Align Using" checkbox, and select the appropriate parameters to copy.

> **TIP:** This procedure also works for tracking data that you want to copy from one node to another, either in the current clip, or another clip altogether.

To copy an entire grade with keyframes from one clip to another:

1. Click the thumbnail of the clip you want to copy to in the Thumbnail timeline.
2. Right-click the thumbnail of the clip you want to copy from, and choose Apply Grade from the contextual menu.

> **NOTE:** When copying a grade with keyframes from one clip to another, the keyframes will automatically be placed at matching frames that correspond to the source timecode of the originating clip. This makes it easy to copy a grade with keyframes to the same clip elsewhere in the Timeline, but it may not provide the desired results if you're applying a grade with keyframes from one clip to a completely different one.

Keyframes and Saved Stills

If you save a still from a clip using keyframes within the grade, by default keyframes are not saved. However, the still and grade that are saved reflect whatever parameter values are contained by the next keyframe to the left of the position of the playhead. For example, if a clip has a dynamically keyframed transition from a saturation of 50 to a saturation of 0, and you place the playhead right in the middle of both keyframes when you save a still, the grade and still that are saved have a saturation of 50.

However, if you right-click the background of the Gallery, choose one of the options within the "Apply Grades Using" submenu, and choose the appropriate "Keyframes Aligning..." options, then grades saved within a still are saved with the keyframes, which reference the source timecode, or start frame of the original clips. This means that if you apply a saved grade with keyframes to a clip, the keyframes will automatically be placed at matching frames that correspond to the source timecode or start frame of the original clip. This makes it easy to copy a grade with keyframes to the same clip elsewhere in the Timeline, but it may not provide the desired results if you're applying a grade with keyframes from one clip to a completely different one.

Adding EDL Marks

Just as clip grades are separate from the timeline grade that can be applied to the entire Timeline, so clip keyframes are separate from timeline keyframes. Keyframes you apply to the timeline grade work exactly the same as clip keyframes. However, there is one extra option you have when keyframing the timeline grade.

If you find yourself wanting to adjust a timeline grade individually to take into account variations from one clip to the next, you can use the Add EDL Marks on Tracks command to add a Static keyframe (mark) to the Keyframe Editor at the position of every edit point in the entire Timeline.

To add EDL marks:

1. Choose Timeline from the Node Editor's mode drop-down menu.
2. If you want to keyframe a grade, then create whatever grade you need to apply to the entire Timeline. If you want to keyframe Sizing settings, you don't need to do anything else.
3. Right-click the Corrector track or the Sizing track in the Keyframe Editor, and choose Add EDL Marks on Tracks.

   Marks appear at the frame of every edit point in the Timeline. You may want to widen the Keyframe Editor to make it easier to work with all these keyframes.

   After you've added EDL marks, you can delete them if you decide you don't want them any more.

To delete EDL marks:

- Right-click the Corrector track in the Keyframe Editor, and choose Delete EDL Marks on Tracks.

If you've added your own keyframes in addition to the EDL marks, then the Delete EDL Marks on Tracks command only eliminates the EDL marks. Your custom marks are left alone.

Chapter 147

Copying and Importing Grades Using ColorTrace

ColorTrace is a key feature of DaVinci Resolve, which lets you copy grades quickly and easily from the clips of one timeline to those within another, based on the source timecode of each clip (or using clip names when in Automatic mode).

You can even use ColorTrace to copy grades between timelines within the same project, and ColorTrace one stereo timeline to another.

Contents

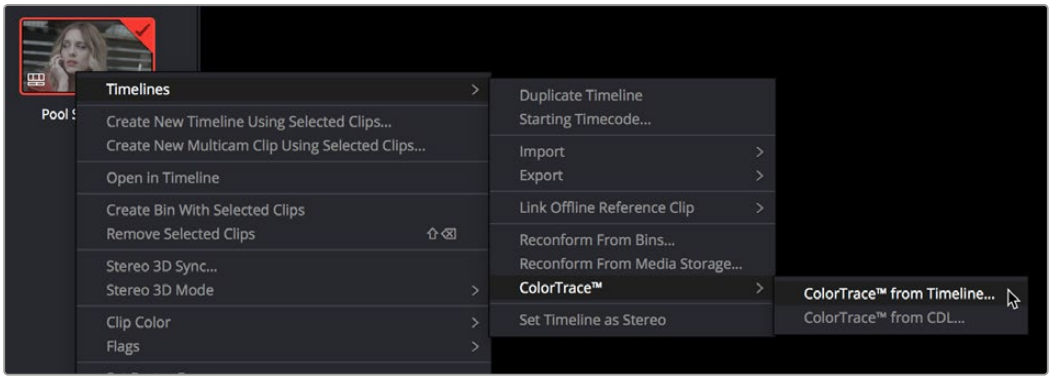
Copying Grades Using ColorTrace 3243
Using ColorTrace in Automatic Mode 3244
Using ColorTrace in Manual Mode 3247
Importing CDL Data Using ColorTrace 3249
Using CDL Adjustments 3251
Calculating CDL Functions 3251

Copying Grades Using ColorTrace

ColorTrace copies whichever version of a clip's grade was applied in the Source timeline you're copying from, either local or remote, depending on which grades each clip in the Source timeline is set to use. Furthermore, ColorTrace copies Group Pre-Clip and Group Post-Clip grades, as well as Fusion compositions. These improvements make this an extremely reliable tool for copying grades from one timeline to another in a wide variety of situations.

To use ColorTrace:

1 Open the Edit page and select the Timeline you want to use ColorTrace with from the Media Pool, then open it and choose Timelines > ColorTrace > ColorTrace From Timeline.

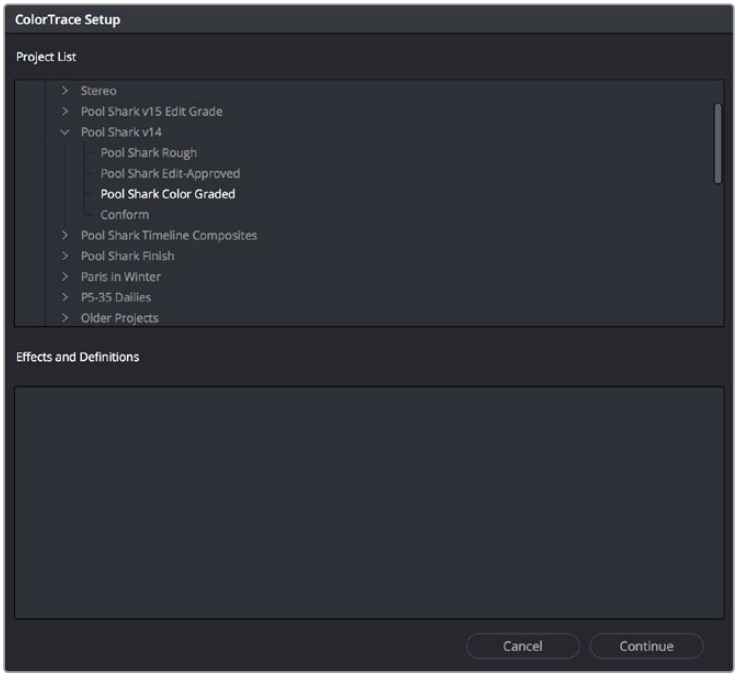


Choosing ColorTrace for a selected Timeline

The ColorTrace Setup window appears, which shows every project library, user, project, and timeline within a single hierarchical list.

2 Using the Project List browser, select the specific Timeline you want to copy grades from.

You'll need to click the disclosure triangle to the left of the project library, user name, and project that contains that Timeline in order to select it.



ColorTrace project and Timeline selection window

3 (Optional) If you're using ColorTrace with a project that has numerous VFX clips in a workflow where all VFX clips have specific reel names that identify them, you can enter these names (with asterisks (*) used as wildcards that indicate text in each reel name that can vary) in the "Effects Shot Definitions" field.

This speeds automatic ColorTrace operations by enabling DaVinci Resolve to use fuzzy string matching when a clip's reel number qualifies it as a VFX shot so that the best match is displayed first on the list. You can enter multiple VFX reel names with wildcards, one per line, for simultaneous string matching. You can use whatever reel name text makes sense for your workflow, some examples of VFX reel names are as follows:

```
*_COMP_*
VFX*
EFFECTS*
```

4 Click Continue.

The ColorTrace window appears with two tabs that let you choose how to work.

5 Choose which mode to work in by clicking the Automatic or Manual tab:

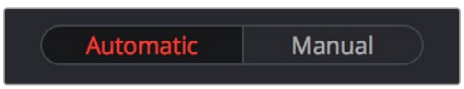
- In Automatic mode, ColorTrace automatically searches for matching clips between the selected Timeline and the current Timeline. Each clip is color coded depending on the correspondence that's been identified.
- In Manual mode, you copy grades yourself, using the Copy and Paste procedures, or by dragging and dropping using your mouse.

The ColorTrace window is complex; details about the operation of each mode are covered separately in the following sections.

6 When you're finished using ColorTrace, click Close.

Using ColorTrace in Automatic Mode

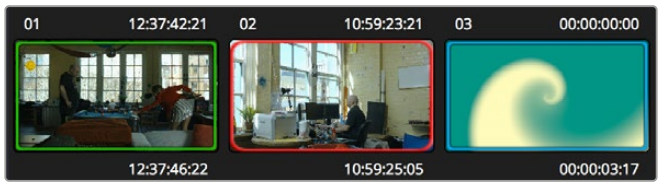
In Automatic mode, ColorTrace automatically finds the correspondences between clips in the selected Timeline that you want to copy grades from (the Source timeline), and those in the current Timeline that you want to copy grades to (the Target timeline).



Selecting the Automatic or Manual ColorTrace

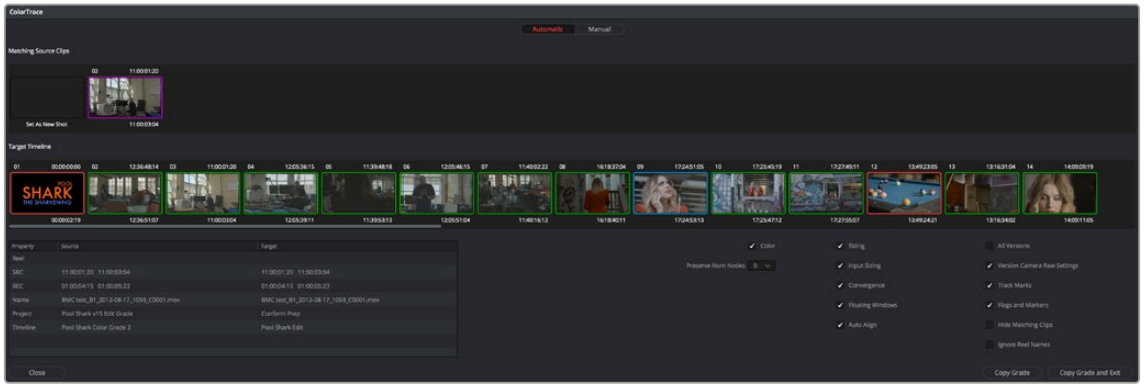
Each clip in the Target Timeline Thumbnail timeline is outlined with a color that indicates its status.

- **Red:** No match was found at all. Generally true for clips in the current Timeline that weren't used in the Timeline you're ColorTrace matching to.
- **Blue:** Due to overlapping timecode and reel names, multiple correspondences have been found (similar to a reel conflict), and you must select the correct one for each clip. This often happens with VFX and motion graphics clips that you've imported with timecode starting at 00:00:00:00.
- **Green:** A match has been found.



ColorTrace Thumbnail outlines indicate matching, overlapping, and non matching clips.

In Automatic mode the correspondence between each clip in the Source timeline and each clip in the Target timeline should be automatically made. However, overlapping timecode and reel names can cause problems. The other controls in the ColorTrace window help you deal with the subset of clips that can't be automatically matched, or are matched in error. These controls are:



The ColorTrace window shown in Automatic mode

- **Matching Source Clips list:** Shows a scrollable collection of thumbnails that might correspond to the selected clip in the Target timeline.
- **Target Timeline:** Shows each clip in the Timeline you want to copy grades to, color coded according to how good a match it is.
- **Clip Info pane:** Displays two columns of properties for the source clip and the target clips that you've selected. These properties include the reel, source timecode, record timecode, clip name, project names, and timeline names of each clip, for easy comparison.
- **Attributes and options checkboxes:** A series of checkboxes lets you specify which clip attributes are copied as part of the ColorTrace operation.
- **Color:** Enables the copying of grades.

  Preserve Num Nodes: When copying grades, lets you prevent the first X nodes of the target clip grades from being overwritten by the first X nodes of the source clip grades.

  Input Sizing: Enables the copying of Input Sizing attributes.

  Convergence: Enables the copying of Convergence for Stereo 3D projects.

  Floating Windows: Enables the copying of Floating Windows for Stereo 3D projects.

  Auto Align: Enables the copying of Auto Align settings for Stereo 3D projects.

  All Versions: Copies all versions, rather than just the current version, from the source to the target clips. The currently selected version of each source clip is always correctly copied.

  Version Camera Raw Settings: Enables the copying of versioned Raw settings, rather than just the current Raw setting.

  Track Marks: Enables the copying of keyframes.

  Flags and Markers: Enables copying of all flags and markers.

Hide Matching Clips: Hides all clips which have been successfully matched, and only show the clips with multiple or no matches. This lets you focus on the subset of problem clips within a potentially long timeline.

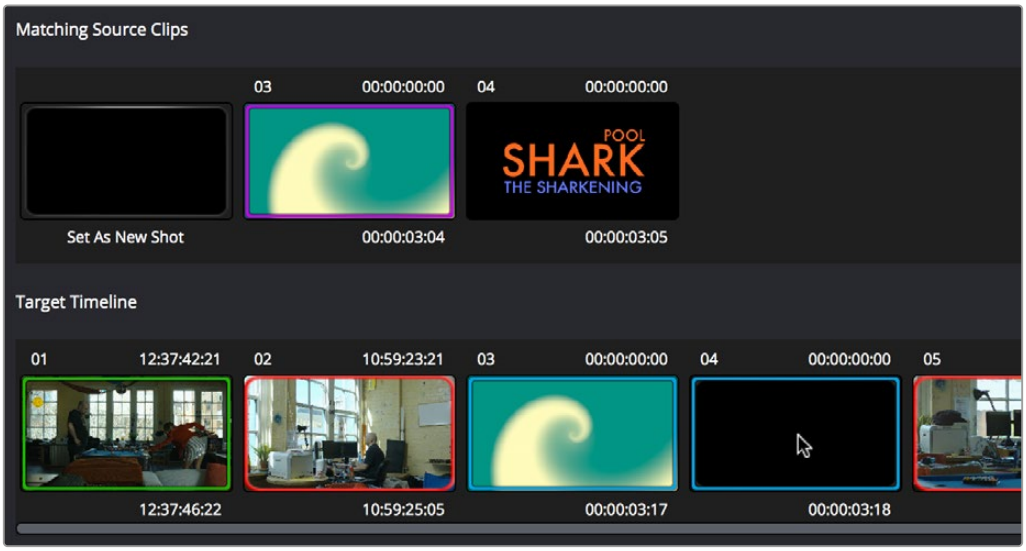
Ignore Reel Names: If you believe the reel names are in error, you can turn this checkbox on to ignore them, matching all source and target clips by timecode alone.

- **Copy Grades:** Copies the matched source grades to each green and purple target clip.
- **Copy Grades & Exit:** Once you've finished making all the grade matches you can, click this button to copy the matched source grades to each green and purple target clip, and close the ColorTrace window.

Here's how to use these controls to sort out which source clips to copy from for each blue and red target clip in the Target timeline.

To manually choose which source grades should be copied to which target clips:

1 Click any blue clip thumbnail in the Target timeline.



Revealing a number of different possible correspondences in the Matching Source Clips Timeline

A collection of clips with overlapping timecode and reel names appears. If you want to ignore the reel names because you believe they might be in error, turn on the Ignore Reel Names checkbox.

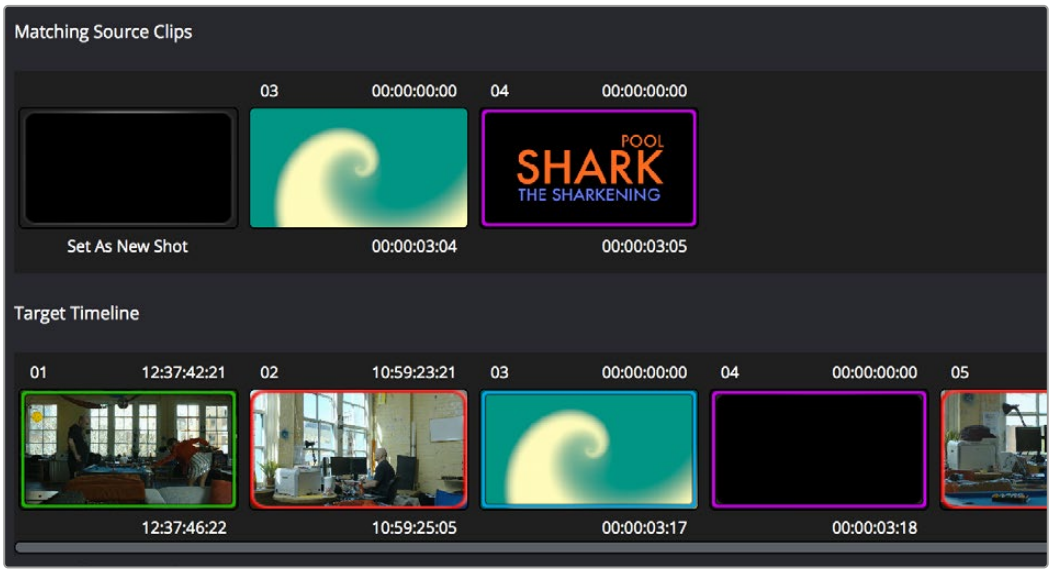
2 If a comparison of the Source and Target thumbnails doesn't make the choice obvious, then click any of the clips in the Matching Source Clips timeline to view its metadata for comparison in the source/target columns below.

Property	Source	Target
Reel		
SRC	00:00:00:00 00:00:03:05	00:00:00:00 00:00:03:18
REC	01:00:27:11 01:00:30:16	01:00:27:11 01:00:31:05
Name	Pool Shark Title.mov	Pool Shark Title.mov
Project	Pool Shark	Pool Shark Editing Refinement
Timeline	Pool Shark (Trimming)	Pool Shark (Trimming)

Source and Target clip metadata for comparison

3 Once you've decided on a clip correspondence, double-click the Matching Source Clip thumbnail you want to copy from. If no clip in the Matching Source Clip pane is a good match, double-click the "Set As New Shot" box.

The Source and Target thumbnails both turn purple, to show that you've created a correspondence.



The matching Source and Target clips now both marked with purple outline

Continue working your way through every thumbnail with Blue and Red Xs until you've found matches for every clip in the Timeline for which it's possible.

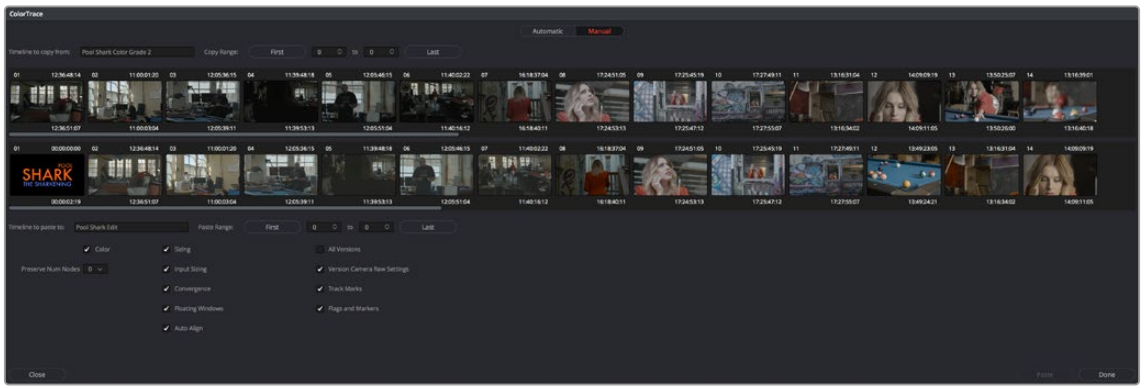
4 When you're finished, click Copy Grades & Exit.

Using ColorTrace in Manual Mode

Manual mode is ideal for situations where you want to copy grades between programs with clips that have no timecode or reel name correspondence at all. The Manual ColorTrace interface is designed to let you move through two different timelines, either a clip at a time, or in matching multiples of clips, copying grades from the Source timeline to the Target timeline.

For example, if you're trying to copy grades from a timeline that was conformed from individual media files, to another timeline that was conformed from a flattened master media file, you can use the ColorTrace Manual mode to accomplish this.

The manual interface consists of two sets of controls that correspond to the Source timeline (labeled "Timeline to copy from"), and the Target timeline (labeled "Timeline to paste to"). The general idea is that you move through both sets of timelines one clip at a time, or in matching multiples of clips at a time, and copy grades from the "Copy from" timeline to the "Paste to" timeline.



ColorTrace Manual window

Manual mode has the following controls:

- **Source timeline:** Shows all clips in the Source timeline you selected; the clips you're copying grades from. Click any one clip thumbnail to select it, or click a thumbnail, and then Shift-click another thumbnail to select a contiguous range of clips. You cannot select a noncontiguous range of clips.
- **Copy Range controls:** Two fields show the range of clips in the current selection that you'll be copying from, referred to by their numeric position in the Source timeline. You can change the range numerically by either entering new numbers in the fields, or by using the up/down arrow buttons to alter the value by one. The First button automatically adds all clips from the first one in the Timeline into the current selection. The Last button automatically adds every clip going to the last one in the Timeline to the current selection.
- **Target timeline:** Shows all clips in the Target timeline you selected; the clips you're pasting grades to. Selecting clips works identically as with the Source timeline.
- **Paste Range controls:** Two fields show the range of clips in the current selection that you'll be pasting to, referred to by their numeric position in the Source timeline. All controls work identically to the Copy Range controls.
- **Attributes and options checkboxes:** Turn off the checkboxes of any clip characteristics that you don't want to copy as part of the ColorTrace operation. A more complete description of these options appears in the section on the Automatic ColorTrace mode.
- **Paste button:** Once you've selected one or more source clips and a matching number of target clips, clicking Paste copies the grades, PTZR settings, and marks (depending on the corresponding checkboxes).
- **Undo Last:** Lets you undo the most recent paste action.
- **Undo All:** Lets you undo all paste actions in Manual mode.
- **Done:** Finishes the operation and closes the ColorTrace window.

If you're cherry picking individual grades from one timeline to paste into shots in another, you can copy grades one at a time.

To copy one source grade to one target clip:

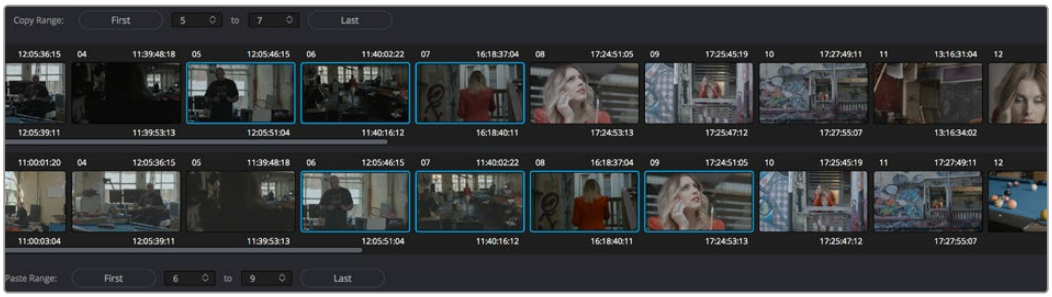
- Click a thumbnail in the Source timeline (on top) to copy from, then click a thumbnail in the Target timeline (on the bottom), and click Paste.

You can also simultaneously copy the grades of entire scenes of clips from one timeline to another. For example, if you're copying grades from an originally graded timeline to a re-edited version of the same program, you can copy every grade from a 10-clip scene in the Source timeline to the same 10 clips in the Target timeline which have been pushed back later in the Timeline.

To copy a group of source grades to a group of target clips:

1 Choose a continuous range of source clips by doing one of the following:
   - Click the first clip in the range, and then Shift-click the last clip in the range.
   - Enter the clip number of the first clip in the left “Copy Range” field, and then enter the clip number of the last clip in the right field.
   - Click a clip, and then click First to select every clip from that one to the first clip in the Timeline.
   - Click a clip, and then click Last to select every clip from that one to the last clip in the Timeline.
2 Choose a continuous range of Target clips by using the same procedures as in the previous step, but using the “Paste Range” controls.

> **IMPORTANT:** You must select the same number of target clips as you did source clips for the Paste button to become enabled.



Group copy and paste of grades

3 When you’ve made your selections, click Paste.

   The grade settings from the source clips are pasted to the destination clips, in order. In other words, if you copy from clips 5 through 9 to clips 11 through 15, then grade 5 is copied to shot 11, grade 6 is copied to shot 12, grade 7 is copied to shot 13, and so on.

Importing CDL Data Using ColorTrace

The ColorTrace CDL command lets you import ASC CDL file formats from other applications into DaVinci Resolve. DaVinci Resolve also has the ability to read DRX filenames from CDL files, allowing a CDL to load exported DaVinci Resolve grades.

There are three supported file formats:

- **CMX EDL:** An EDL with comments referring to CCC/CDL XML files, or even Slope, Offset, and Power (SOP) data within the comment area.
- **CCC and CDL XML:** A file format that contains various color correction looks, and even references.

To import CDL data into DaVinci Resolve:

1 If you’re importing CCC/CDL XML correction looks:
   - Open the Gallery page, right-click anywhere within the Stills tab, and choose Import from the contextual menu.
   - When the Import Stills dialog appears, open the CDL/CCC files. When these are finished importing into the Gallery, an ASC logo will appear along with them.
2 Open the Edit page and select the Timeline you want to use ColorTrace with in the Timeline list.

3. Right-click anywhere within the Timeline, and choose ColorTrace from CDL.
4. Select an EDL using the Select EDL dialog, and click Open.
5. Select its corresponding CDL and CCC files using the Select CDL Files dialog. If there are no CDL or CCC files (which is the case if there are inline SOP comments within the EDL), you should click Cancel.
6. Using the ColorTrace With CDL window, copy the source grades from the CMX EDL/CCC & CDL XML files to the Target timeline.

   At this point, the ColorTrace window works identically as previously described.

For formatting reference, here are some examples of CMX, CCC, and CDL files.

Example CMX EDL File

```
TITLE: Final EDL FCM: NON-DROP FRAME 010 001 V C 01:19:28:16 01:19:28:16
01:00:41:18 01:00:42:18 *ASC_CC_XML test_cc.102 011 001 V C 00:00:00:00
01:19:28:16 01:00:42:18 01:00:43:18 *ASC_SOP (0.9 1.2 0.5)(0.4 -0.5 0.6)(1.0
0.8 1.5)
```

Example CCC File

```

<MediaRef ref=<94>/some/Project/frame%250900-0954%5B.dpx<94>/>
<ColorCorrection id=”cc03340”>

<SOPNode> <Description>change +1 red, contrast boost</Description>
<Slope>1.2 1.3 1.4</Slope> <Offset>0.3 0.0 0.0</Offset> <Power>1.0 1.0
1.0</Power>

</SOPNode> </ColorCorrection>
</ColorDecision> </ColorDecisionList>
```

Using CDL Adjustments

Once you've imported a CDL (Color Decision List), then the CDL adjustment for each clip is made available to you via a contextual menu command in the Thumbnail timeline of the Color page.

Calculating CDL Functions

To turn the SOP values into a primary correction, the following math is used by DaVinci Resolve:

```
Output = (Input * Slope + Offset)Power
```

Output refers to the final grade. Input is the value of each pixel within each color channel (on a scale from 0–1). The detent value for Slope is 1. The detent value for Offset is 0. The detent value for Power is 1.

Chapter 148

Using LUTs

Lookup Tables, also known as LUTs, are one of the most ubiquitous means of creating, exchanging, and applying image processing operations there is for purposes of color management, display calibration, look management, and general-purpose processing of image color and contrast. DaVinci Resolve has robust support for LUTs throughout its image processing pipeline.

What is a LUT?

LUTs are simply files, similar to plugins but far more focused and with no user interface, that specify image processing operations. These operations are accomplished in a variety of ways. The traditional approach is to use a 1D table or 3D "cube" of pre-calculated values to perform an image color transform. However, newer LUT formats including CLF and DCTL let you use mathematical scripts to process an image.

Whatever type of LUT you use, these files can be loaded into DaVinci Resolve and applied at different points of the image processing pipeline to apply image processing operations for different purposes. There are several well-known uses of LUTs, but the important thing you should take away is that LUTs are simply color transform operations that can be used for many things, and there's no single use of a LUT that's more or less important than any other.

Here are some frequent uses for LUTs:

- While optionally superseded by Resolve Color Management (RCM), lookup tables (LUTs) have been frequently used to create a starting point adjustment for media acquired with some logarithmic encoding. DPX log film scans, digital media using the ARRI ALEXA's Log-C encoding, Sony's S-Log exposure setting, or RED R3D media that is debayered using the REDFilmLog setting are all examples of media using a logarithmic exposure curve, designed to protect as much detail in the highlights and shadows of a digitally encoded image as possible. While log-encoded media retains a lot of image data, the picture is initially flat and unsuitable for use without grading. The exposure and color must be adjusted to "normalize" the media, making it look closer to the way it's supposed to, in order to start grading. While you can do this manually, it's usually faster to use a LUT that's tailored to your type of media and the exposures you're using. Alternately, you can also use Resolve Color Management to accomplish this.
- LUTs are commonly used in onset workflows where dailies for different scenes are managed with corresponding LUTs. These LUTs were used to monitor the media as it was being recorded to define a baseline reference for how each scene is meant to look, at least so far as field monitoring is concerned. In more advanced workflows, LUTs are used as a baseline look, defined prior to the shoot and used during the shoot, that then defines the creative starting point for different scenes once grading begins after the shoot.
- LUTs are frequently used as a stylistic component of a grade, or "look" that gives users a quick start when desiring some manner of creative adjustment. Over the years, companies and individuals have created an ecosystem of such looks that are disseminated and sold in various LUT formats supported by DaVinci Resolve.

In all of these instances, LUTs are simply image processing adjustments that are applied to affect the color and contrast of a clip, in much the same way as you'd make adjustments using any of the contrast or color controls in the Color page.

Supported LUT Formats

DaVinci Resolve uses both 1D and 3D LUTs, and supports LUTs in a variety of formats.

- **.cube:** DaVinci Resolve uses both 1D and 3D LUTs in the .cube format. 3D LUTs can be exported as 17x17x17, 33x33x33, or 65x65x65 cubes with 32-bit floating point processing. DaVinci Resolve can also read and use Shaper LUTs in the .cube format, but these must also be created outside of DaVinci Resolve. You should note that while 17-point LUTs are not recommended to use for grading, they are useful when exporting LUTs for on-set monitoring, to accommodate different display, calibration, and signal conversion devices.
- **Panasonic VLUT format:** DaVinci Resolve can both read and generate this LUT format, designed for use in the Panasonic VariCam camera ecosystem.
- **Video Range LUTs:** Beginning with DaVinci Resolve 17, support was added for importing LUTs that include additional metadata specifying them as processing image data in Video Range, rather than Full Range. More information about how to format LUTs as Video Range is included in the Developer Documentation available from the Help menu. Being able to specify whether a LUT is meant to be Video or Full Range allows LUT processing to automatically accommodate DaVinci Resolve's data range setting pipeline for clip attributes, project settings, and output settings.
- **CLF (common LUT format):** CLFs use an XML format that is capable of encompassing a limited number of mathematical transforms in addition to traditional lookup-tables to do image processing. Promoted by the academy as the ideal LUT format for use with ACES, LMTs for ACES are recommended to be in the CLF format due to its increased precision and flexibility.
- **DCTL:** DCTL files are actually color transformation scripts that DaVinci Resolve sees and applies just like any other LUT. Unlike other LUTs, which are 1D or 3D lookup tables of values that approximate image transformations using interpolation, DCTL files are actually comprised of computer code that directly transforms images using combinations of math functions that you devise. Additionally, DCTL files run natively on the GPU of your workstation, so they can be fast.

For more information on DCTL, *see Chapter 196, "Creating DCTL LUTs."*

What's the Difference Between a LUT and a Shaper LUT?

DaVinci Resolve is capable of importing and using LUTs within its 32-bit floating point image processing pipeline. The .cube format can be used as either a simple 33x33x33 3D LUT, or as a shaper LUT, which is actually a method of using two LUTs, a 1D LUT and a 3D LUT together, that addresses signal processing issues that 3D LUTs alone can't handle.

For processor efficiency, 3D LUTs are designed with reasonable lower and upper limits for the data they will handle. It's well known that when a 3D LUT is fed values that are outside of the range that LUT is designed to handle, the out-of-range data will be clipped. Since many LUTs are designed with digital cinema workflows in mind, the practical result is that feeding a video signal with super-white in it to a 3D LUT that's designed for full-range data (0–1) will clip the super-white part of the signal.

Shaper LUTs handle this issue by first using a 1D LUT to process video signals with out-of-range data, fitting the signal into a range that the 3D LUT won't clamp. The output of the 3D LUT includes the reverse transformation, to effectively zero out the 1D LUTs transform, while retaining whatever processing the 3D LUT was meant to apply.

Shaper LUTs are also useful for dealing with extremely large data sets, such as OpenEXR files that can theoretically handle an image data range of –infinity to +infinity. Using a Shaper LUT, you can remap the incoming data to fit more precision in the 0–1 range, leaving less important data outside the range.

LUTs and ACES

The academy that promotes the correct use of ACES strongly recommends that LUTs be processed in the ACES color space. For this reason, two project settings let you choose how this will be done:

- **ACEScc AP1 Timeline Space:** This setting works for either the ACEScc or ACEScct Color Science settings depending on what you've selected in the Color Science pop-up at the top of the Color Management panel in the Project Settings. This setting lets you use LUTs that were created for ACES workflows that are similar to (but not the same as) LUTs you would create and use in a traditional log-encoded workflow. LUTs designed for working with this setting should have a range of –0.358 to 1.468 so that grading operations that clip an image from 0 to 1 won't destroy the look being applied.

  The "ACEScc AP1 Timeline Space" setting is also good for workflows where you want to use conventional LUTs that were designed for Rec. 709 workflows using the ResolveFX "ACES Transform" plugin, which over a series of three nodes lets you transform the image from ACES to 709, apply a Rec. 709-designed LUT, and then convert the image from 709 back to ACES.

- **ACES AP0 Linear:** This setting requires you to apply an LMT LUT that has been specifically created for ACES image data. Only use this setting if you're using CLFs that are designed for ACES using a range of –65504 to 65504, as specified by SMPTE 2065.

Adding Lookup Tables of Your Own

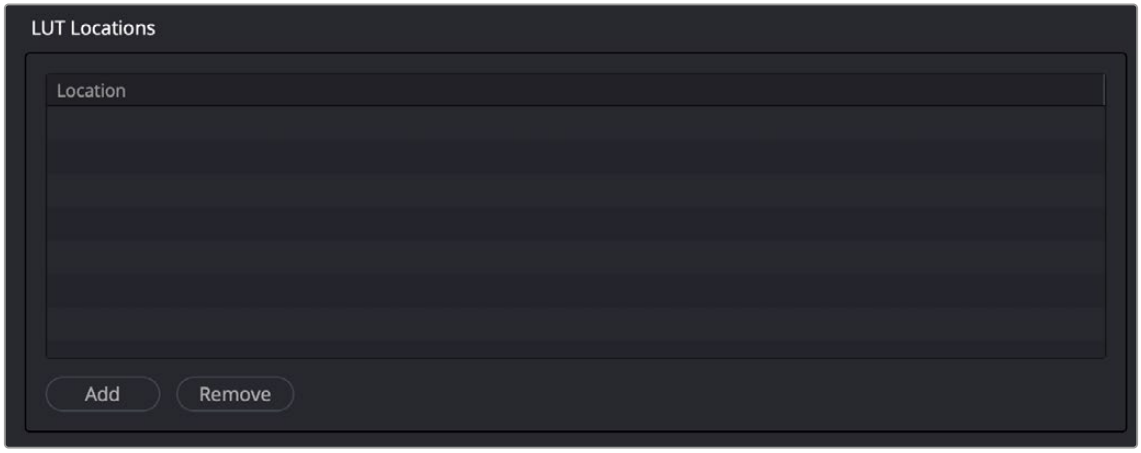
The menus in the Color Management panel of the Project settings include a series of factory preset LUTs that were installed with DaVinci Resolve, along with any LUTs that have been generated by DaVinci Resolve, or that you've imported into the proper directory for your operating system for your own use.

By default, LUTs are saved to the following locations:

- **On OS X:** Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
- **On Windows:** C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
- **On Linux:** /home/resolve/LUT

Custom LUT Paths

A list in the General panel of the DaVinci Resolve System Preferences lets you add multiple file paths for loading LUTs that you want to use in DaVinci Resolve. This works for network volumes for facilities where multiple workstations are accessing a central collection of LUTs to be shared among multiple artists. Clicking the Add button lets you add a file path to this table from a dialog. Selecting a location in this list and clicking Remove removes that location.



A list in the General panel of the System Preferences lets you add multiple locations where LUTs you want to use from within DaVinci Resolve are located.

LUT Paths for the macOS App Store Version of DaVinci Resolve

If you downloaded the non-studio version of DaVinci Resolve from the Apple App Store, LUTs are saved in a different location in order for DaVinci Resolve to remain totally self-contained. In this case, you can click the Open LUT Folder button in the Lookup Tables panel of the Project Settings, to open up a Finder window at the location these LUTs are stored. You can use this window to copy LUTs that you want DaVinci Resolve to have access to, or delete LUTs that you no longer need.

If you add a LUT to one of these directories after DaVinci Resolve has been opened, you can click the Update Lists button to refresh the contents of the pop-up menus.

LUT Controls in the Project Settings

While there's an entire group of LUT controls in the Color Management panel of the Project Settings, those are designed to apply LUTs, at different parts of the image processing pipeline, to the entire Timeline. This is useful when you want to apply a single color and contrast transformation to the entire program at once, but less so if you want to apply different LUTs on a per clip basis.

> For more information on using the Lookup Table settings, *see Chapter 4, "System and User Preferences."*

Applying LUTs to Source Clips

Another way of applying a LUT to a clip is to apply it directly to the source clip, which you can do to any clip in the Media Pool, or in the Thumbnail Timeline of the Color page. This can be convenient, but keep in mind that source clip LUTs cannot be copied from one timeline to another using ColorTrace, so using source clip LUTs limits your potential workflows. For most workflows, it's better to apply LUTs directly in the Node Editor so they live in each clip's grade.

To apply a LUT to one or more selected clips in the Media Pool:

- Right-click one of the selected clips, and choose a LUT from the 1D LUT or 3D LUT submenus.

To apply a LUT to one or more selected clips in the Thumbnail Timeline of the Color page:

- Right-click one of the selected thumbnails, and choose a LUT from the 1D LUT or 3D LUT submenus.

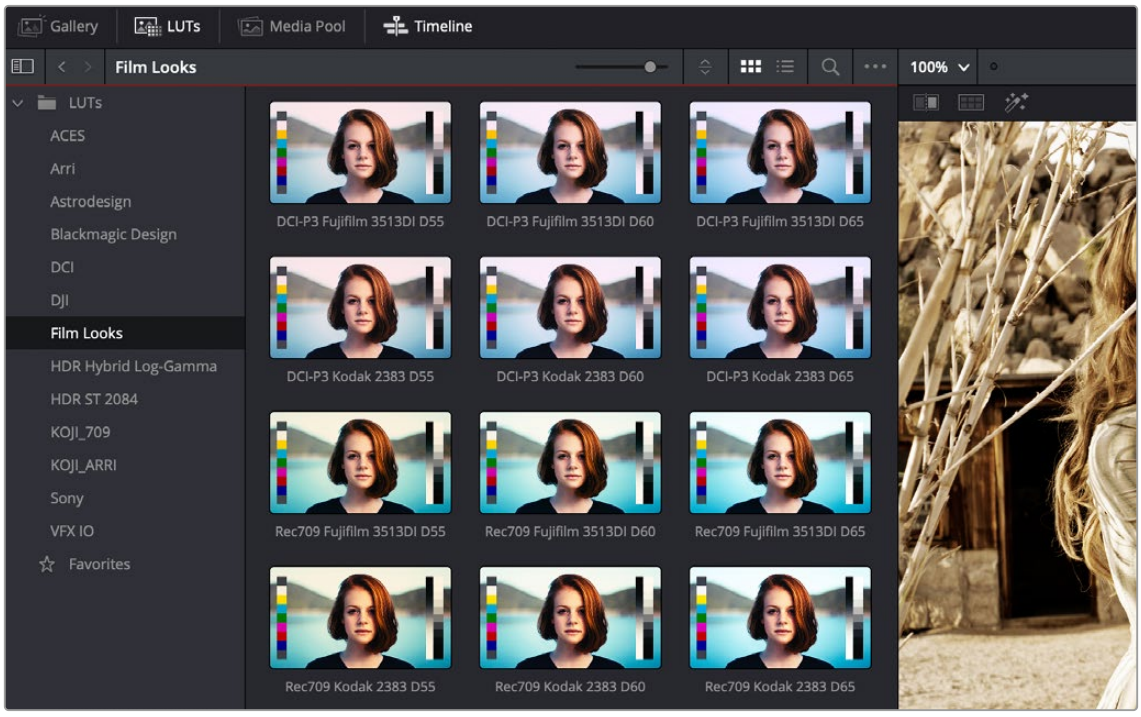
TIP: If you're wanting to apply an image transformation to normalize log-encoded source clips, you may also consider using Resolve Color Management (RCM). Depending on your source media, it may be an easier and more automated process.

For more information, *see Chapter 9, "Data Levels, Color Management, and ACES."*

Using the Color Page LUT Browser

The LUT Browser on the Color page provides a centralized area for browsing and previewing all of the LUTs installed on your workstation. All LUTs appear in the sidebar, by category.

By default, all LUTs appear with a test thumbnail that give a preview of that LUT's effect, but you can also get a live preview of how the current clip looks with that LUT by hover scrubbing with the pointer over a particular LUT's thumbnail (this is described in more detail below).



The LUT Browser

To open the LUT Browser:

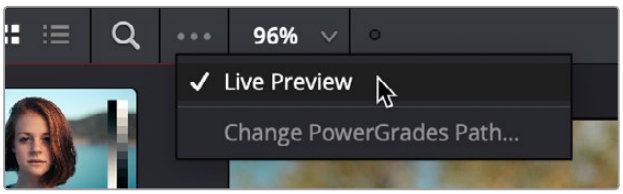
- Click the LUT Browser button in the UI Toolbar at the top of the Color page.

Methods of working with the LUT Browser:

- **To see the LUTs in any category:** Click on a LUT category to select it in the sidebar, and its LUTs will appear in the browser area.
- **To make a LUT a favorite:** Hover the mouse over a LUT and click the star badge that appears at the upper right-hand corner, or right-click any LUT and choose Add to Favorites. That LUT will then appear when you select the Favorites category in the Node Editor contextual menu for nodes.
- **To search or filter for specific LUTs:** Open a bin that has the LUT you're looking for, then click the magnifying glass icon to open the search field, and type text that will identify the LUTs you're looking for.
- **To see LUTs in Column or Thumbnail view:** Click the Column or Thumbnail buttons at the top right of the LUT Browser to choose how to view LUTs in the browser area.
- **To sort LUTs in Thumbnail view:** Click the Thumbnail Sort pop-up menu and choose which criteria you want to sort LUTs by. The options are filename, type, relative path, file path, usage, date modified. There are also options for ascending and descending sort modes.
- **To sort LUTs in Column view:** Click the column header to sort by that column. Click a header repeatedly to toggle between ascending and descending modes.
- **To update the thumbnail of a LUT with an image from a clip:** Choose a clip and frame that you want to use as the new thumbnail for a particular LUT, then right-click that LUT and choose Update Thumbnail With Timeline Frame.
- **To reset the thumbnail of a LUT to use the standard thumbnail:** Right-click a LUT and choose Reset Thumbnail to go back to using the standard test image.
- **To refresh a LUT category with new LUTs that may have been installed:** Select a LUT category, then right-click anywhere within the browser area and choose Refresh to refresh the contents of that category from disk.

Enabling and Disabling the LUT Viewer live preview:

1 Open the LUT Viewer's option menu and choose Live Preview.



The Live Preview option for the LUT browser lets you hover over a LUT to preview it on the current clip in the Viewer

2 Click a node in the Node Editor you want to preview applying a LUT to. The live preview will display how the current clip will appear with the LUT you select applied to the currently selected node of the current grade, which will affect the result.

3 Move the pointer over the LUT you want to preview.

The Viewer image updates to show how that clip would look with that LUT applied to the currently selected node.

To apply a LUT from the LUT Browser to a specific node, do one of the following:

- Right-click a LUT and choose Apply LUT to current node.
- Drag a LUT from the LUT Browser and drop it onto the node you want to apply a LUT to. If you drag a LUT onto a node that already has a LUT, the previous LUT will be overwritten by the new one.

Applying a LUT Within a Node

DaVinci Resolve lets you apply LUTs within a grade by connecting a LUT to a particular node in the Node Editor. This gives you the greatest amount of control over where the LUT is applied in your image processing pipeline, and it also gives you the opportunity to apply image adjustments prior to the LUT, and after the LUT, as you require.

To apply a LUT within a node, do one of the following:

- Right-click any node, and choose a LUT from the 1D Input LUT, 1D Output LUT, 3D LUT, DCTL, or CLF (common LUT format) submenus of the LUT submenu. The LUT submenus list whichever LUTs have been installed on your workstation.

  For more information on installing LUTs, *see Chapter 4, "System and User Preferences."*

- Right-click any node, and choose a LUT from the LUT > Favorites submenu.
- Use the LUT Browser to find a LUT you want to use, and then drag and drop that LUT onto the node you want to apply it to

  TIP: If you hold down the Option key while scrolling through the submenu of LUTs in a Corrector node's contextual menu, you'll get a live update in the Viewer of how each LUT affects the image.

To reveal a selected node's LUT:

For any node in the Node Editor with a LUT applied to it, you can right-click that node and choose Reveal Selected LUT to automatically open the LUT viewer and select that LUT.

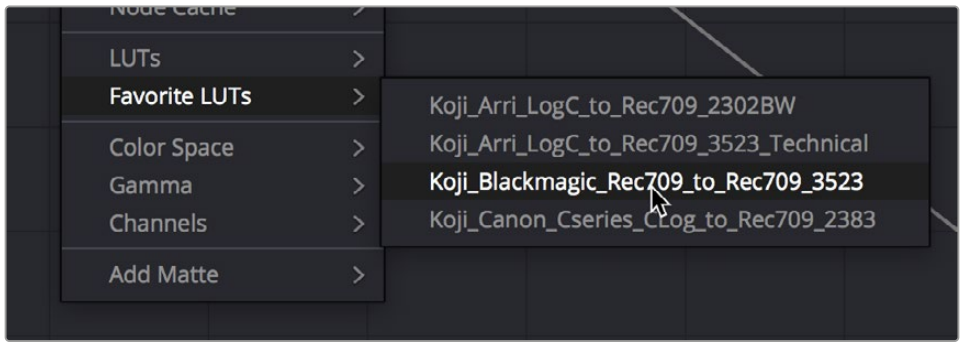
LUTs Are the Last Operation Within a Node

Each node in the Node Editor is capable of performing multiple operations, and these operations occur in a specific order. LUTs that you add to a node impose their transformation as the last operation within that node, after all other Color page adjustments applied by that node.

Practically, this means that you can use a node's Color and Contrast controls to trim the image data that will be fed into a LUT applied to that same node. For example, if a LUT's contrast adjustment clips the highlights of the image too much, you can use that node's Contrast controls to lower the highlights of the image prior to the LUT, restoring detail to the image.

Favorite LUTs Submenu in Node Editor

When you “star” a LUT as a favorite in the LUT Browser, those favorite LUTs appear in a submenu of the contextual menu that appears when you right-click on a node in the Node Editor. This makes it easy to create a short list of your go-to LUTs for various situations, for rapid application right in the Node Editor.



A Favorite LUTs submenu in the Node Editor contextual menu gives you a short list

Missing LUTs

Clips with missing LUTs show an overlay at the bottom right of the screen indicating the name of the LUT if a single LUT is missing, or an indicator that multiple LUTs are missing. This allows for quick previews of missing LUTs without interruption. Multiple missing LUTs can be seen and managed from the Missing LUTs tab in the LUT Browser, which only appears if you have one or more LUTs missing.

Exporting LUTs

If you find it necessary to exchange image adjustments with other grading applications, compositing applications, or NLEs, often the easiest inter-application solution is to export a LUT. This can be done whether your grade consists of one node or several nodes, so long as they contain only Primaries palette adjustments, Custom Curves palette adjustments, and compatible ResolveFX plugins that include Color Space Transform, ACES Transform, and Gamut Mapping. All nodes with compatible functions will be mathematically combined and translated into a LUT.

Keep in mind that any nodes that use Qualifiers, Windows, incompatible filtering operations (such as sharpening or blurring), or incompatible Resolve FX or Open FX will be completely ignored, as will all other correction operations made within these nodes.

To export a LUT:

1. Right-click a clip thumbnail in the Timeline of the Color page, and choose an option from the Generate LUT submenu:
   - **Generate 3D LUT (17 Point Cube):** A DaVinci-developed LUT format
   - **Generate 3D LUT (33 Point Cube):** A DaVinci-developed LUT format
   - **Generate 3D LUT (65 Point Cube):** A DaVinci-developed LUT format
   - **Generate 3D LUT (Panasonic VLUT):** A LUT format associated with Panasonic VariCam cameras

2 Choose a location for the resulting LUT file in the file dialog. The default file path depends on your operating system; saving it here will make it available to DaVinci Resolve for future use.

- **On OS X:** Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
- **On Windows:** C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
- **On Linux:** /home/resolve/LUT

If you like, you can create a new folder in which to save your custom LUTs.

3 Enter a name into the Save As field, and click Save. A LUT file is saved.

Once created, you can use an exported LUT from within DaVinci Resolve, applying it to a clip or node directly, or applying it to the entire project using the settings found in the Color Management panel of the Project Settings. You can also copy the LUT to a memory stick to give to someone for monitoring or previewing in an onset workflow, or to someone using another grading application that can read this LUT format.

Resolve FX

Resolve FX are the built-in plugins that come with DaVinci Resolve. These plugins span the gamut from blurs and complex color adjustments to stylized image treatments and lighting effects to sharpen and repair operations that are too complex to accomplish using the palette controls of the Color page.

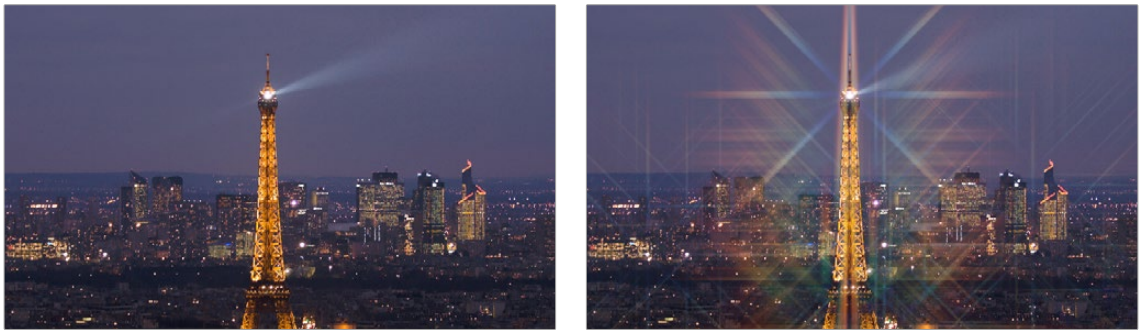
An image before/after using the Abstraction Resolve FX filter

Most Resolve FX plugins have been optimized for real-time playback, making it possible to apply complex effects such as Lens Flares, Light Rays, Film Grain, or Warping, and make adjustments while getting immediate, high-quality feedback, and enabling you to play each variation of your effect as you work without the need to wait for rendering or caching to happen first. Of course, if you're working with extremely high-resolution or raw source media, if your workstation is particularly old, or if you're applying many Resolve FX all at once, your performance may slow, necessitating the use of either the Smart Cache or User Cache.

Open FX

Open FX (OFX) is an open plugin standard intended to enable easier development of cross-platform visual effects plugins for a variety of applications. Popular plugin packages include BorisFX Sapphire and Continuum Complete, Red Giant Universe, and NewBlue TotalFX, all of which are ubiquitous tools for feature and broadcast work. The available Open FX plugin packages are also growing every year as this format becomes more widely adopted among developers.

With Open FX support, you can use plugins to do many stylized operations that would be difficult or impossible to do using the other tools in DaVinci Resolve. Everything from lens flares, optical blurs and prism effects, lens warp correction, film and video grain and damage effects, dead-pixel corrections, and more can be accomplished with the right plugin collection.



One of the many Sapphire OFX plugins from GenArts

The installation and licensing of Open FX plugins is handled by a vendor's own installer. Once installed, Open FX plugins appear within the Library of the Open FX panel, which can be opened by clicking the FX button at the top right of the Color page or Edit page Interface toolbar.

Where are OFX Installed?

According to the standard governing how OFX work, all OFX plugins on a particular workstation are installed into a standardized location to foster plugin compatibility with multiple applications. These locations are:

- **On macOS:** /Library/OFX/Plugins
- **On Windows:** C:/Program Files/Common Files/OFX/Plugins
- **On Linux:** /usr/OFX/Plugins

Open FX Plugins Can Be Processor Intensive

Because they create such a wide variety of effects, some third-party Open FX plugins can be extremely processor intensive, all the more if you add multiple plugins to a single grade. If you find your playback performance dropping because of a particularly expensive effects operation, you can use the Smart Cache to automatically cache nodes and clips that have Open FX plugins applied to them. Once fully cached, you can play these clips back in real time, at least until you change that clip's grade again.

> For more information on caching and on improving performance in DaVinci Resolve overall, *see Chapter 8, "Improving Performance, Proxies, and the Render Cache."*

Browsing the Effects Library

All of these built-in plugins appear within categories at the top of the Effects Library.

Click the Effects button to open the Effects Library

When you click the Effects button, the Effects panel opens out of the right side of the Node Editor to show the Library, resizing the Viewer, Gallery, and Node Editor to make room. The Effects Library is organized hierarchically. Each vendor's plugins appear under a header with the name of that plugin collection, and possibly organized into categories, separated by headers with Open or Close arrows that appear to the right of the category name, which let you show or hide the contents so that you can make the hierarchy as compact or spread out as you like.

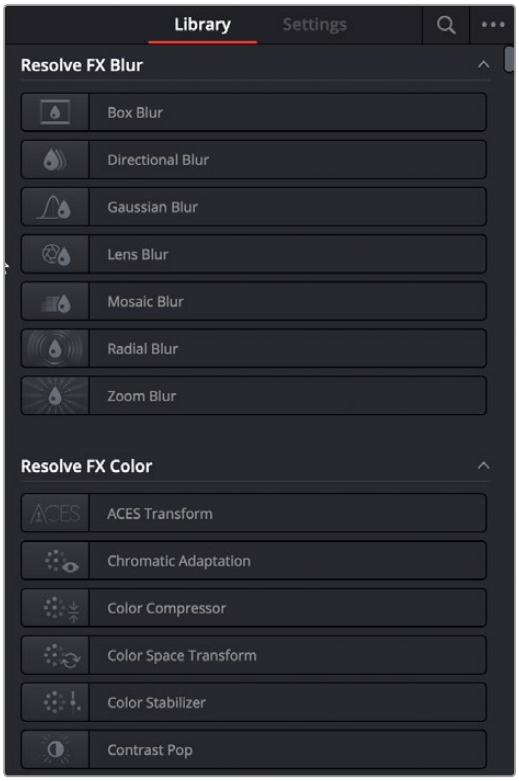
To open and close Effects categories, do one of the following:

- Move the pointer over the header you want to open or close, and click the Close or Open arrow to the right of the category name.
- To open or close all headers at once, Option-click the Open or Close arrow.

Since many Open FX plugin collections are quite large, an optional Search field can be opened at the top of the Library that lets you quickly find plugins by name or partial name.

To search for an Effects filter by name:

1. Click the magnifying glass button at the upper right-hand corner of the Effects panel.
2. Type your search string into the Search field that appears. A few letters should be enough to isolate only those plugins that have that character string within their name.



The Library in the Effects panel showing available effects

Stars indicate a flagged favorite effect

Effects Library Favorites

You can click on the far right of any Resolve FX or OFX filter to flag it with a star as a favorite filter. When you do so, choosing Favorites from the Effects Library option menu filters out all clips that are not favorites, letting you see only effects you most commonly use. To “de-favorite” any effect, click its star to turn it off.

Using Resolve FX and Open FX in the Color Page

This section provides an overview of procedures that describe how you can work with Open FX plugins within the Color page.

Methods of working with Open FX:

- **To add an Open FX plugin to a node:** Drag a plugin from the Open FX Library onto a node. If you drag a plugin onto a node that already has a plugin, the previous plugin will be overwritten.
- **To remove an Open FX plugin from a node:** There are two ways to delete an Open FX plugin from a node.

Right-click a node showing the FX badge, and choose Remove OFX Plugin from the contextual menu.

Click on the trashcan icon to the right of the name of the effect in the Effects Inspector.

- **To edit the parameters of an Open FX plugin:** Select any node with an FX badge, and open the Open FX Panel to show the Settings list. You can switch to the Library by clicking the Library button.
- **To sample a color parameter within an Open FX plugin:** Some OFX plugins have a color swatch parameter, which exposes an eyedropper button in the Settings. Clicking the eyedropper turns the pointer into an eyedropper you can use to sample the contents of the Viewer.
- **To use Open FX onscreen controls in the Viewer:** Select any node with an FX badge, and the onscreen controls, if there are any, should appear in the Viewer. If not, make sure the Viewer mode drop-down is set to FX.

Applying Resolve FX and Open FX Plugins

Once you've found an Open FX plugin you want to use in the Library, there are two ways of applying it within the Node Editor of the Color page. Which method you use depends on how you want to use that plugin.

Adding a Plugin to an Existing Corrector Node

If you want to combine an Open FX plugin with a grade within a single node, simply drag and drop it onto a new corrector node to apply that plugin's effect to that node. Nodes with an Open FX plugin applied have an FX badge in the bottom left-hand corner.

A node with an Open FX plugin mapplied

You can only apply one Open FX plugin to a node at a time, but by using multiple nodes you can add as many Open FX plugins to your grade as you need.

When added to a corrector node, Open FX are applied after Motion Blur and Noise Reduction, but before anything else. This means you can use Motion Blur and Noise Reduction to pre-process the image before it's handed off to the Open FX plugin. This also means that all other adjustments you make within that node are applied to the Open FX plugin's output.

However, the principal advantage of adding plugins to corrector nodes is that you can use secondary operations such as a window, a qualifier, or a key to limit that plugin's effect, much as you would limit any other kind of adjustment you'd make with a corrector node.

Adding a Plugin as a New Corrector Node

If you want to add an Open FX plugin to your grade as a stand-alone effect, you can simply drag any plugin from the Open FX Library into the Node Editor or onto a connection line of your grade, and a new Corrector Node with the Open FX plugin applied will be created.

This new node will now include all the additional inputs and Alpha connectors needed to use the effect. So now that color correction nodes can be used for everything, there is no need to make separate FX nodes anymore. This should help simplify node trees and involve much less manual management of connections between nodes.

Adding a Plugin as a Stand-Alone FX Node (Legacy)

As part of an overhaul of the Resolve FX system to make it more intuitive and easier to use, dragging an effect from the Effects Library into the Node Editor will now create that effect using a standard corrector node and not an FX Node.

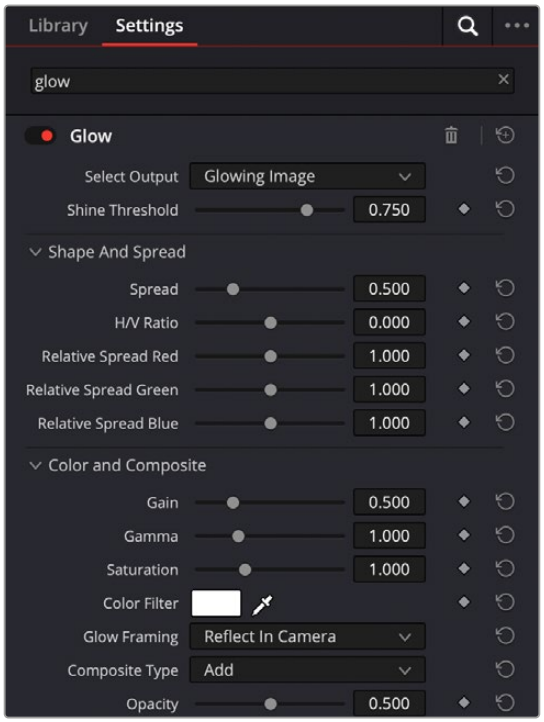
As of DaVinci Resolve 18.5, FX nodes have been depreciated. There is no need to make an FX node anymore as all of the previous functionality found in FX nodes have been rolled into the standard corrector node instead.

However for legacy projects, or if you still prefer to work in the old way, you can still force an FX node by option-dragging the effect from the Effects Library into the Node Editor instead of dragging it.

Resolve FX and Open FX Settings

When you select a node with a Resolve FX or Open FX plugin applied to it, the Open FX panel switches to the Settings, which show you every single parameter associated with that plugin, ready for customization.

Adjust any of the standard controls to manipulate that plugin's effect on the image.



The parameters of the Glow Resolve FX

Editing Effects Using the Full Screen Viewer

Because the Open FX panel can often be too short to present the full controls of more complicated filters, it remains visible when you switch to the Full Screen Viewer mode in the Color page. Jump into this mode by choosing Workspace > Viewer Mode > Full Screen Viewer (Shift-F).

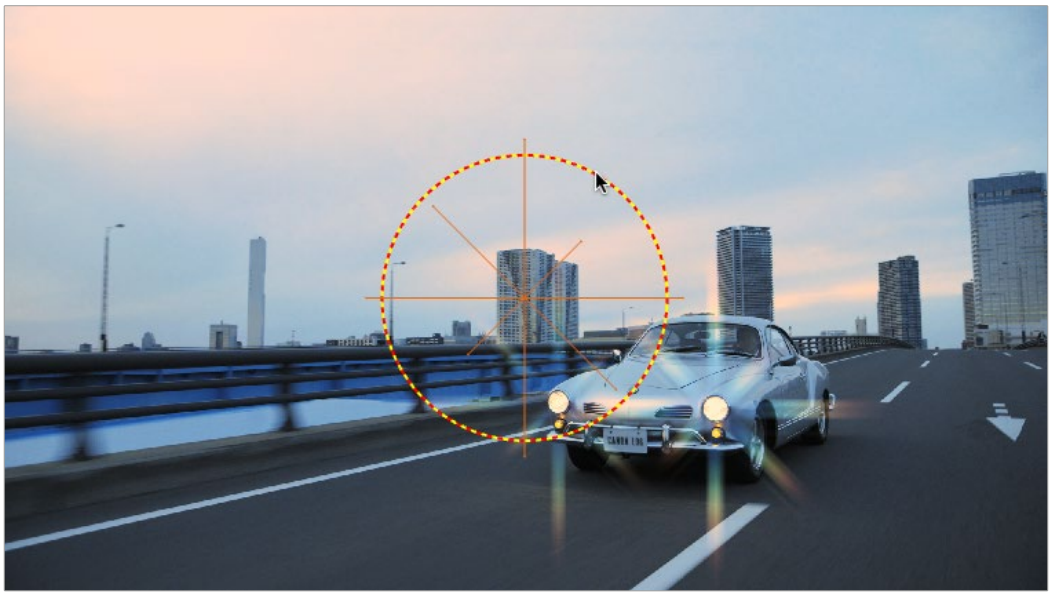
This control layout makes it considerably easier to do detailed work while viewing a larger image and having all of your effects visible in a taller panel off to the side.

The Full Screen Viewer mode of the Color page lets you keep the Settings panel open as you work

TIP: You can also open and close the Node Editor while in Full Screen Viewer mode, if you need to switch nodes while doing effects work.

Resolve FX and Open FX Onscreen Controls

In the Edit page, Fusion page, and Color page, Resolve FX and Open FX display on-screen controls that you can use to visually edit an effect. In the Edit and Color pages, selecting an Open FX plugin node or a plugin in the Inspector that has onscreen controls automatically changes the Viewer's mode to Open FX Overlay mode, with the available controls ready to use. Different plugins expose different custom controls, letting you control the effect or manipulate the image, depending on that plugin's function.



Adjusting the onscreen controls exposed by the GenArts Sapphire Glint Rainbow plugin

If for whatever reason you switch the Viewer to another onscreen control mode (for example, showing the Window or Image Wipe controls), you can always switch back to the Open FX controls by choosing the Open FX Overlay mode from the onscreen control drop-down menu underneath the Viewer.

TIP: You may find that as you work you want to temporarily hide or show the onscreen controls in the Viewer so you can get an uncluttered look at the image you're adjusting. You can quickly toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).

Keyframing Resolve FX and OFX in the Inspector

Resolve FX and Open FX can be keyframed in the Edit, Fusion, and Color pages. However, they can only be keyframed in the Edit and Color pages using the keyframing controls found in the Inspector (at the time of this writing). Happily, most simple keyframing tasks can be performed using three buttons that appear to the right of any parameter that's capable of being keyframed. It takes two keyframes at minimum to create an animated effect.

The three keyframe controls that appear in the Inspector, from left to right: Previous keyframe, Create/Delete keyframe, Next keyframe

Methods of keyframing parameters in the Inspector:

- **To add a keyframe:** Select a clip, open the Inspector, then move the Timeline playhead to the frame where you want to place a keyframe, and click the Keyframe button next to the parameter of the Inspector you want to animate. Once you've added at least one keyframe to a parameter, all other adjustments you make to parameters in the Inspector, or using the onscreen Transform/Crop controls in the Timeline Viewer, add new keyframes automatically if the playhead is at another frame.
- **To move the playhead to the next or previous keyframe:** Click the small left- or right-hand arrow to either side of a parameter's keyframe control, or press Right-Bracket ([ ) or Left-Bracket ( ]), to jump the playhead to the next or previous keyframe.
- **To edit an existing keyframe of a parameter:** Move the playhead to be on top of the keyframe you want to edit, and then change that parameter, either in the Inspector, or using the onscreen controls of the Timeline Viewer.

Methods of changing keyframe interpolation in the Inspector:

- **To change a keyframe to Static:** (Color page only) Static keyframes create abrupt one-frame changes at the keyframe to which they're applied, which is good for creating sudden effects. Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose "Change to Static Keyframe." The keyframe control changes to a round button to show that keyframe is now Static.
- **To change a keyframe to Dynamic:** Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose "Change to Dynamic Keyframe." The keyframe control changes to a diamond button to show that keyframe is now Dynamic.

Methods of deleting keyframes and disabling keyframed effects:

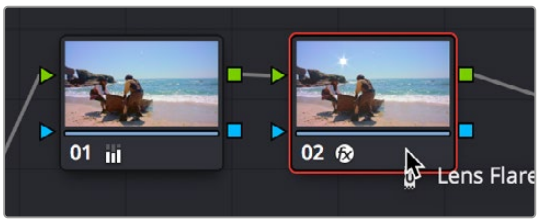
- **To delete a single keyframe:** Open the Inspector, move the Timeline playhead to a frame with a keyframe, and click the orange Keyframe button in the Inspector to delete it.
- **To delete all keyframes for one parameter:** Click the reset button to the right of a parameter's keyframe control in the Inspector.
- **To delete all keyframes in a group of parameters in the Inspector:** Click the reset button to the right of a parameter group's title bar in the Inspector.
- **To disable or enable a single parameter's keyframed effect:** In the Timeline, click the toggle control at the left of a parameter's keyframe track. A white dot means it's enabled, while no dot means it's grayed-out and disabled.
- **To disable or enable a group of parameters in the Inspector:** Click the toggle control at the left of a parameter group's title bar in the Inspector. Orange means that group is enabled. Gray is disabled.

Motion Tracking Resolve FX and Compatible OFX Plugins

When using Resolve FX in the Color page, Resolve FX that have position parameters, including Dent, Lens Flare, Light Rays (when "From a Location" is selected), Mirrors, Radial Blur, Ripples, Vortex, and Zoom Blur can all be motion tracked to follow the position of a moving subject in the frame using the the easier and more reliable IntelliTrack mode (described below) or the legacy point-based tracking in the FX mode of the Tracker palette.

To match move Resolve FX to a feature using the FX tracker:

1 Create a new node, and drag the Resolve FX filter you want to apply onto that node to apply the effect. In this example, we're adding a Lens Flare effect, that has the position parameters necessary to be match moved to follow the motion of the shot, and we're choosing the MIR-I 2.8/37 preset, which looks like a sun.

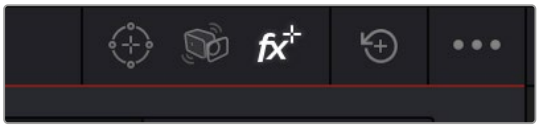


Applying a Lens Flare to the shot

2 If necessary, use the onscreen controls in the Viewer or the X Position and Y Position sliders to move the Resolve FX effect to where you want it.

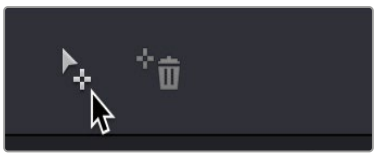
Moving the Lens Flare using the onscreen controls

3 Next, open the Tracker Palette and choose the fx icon in the upper right.



Opening the FX tracker mode of the Tracker palette

4 Click the Add Tracker Point button, at the bottom left-hand side of the Tracker palette, to add tracker crosshairs to the center of the Viewer.



Adding a point tracker

5 Drag the crosshairs to a high-contrast detail (such as a small object or corner), and click the Track Forward button. In this example, there's a rock out at sea that will make a good plane of motion for tracking a far-away sun. There is no inner or outer box to position or resize while you do this; you just need to drag the crosshairs to center on the feature you want to track.

Positioning the point tracker on a feature you want to track

6 Now, click the Track Forward button, and DaVinci Resolve will track the feature. The Resolve FX applied to that node will simultaneously move to follow the track, and when the tracking is done, you're finished.

A successful track

7 After you've finished tracking, you can freely reposition the Resolve FX to offset it from the track.

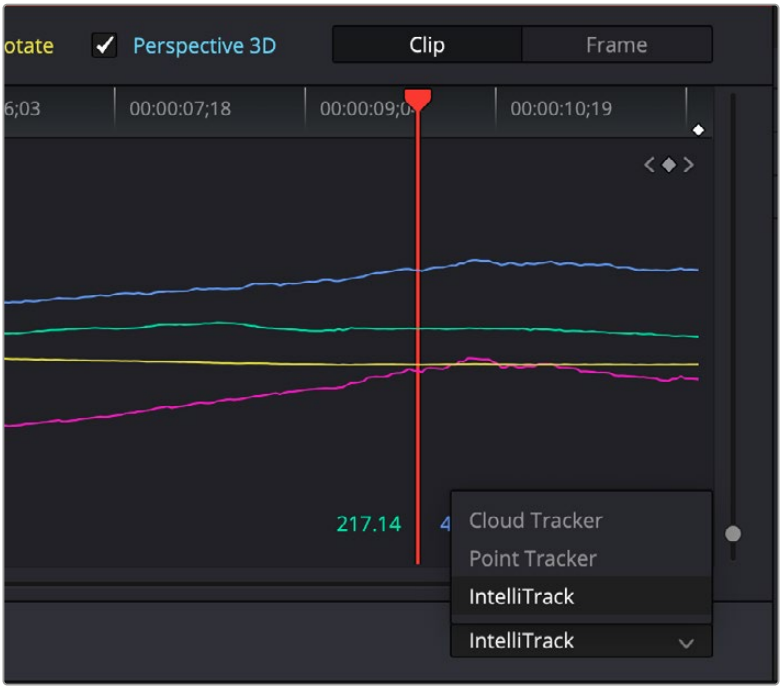
For more information about single-point tracking, refer to the "Point Tracker Workflows" section, *see Chapter 138, "Motion Tracking Windows."*

IntelliTrack AI Point Tracker (Studio Version Only)

The DaVinci Neural Engine powered IntelliTrack point tracker is available in the FX tracker in DaVinci Resolve Studio. The IntelliTrack setting can be used for tracking your Resolve FX.

IntelliTrack, like other AI tools, doesn't use predetermined rulesets or heuristics. Instead, it is trained on real world examples. This makes it less likely to fail in scenarios like tracking a subject behind brief occlusions. For most cases it will be more precise and more robust than the normal Point Tracker.

Using IntelliTrack: All the IntelliTrack analysis happens behind the scenes, and there is no additional user input required other than to choose the IntelliTrack setting, set the tracking crosshairs over high contrast areas on the same moving subject, and then press one of the tracker direction controls.



Setting the IntelliTrack mode for the Color page window tracker

Chapter 150

Sizing and Image Stabilization

DaVinci Resolve has a powerful toolset for making geometric transforms, using advanced algorithms for optical-quality sizing operations.

This section covers the nuts and bolts of resolution independence in DaVinci Resolve, and how to use the Sizing palette. This chapter also covers how to use the Stabilizer mode of the Tracker palette to subdue unwanted camera wiggle.

The Five Color Page Sizing Modes

The Sizing Palette on the Color page can be put into one of five modes, each of which accomplishes a different task.

- **Edit Sizing:** These controls mirror those found in the Inspector of the Edit page.
- **Input Sizing:** These controls let you make sizing adjustments to individual clips that affect their overall geometry (pan, tilt, zoom, and rotation). These controls are useful for doing clip-by-clip pan and scan adjustments.
- **Output Sizing:** These controls are nearly identical, except that they affect every clip in the entire timeline, all at once. Output sizing is useful for making a formatting adjustment to an entire timeline, such as changing an HD timeline to an SD timeline with simple adjustments to crop and pan the resulting framing.
- **Node Sizing:** Lets you add targeted sizing adjustments at any point within the node tree. Like Input Sizing, Node Sizing is specific to a particular clip. Unlike Input Sizing, Node Sizing is affected by operations that split color channels (such as the splitter/combiner nodes) and limit the image (such as qualifiers and windows). You can also add as many node sizing adjustments to a clip's grade as you need.
- **Reference Sizing:** A set of sizing controls that lets you reposition the still when a wipe comparison is being made. Using these controls, you can move the still image to better compare it to the clip you're wiping it against. The Reference Sizing controls only work when you have a wipe enabled.

Sizing Order of Processing on the Color Page

Input Sizing adjustments are applied before all image processing that takes place in the node graph, including Node Sizing, while Output Sizing adjustments are applied after image processing in the node graph.

Sizing Controls

Input, Node, and Output Sizing share many of the same controls. When the Sizing palette is set to Input Sizing mode, the controls transform each clip individually. If you're simply pushing in on one or two clips, or making individual pan and scan adjustments to account for a change in format, these are the controls you want to use.

The Sizing palette

- **Pan:** Moves the clip along the horizontal, X axis. Positive values move the clip right, negative values move the clip left.
- **Tilt:** Moves the clip along the vertical, Y axis. Positive values move the clip up, negative values move the clip down.
- **Zoom:** Adjusts the overall dimensions of the clip. The range is from 0.250 (1/4x size) to 4.000 (4x size). Normal size is 1.000.
- **Rotate:** Positive values rotate the clip clockwise. Negative values rotate the clip counter-clockwise.
- **Width:** Stretches the image wider or narrower. The range is from 0.250 (1/4x width) to 4.000 (4x width). Normal width is 1.000.
- **Height:** Stretches the image taller or shorter. The range is from 0.250 (1/4x height) to 4.000 (4x height). Normal height is 1.000.
- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and push the right of the image forward. Higher values stretch the image more extremely.
- **Key Lock:** (Node Sizing only) Lets you choose how regions of the image that are isolated by one or more windows will be transformed. There are two options:

  Off: While off, the transform controls will move the windowed region to another area of the frame, effectively duplicating the windowed area.

  On: While on, the transform controls will move other areas of the frame into the windowed regions, effectively covering up the windowed area with another portion of the picture.

- **Flip Image:** Two buttons let you flip the image in different dimensions.

  Flip Horizontal control: Reverses the image along the X axis, left to right.

  Flip Vertical control: Reverses the clip along the Y axis, turning it upside down.

- **Lens Correction:** (Edit Sizing only) Two controls let you correct for lens distortion in the image, or add lens distortion of your own (only available in the Studio version).

  Analyze: Automatically analyzes the frame in the Timeline at the position of the playhead for edges that are being distorted by wide angle lens. Clicking the Analyze button modifies the effect of the Distortion slider so that it gives a more accurate result, but it doesn't perform a correction.

  Distortion: Dragging this slider to the right applies a warp to the image that lets you straighten the bent areas of the picture that can be caused by wide angle lenses. It's not necessary to click the Analyze button prior to using this slider, but using the Analyze button can improve the accuracy of the result.

Blanking Controls

Output Sizing mode also has a set of Blanking controls that you can use to add custom blanking to a clip or project. For example, you can use these controls to add nonstandard letterboxing or pillarboxing to an image. Along with all other Output Sizing adjustments, blanking is added last in the image processing pipeline, so it's not affected by any of the color or contrast adjustments you make.

- **Top:** Adjusts the top letterbox.
- **Right:** Adjusts the right pillarbox.
- **Bottom:** Adjusts the bottom letterbox.

- **Left:** Adjusts the left pillarbox.
- **Smooth:** A checkbox that lets you turn on edge anti-aliasing for source blanking. Overrides the Anti-alias Edges drop-down menu found in the Image Scaling panel of the Project Settings.

NOTE: It might be necessary to turn anti-aliasing off if you notice black blurring at the edges of blanking being applied to an image.

Blanking presets are also available by choosing from the Timeline > Output Blanking submenu. Choosing one of these options automatically sets the Blanking parameters of the Sizing palette's Output Sizing mode. The following presets are available:

- **1.33:** SD or 4:3
- **1.66:** European theatrical
- **1.77:** HD or 16:9
- **1.85:** Theatrical flat aspect ratio
- **2.00:** Univisium. Aspect ratio designed to accommodate both theatrical wide-screen and HD delivery.
- **2.35:** Original anamorphic (scope) theatrical wide-screen
- **2.39:** Current 35mm anamorphic (scope) theatrical wide-screen
- **2.40:** Current 35mm anamorphic (scope) theatrical wide-screen (rounded up for Blu-Ray)
- **Reset:** Restores the clip to its original aspect ratio.

Anti-aliasing at the edges of blanking is handled by an Anti-Alias Edges setting in the Image Scaling panel of the Project Settings. For more information, *see Chapter 4, "System and User Preferences."*

Resetting the Sizing Palette

You can reset every control within the Sizing palette at any time by clicking the reset button in the upper right-hand corner of the palette.

Input and Output Sizing Presets

If there are Input or Output Sizing settings that you find yourself using repeatedly, you can save them as presets for easy recall. For example, if there's a group of input settings that you use to resize a clip of a particular format to match the current project, you can save it as a preset that you can use whenever.

- **Preset drop-down menu:** Provides access to all the currently saved presets in the current project library.
- **Delete Preset:** To delete a preset, select it from the drop-down menu, click the trash can button, then click OK.
- **Save As New Preset:** To add a preset, make whatever settings adjustments you need, then click the plus button. When the Format Preset dialog appears, enter a name, check that the settings are correct, then click Save in the Format Preset window.
- **Update Preset:** To change a preset, load the preset you want to change, make whatever changes you need, then click Update in the Format Preset window.

The Input and Output Sizing modes save different presets. Each of these sets of presets is available from the "Override input scaling" and "Override output scaling" drop-down menus in the Image Scaling project setting menu.

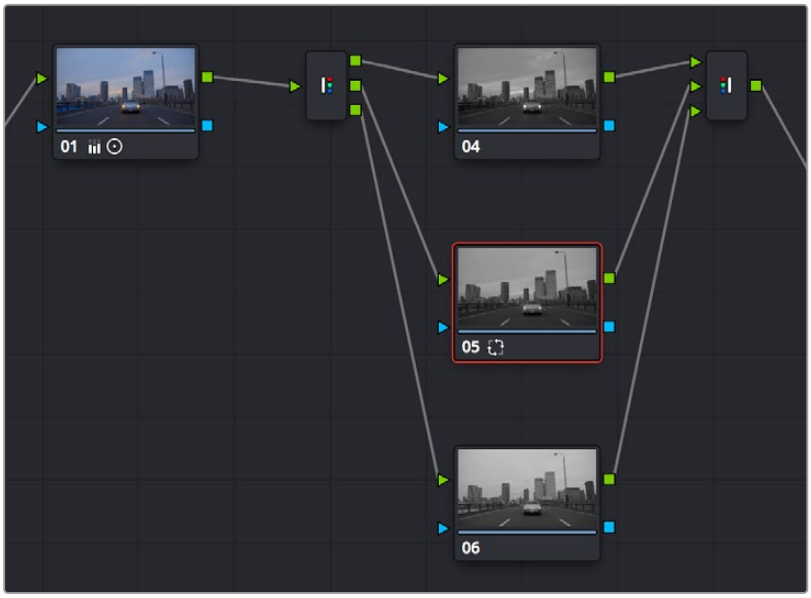
Using Node Sizing for Channel and Paint Effects

Using Node Sizing, you can apply individual sizing adjustments on a per-node basis. All Node Sizing adjustments within a grade are cumulative, and any keyframing done to Node Sizing parameters is stored in that node's Node Format keyframe track in the Keyframe Editor. Two good examples of Node Sizing include realigning color channels individually in conjunction with the Splitter/Combiner nodes, or duplicating windowed regions of an image by moving them around the frame.

Example 1

Using node sizing on individual color channels:

1. Choose Color > Nodes > Add Splitter/Combiner Node to add this node structure to the current grade.
2. Select one of the three Corrector nodes connected between the Splitter and Combiner nodes that corresponds to the color channel you want to transform.



Adding the Splitter/Combiner nodes to use Node Sizing on individual color channels

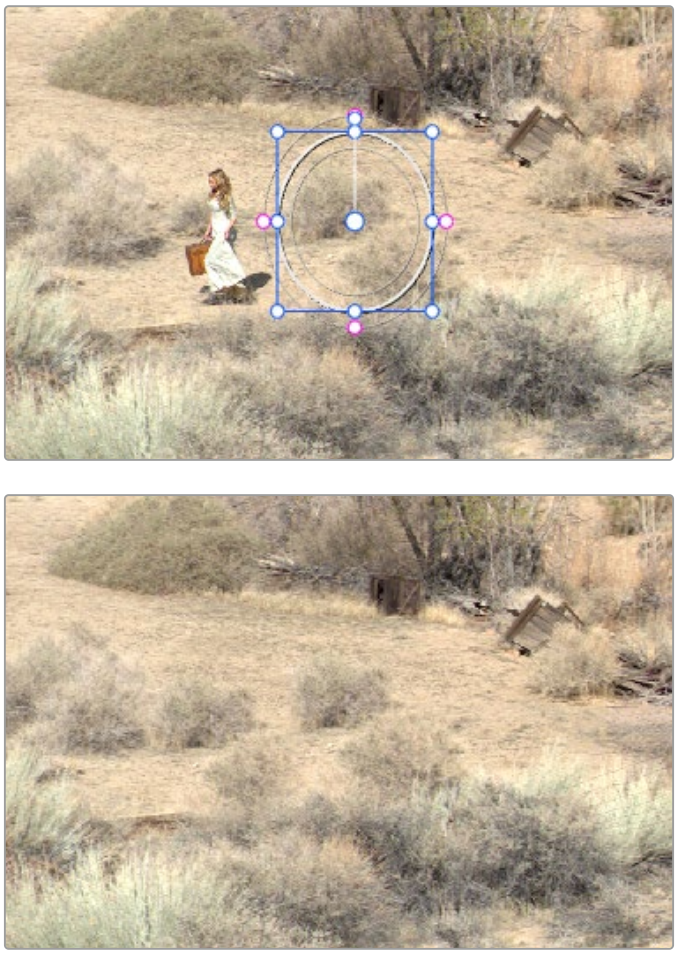
3. Open the Sizing palette, choose Node Sizing from the mode drop-down, and use the Sizing parameters to transform that channel as necessary. For example, if you have an old video clip with misaligned color components, you could pan a misaligned channel to the left or right to try and improve its alignment.

Before and after panning the green channel

Example 2

Using Node Sizing to duplicate a windowed area of an image to cover a blemish:

1. Create a new node.
2. Open the Window palette, create a Circular window, and then shrink and reposition it to surround a feature you want to remove.
3. Open the Tracking palette, and track the window to follow the feature to be removed.
4. After the track is complete, now move the window to an adjacent area of clean detail that's right next to the feature you want to remove. This is the area of the image you're going to duplicate and cover the unwanted feature with.
5. Now, open the Sizing palette, choose Node Sizing from the mode drop-down, check Key Lock, and use the Sizing parameters to move a duplicate of the windowed area to cover up the unwanted feature.



Before/after using Node Sizing to clone an area of the image to cover up the actor with a plant to create a clean background

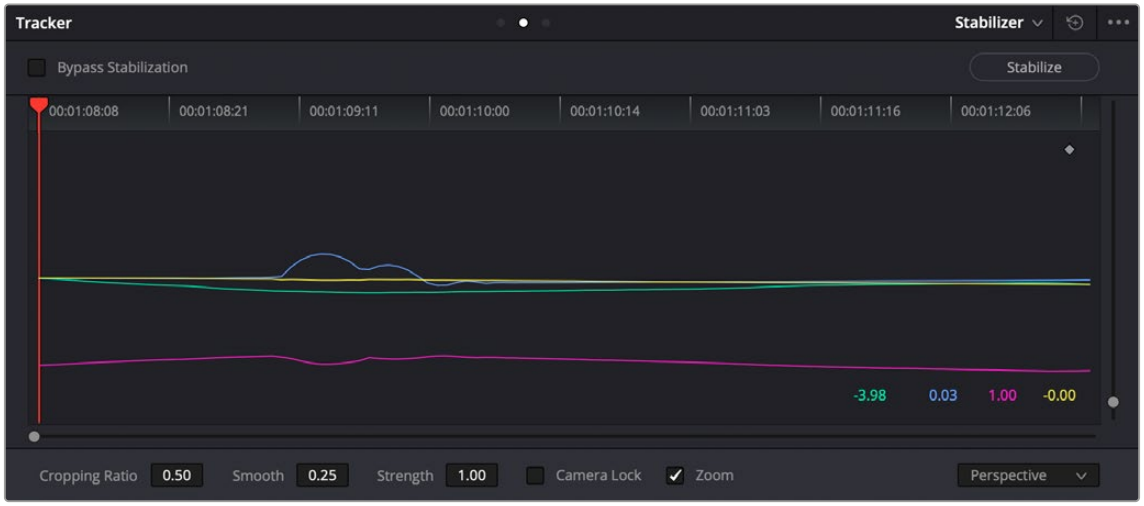
When you're done, playing through the clip should show that the duplicated area of the image is still tracking the feature you want to remove.

Image Stabilization in the Tracker Palette

The Image Stabilization mode of the Tracker palette lets you smooth out or even steady unwanted camera motion within a clip. The analysis is performed in such a way as to preserve the motion of individual subjects within the frame, as well as the overall direction of desirable camera motion, while correcting for unsteadiness.

Using the Stabilizer

DaVinci Resolve uses an advanced stabilizer that's capable of both warping and translation to minimize unwanted shaking in a clip replaces the classic stabilization tools that were available previously (these tools are still available should you need specific capabilities of the older toolset, and are covered in a later section). With a single click of the Stabilize button, the currently selected clip is analyzed and automatically stabilized using a combination of warping and image translations.



The default Stabilizer controls

Stabilizer Parameters and Controls

The default settings yield good results for most situations, but there are ways you can customize stabilization in situations where unique issues arise.

A drop-down menu provides three different options that determine how the selected clip is analyzed and transformed during stabilization. You must choose an option first, before clicking the Stabilize button, because the option you choose changes how the image analysis is performed. If you choose another option, you must click the Stabilize button again to reanalyze the clip.

- **Perspective:** Enables perspective, pan, tilt, zoom, and rotation analysis and stabilization.
- **Similarity:** Enables pan, tilt, zoom, and rotation analysis and stabilization, for instances where perspective analysis results in unwanted motion artifacts.
- **Translation:** Enables pan and tilt analysis and stabilization only, for instances where only X and Y stabilization gives you acceptable results.
- **Camera Gyro:** If your footage is from a Blackmagic Cinema Camera that has a gyroscope, this option will appear in the drop-down menu. You can stabilize the footage based on the movement recorded by the internal gyro that is embedded in the clip.

The other controls let you customize how aggressively the selected clip is stabilized.

- **Bypass Stabilization:** This checkbox lets you turn stabilization off and on to be able to compare the stabilized and unstabilized image.
- **Cropping Ratio:** This value limits how hard the stabilizer tries to stabilize, by dictating how much blanking or zooming you're willing to accept in exchange for eliminating unwanted motion. A value of 1.0 results in no stabilization being applied. Progressively lower values enable more aggressive stabilization. Changing this value requires you to click the Stabilize button again to re-analyze the clip.
- **Smooth:** Lets you apply mathematical smoothing to the analyzed data used to stabilize the clip, allowing camera motion in the shot while eliminating unwanted jittering. Lower values perform less smoothing, allowing more of the character of the original camera motion to show through, while higher values smooth the shot more aggressively. Changing this value requires you to click the Stabilize button again to reanalyze the clip.
- **Strength:** This value is a multiplier that lets you choose how tightly you want to use the stabilization track to eliminate motion from a shot using the current analysis. With a value of 1.00, stabilization is maximized. Since some clips might look more natural with looser stabilization, choosing a number lower than 100 lets a percentage of the original camera motion show through.

Zero (0) disables stabilization altogether. As an additional tip, you can invert the stabilization by choosing –1.00 when pasting a stabilization analysis from another clip to perform a match move based on the overall motion of the scene, and you can use a negative value either lower or higher than –1.00 to under or overcompensate when inverting the stabilization, simulating the effects of parallax where foreground and background planes move together but at different speeds.

- **Camera Lock:** Turning on this checkbox disables Cropping Ratio and Smooth, and enables the stabilizer to focus on eliminating all camera motion from the shot in an effort to create a locked shot.
- **Zoom:** When this checkbox is turned on, the image is resized by a large enough percentage to eliminate the blanking (black edges) that is the result of warping and transforming the image to eliminate unwanted camera motion. The lower a value Cropping Ratio is set to, the more DaVinci Resolve will need to zoom into an image to eliminate these blanked edges. If you turn this off, the image is not zoomed at all, and whatever blanking intrudes into the image is output along with the image, on the assumption that you'll have dedicated compositing artists deal with eliminating this blanking by filling in the missing image data in a more sophisticated manner. You may also leave this checkbox turned off if you're planning on animating the Input Sizing Zoom parameter to dynamically zoom into and out of a shot being stabilized to eliminate blanking only where it occurs, using only as much zooming as is necessary for each region of the shot.

Using the Classic Stabilizer

The "classic" image stabilizer controls available in DaVinci Resolve version 12.5 and earlier are still available, simply select "Classic Stabilizer" from the option menu of the Tracker palette. Classic image stabilization in DaVinci Resolve consists of three steps. First, you analyze the clip. Second, you choose the Stabilization settings you want to use. Third, you click Stabilize to calculate the result.

When analyzing the clip, you can choose to use either the default Cloud Tracker, which automatically finds as many trackable points as possible throughout the image and calculates stabilization based on all of them, or you can use the Point Tracker, which lets you manually place one or more individual crosshairs on image features that you select.

For more information on using the Point Tracker for window tracking, *see Chapter 138, "Motion Tracking Windows."*

The Classic Stabilizer mode of the Tracker palette

As with object tracking, you can choose which aspects of motion to stabilize, but this must be done before you do the initial image analysis.

Analyze Controls

The Analyze controls automatically scan through the entire clip, identifying trackable features that can be used to stabilize the shot.

A series of four checkboxes let you turn on and off which axes you'd like to stabilize. These checkboxes must be selected before you perform an analysis in order to restrict the data that's generated.

- **Pan:** Enables horizontal stabilization.
- **Tilt:** Enables vertical stabilization.
- **Zoom:** Enables stabilization of size.
- **Rotate:** Enables stabilization of orientation.

NOTE: Once stabilization has been done, disabling these checkboxes does nothing to alter the result. To make changes, you need to enable or disable the necessary checkboxes first, and then reanalyze the clip.

The five direction buttons let you perform the stabilization analysis.

- **Track One Frame Reverse:** Initiates tracking from the current frame backward by a duration of one frame.
- **Track Reverse:** Initiates tracking from the current frame backward, ending at the first frame of the clip.
- **Pause:** Stops tracking (if you're fast enough to click this button before tracking is finished).
- **Track Forward:** Initiates tracking from the current frame forward, ending at the last frame of the clip.
- **Track One Frame Forward:** Initiates tracking from the current frame forward by a duration of one frame.

Interactive Mode Controls

The Interactive controls let you make manual changes to the automatically generated tracking point cloud that DaVinci Resolve creates, so you can try different ways of obtaining better stabilization results in challenging situations.

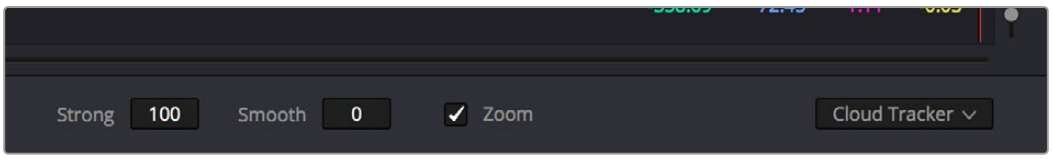
- **Interactive Mode checkbox:** Turns the Interactive stabilization mode on and off. When you enter Interactive mode, you can manually alter the point cloud that DaVinci Resolve uses to stabilize the image. You'll then make your analysis while in Interactive mode. When you exit Interactive mode, your manual changes to the point cloud are eliminated, and DaVinci Resolve again uses automatically placed point clouds to do all stabilization.
- **Insert:** Lets you add tracking points to whatever analyzable features exist within a bounding box that you've drawn in the Viewer. Inserted stabilization points are automatically placed.
- **Set Point:** Lets you use the cursor (using the DaVinci Resolve control panel), to manually place individual tracking points, one by one, with which to track a feature. If there is no trackable pixel group at the coordinates where you placed the cursor, a tracking point will be placed at the nearest trackable pixel group. You must place at least two tracking points at different pixel groups to track rotation, and at least three to track zoom.
- **Delete:** Eliminates all stabilization points within a bounding box that you've drawn in the Viewer.

The procedures for using Interactive mode for stabilization are the same as for tracking.

For more information, *see Chapter 138, "Motion Tracking Windows."*

Stabilization Parameters and Controls

There are five controls in the Stabilization group:



Stabilization selections

- **Strong:** Lets you choose how tightly you want to use the stabilization track to eliminate motion from a shot. With a value of 100, stabilization is maximized in an effort to "lock" the shot in place and eliminate all camera motion. This value is a multiplier. Since some clips might look more natural with looser stabilization, choosing a number lower than 100 lets a percentage of the original camera motion show through. Zero (0) disables stabilization altogether. Additionally, you can invert the stabilization by choosing –100, as described in the section on performing a match move below, and you can use a negative value either lower or higher than –100 to under or overcompensate when inverting the stabilization, simulating the effects of parallax where foreground and background planes move together but at different speeds.
- **Smooth:** Lets you apply mathematical smoothing to the analyzed data used to stabilize the clip, and is meant to be used when the Strong parameter is less than 100, allowing camera motion in the shot while eliminating unwanted wiggling. Lower values perform less smoothing, allowing more of the character of the original camera motion to show through, while higher values smooth the shot more aggressively.
- **Zoom:** When this checkbox is turned on, the image is resized by a large enough percentage to eliminate the blanking (black edges) that is the result of repositioning the image to eliminate unwanted camera motion. The higher a value Smooth Frames is set to, the more DaVinci Resolve will need to zoom into an image to eliminate these blanked edges. If you turn this off, the image is not zoomed at all, and whatever blanking intrudes into the image is output along with the image, on the assumption that you'll have dedicated compositing artists deal with eliminating this blanking by filling in the missing image data in a more sophisticated manner. You may also leave this checkbox turned off if you're planning on animating the Input Sizing Zoom parameter to dynamically zoom into and out of a shot being stabilized to eliminate blanking only where it occurs, using only as much zooming as is necessary for each region of the shot.
- **Tracker Type:** A drop-down menu below the Tracker graph lets you choose whether to use the Cloud Tracker or the Point Tracker. The default Cloud Tracker automatically finds as many trackable points as possible throughout the image and calculates stabilization based on all of them. This is fast, but can result in problems if there are too many prominent subjects in the frame with different vectors of motion. The Point Tracker, by contrast, lets you manually place one or more individual crosshairs on image features that you select. This involves more steps, but has the advantage of letting you choose exactly which features exhibit the motion you're trying to stabilize.

  For more information on using the Point Tracker for window tracking, *see Chapter 138, "Motion Tracking Windows."*

- **Stabilize:** After you've tracked the clip and adjusted the previous two controls, you need to click Stabilize to calculate the resulting effect of the Strong, Smooth, and Zoom controls on your clip. Whenever you make changes to the Strong, Smooth, or Zoom parameters, you need to click Stabilize to recalculate the resulting effect on your clip.

Classic Stabilization With the Cloud Tracker

Classic Image stabilization in DaVinci Resolve is easy, but you need to follow a specific series of steps for it to be successful.

To stabilize an image:

1. Open the Tracker palette, and choose Stabilizer from the Palette mode drop-down menu. Select Classic Stabilizer in the option menu. Make sure the Tracker Type drop-down menu at the bottom right of the Tracker palette is set to Cloud Tracker.
2. Turn off any of the Analyze checkboxes (Pan, Tilt, Zoom, Rotate, Perspective 3D) that correspond to transform axes you don't want to smooth.
3. Click the Track Forward button to track the clip forward (or Track Reverse if you'd rather start from the end of the clip and work backward).

Multiple tracking points are automatically placed to analyze the motion of the image for stabilization

This analyzes the clip, but no stabilization is yet applied.

4. Adjust the Strong parameter to reflect what kind of stabilization you want. If you want to eliminate all possible motion from the shot, leave Strong set to 100. If you want to use stabilization to smooth out the shot but leave some motion in the frame, reduce the strong parameter to be less than 100 but greater than 0. This parameter is a multiplier, so higher numbers reflect a higher percentage of smoothing being applied to the clip's range of motion, and lower numbers reflect a lower percentage of smoothing being applied to the original range of motion.
5. If you've set the Strong parameter to a value less than 100 to calm the motion in the shot, rather than lock the shot completely, you can also adjust the Smooth parameter to mathematically smooth what motion remains in the shot. This lets you even out any "wobbling" that you don't want, while retaining the camera motion that you do want. The Strong and Smooth parameters work together, so experiment with different values in each parameter to get the result you need.
6. Choose how you want the edges of the stabilized clip to be handled using the Zoom checkbox:
   - If you want DaVinci Resolve to zoom into the image as much as is necessary to prevent blanking (black edges) from intruding into the frame (the result of repositioning the image to steady camera motion), then turn on the Viewer Zoom checkbox.

- If you want to leave the scale of the image alone, allowing blanking (black edges) to intrude into the frame so that you either (a) have an effects artist deal with filling in these holes later, or (b) manually animate the Input Sizing Zoom parameter to eliminate blanking in a dynamic way, then turn off the Viewer Zoom checkbox.

7 With all of these controls adjusted, click Stabilize. The clip is immediately transformed to apply the amount of stabilization you selected via the Smooth Frames slider.

8 Play the clip and examine the stabilization effect. If you need to make any changes, choose new Strong and Smooth Frames values, then click Stabilize. Any time you change any of the Stabilization parameters, you need to click Stabilize to recalculate the resulting transform to your clip.

Classic Stabilizing Using the Point Tracker

For clips in which there are too many moving subjects for the Cloud Tracker to get a solid lock, you need to track a very specific feature in order to successfully stabilize the image. In these cases, it's often faster to use the Point Tracker for stabilization.

To stabilize an image using the Point Tracker:

1 Open the Tracker palette, and choose Stabilizer from the Palette mode drop-down menu. Select Classic Stabilizer from the option menu.

2 Choose Point Tracker from the Tracker Type drop-down menu at the bottom right of the Tracker palette. This changes the available controls under the tracker graph.

3 Click the Add Tracker Point button to add a crosshairs to the Viewer, and drag it to a high-contrast, angular feature you want to track that's indicative of the overall motion of the clip.

Using the Point Tracker to stabilize an image

> **TIP:** You can optionally add more than one Tracker crosshairs to track multiple features, and DaVinci Resolve will attempt to stabilize as many dimensions as are made possible by the additional trackers. One point lets you stabilize Pan and Tilt. Two points lets you try to stabilize Pan, Tilt, and Rotation. Four points lets you try to stabilize Pan, Tilt, Rotation, and Zoom.

4 Click the Track Forward button to track the clip forward (or Track Reverse if you'd rather start from the end of the clip and work backward).

This analyzes the feature you chose to track with the crosshairs, but no stabilization is yet applied.

5 Adjust the Strong parameter to reflect what kind of stabilization you want. If you want to eliminate all possible motion from the shot, leave Strong set to 100. If you want to use stabilization to smooth out the shot but leave some motion in the frame, reduce the strong parameter to be less than 100 but greater than 0. This parameter is a multiplier, so higher numbers reflect a higher percentage of smoothing being applied to the clip's range of motion, and lower numbers reflect a lower percentage of smoothing being applied to the original range of motion.

6 If you've set the Strong parameter to a value less than 100 to calm the motion in the shot, rather than lock the shot completely, you can also adjust the Smooth parameter to mathematically smooth what motion remains in the shot. This lets you even out any "wobbling" that you don't want, while retaining the camera motion that you do want. The Strong and Smooth parameters work together, so experiment with different values in each parameter to get the result you need.

7 Choose how you want the edges of the stabilized clip to be handled using the Zoom checkbox:

- If you want DaVinci Resolve to zoom into the image as much as is necessary to prevent blanking (black edges) from intruding into the frame (the result of repositioning the image to steady camera motion), then turn on the Viewer Zoom checkbox.
- If you want to leave the scale of the image alone, allowing blanking (black edges) to intrude into the frame so that you either (a) have an effects artist deal with filling in these holes later, or (b) manually animate the Input Sizing Zoom parameter to eliminate blanking in a dynamic way, then turn off the Viewer Zoom checkbox.

8 With all of these controls adjusted, click Stabilize. The clip is immediately transformed to apply the amount of stabilization you selected via the Smooth Frames slider.

9 Play the clip and examine the stabilization effect. If you need to make any changes, choose new Strong and Smooth Frames values, then click Stabilize. Any time you change any of the Stabilization parameters, you need to click Stabilize to recalculate the resulting transform to your clip.

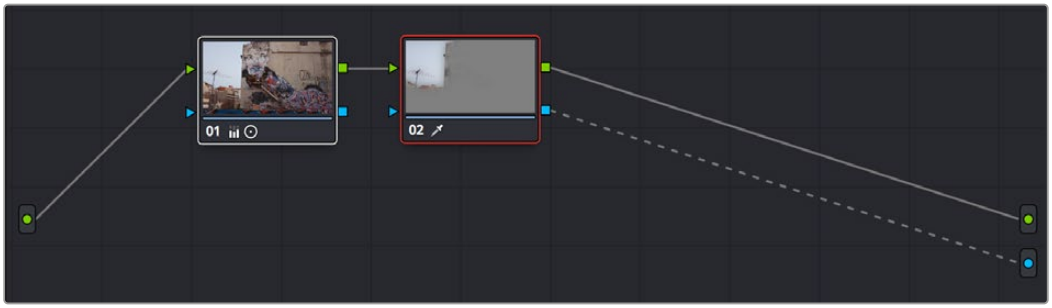
Using Stabilization to Create a Match Move

In some circumstances, such as when you're using the HSL Qualifier to create transparency for a composite (using the Alpha Output described later in this chapter), you may find you need to apply the motion from a foreground clip to the background clip so that the two clips appear to be moving as one. This is referred to as doing a "match move," and is a necessary step when creating a composite for purposes of doing a sky replacement, for example. This can be done in a simple way using the Stabilizer mode of the Tracker palette.

To match the motion of a background clip to a foreground clip:

1 First, in the Edit page, edit a foreground clip onto track V2, and a background clip with a more interesting sky onto track V1.

2 With that done, open the Color page and follow the instructions in the section titled "Using a Qualifier Key to Create Transparency" *see Chapter 145, "Channel Splitting and Image Compositing,"* to key the sky, and use that key to create a region of transparency in the foreground clip that lets the background sky clip in track V1 show through.



Creating transparency to replace the sky in a superimposed clip with a sky image edited into a lower video track

In this example, the plain blue sky is being keyed so that it can be replaced with a more interesting photo of a dramatically cloudy sky.

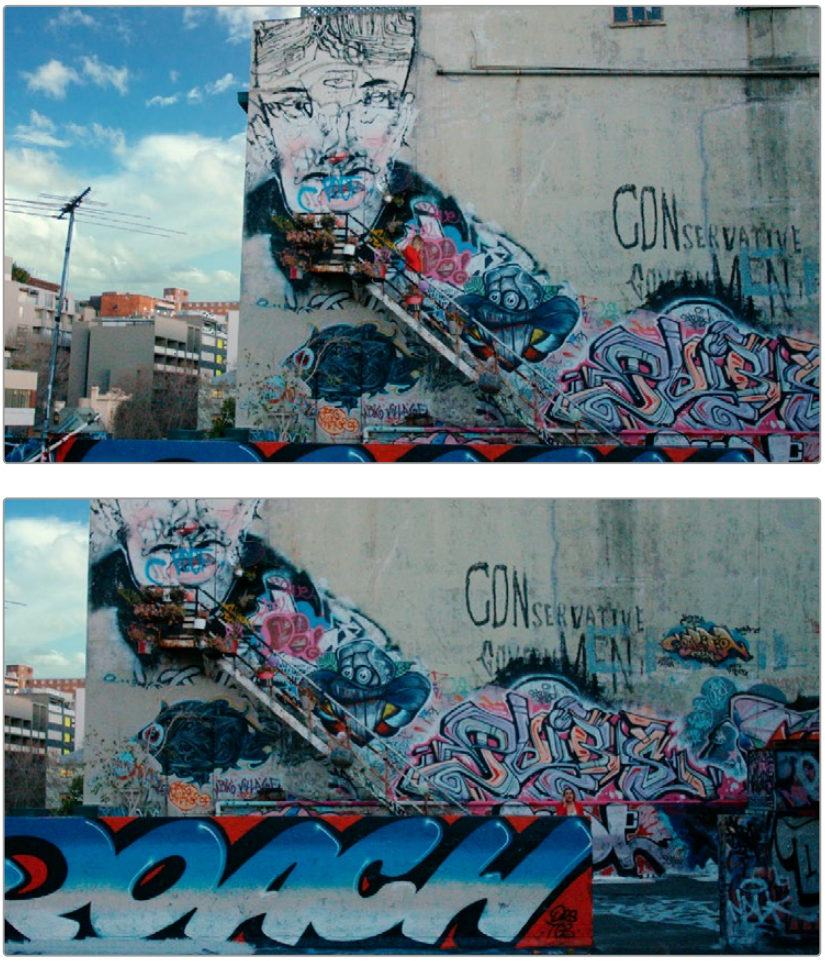
Before and after setting up a sky replacement by connecting an HSL qualifier of the blue in the sky to the Alpha Output to create transparency

This procedure works equally well with still images or movie clips. Also, depending on the range of motion you're going to be matching, you'll probably need to use a background image that's somewhat larger than the region you're keying, to make sure you have full coverage as the layer moves to match the foreground motion. If necessary, you can zoom into the image using the Zoom parameter in the Transform section of the Edit page Inspector.

3. In this example, the foreground clip happens to have a camera pan, which gives the composite away as the sky doesn't move along with it. To move the compound clip of the sky image to match this pan, open the Tracker pallet.
4. Choose its Stabilizer mode, and then click the Analyze Forward button to analyze the motion of the entire clip. Then, click the Tracker palette's Option menu, and choose Copy Track Data.
5. Select the clip that you want to match (in this case the sky image), then open the Tracker Palette's Option menu and choose Paste Track Data.
6. Now, for this to work correctly, you need to set the Strong parameter to –100, and click the Stabilize button. Setting a negative value inverts the tracking data you copied in step 3, which enables it to become a match move. If you're feeling extra tricky, you can set the Strong parameter to a little less than –100, say –94, which introduces a disparity of foreground and background motion that simulates parallax.

Inverting the Strong parameter with a negative number to create matched motion

At this point, playing through the clip should result in a nicely matched correspondence between the movement of the foreground and background layers.



The background sky layer after it's been matched to the motion of the foreground layer; the sky now follows along with the motion of the camera in the superimposed clip.

Chapter 151

The Motion Effects and Blur Palettes

This chapter covers the Noise Reduction and Motion Blur effects found in the Motion Effects palette. It also goes into detail about the Blur, Sharpen, and Mist features of the Blur palette.

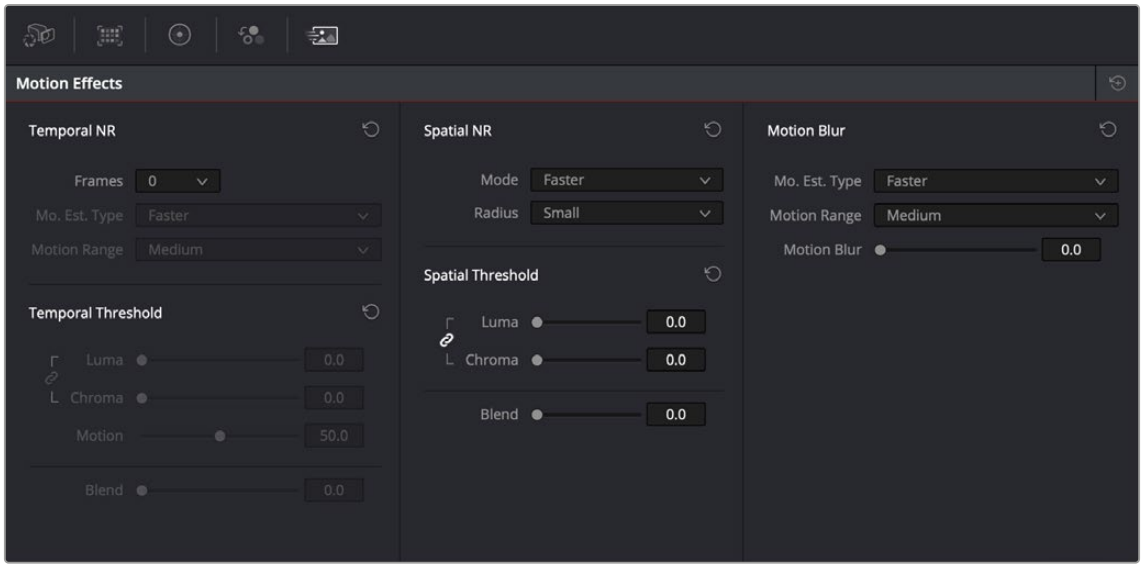
Motion Effects Palette (Studio Version Only)

The Motion Effects palette (only available in the Studio version) contains two sets of controls for applying optical-flow-calculated effects to clips in your program. These include enhanced Spatial and Temporal noise reduction, and motion-estimated artificial motion blur.

Noise Reduction Controls

Two sets of parameters let you apply GPU-accelerated Temporal and/or Spatial noise reduction that's designed to let you subdue noise in problematic clips, in close to real time on workstations with appropriate processing power. Both methods of noise reduction can be used separately or together, in varying amounts depending on the needs of the particular material you're working on. Furthermore, each set of controls is highly customizable, allowing for varying amounts of noise reduction to the chroma and luma of an image, as well as numerous options for how to apply this noise reduction.



Noise Reduction and Motion Blur controls

Temporal NR Controls

The Temporal NR controls analyze images across multiple frames in order to isolate noise from detail. Motion estimation settings let you exclude moving subjects from this operation in order to prevent unwanted motion artifacts.

- **Number of Frames:** The number of frames you want DaVinci Resolve to average in order to separate detail from the noise. You can choose between 0 and 5 frames. 0 applies no frame averaging, higher values apply more frame averaging, at the expense of being significantly more computationally intensive the higher a value you use. Also, a higher frame setting will yield a better analysis, but may yield unwanted artifacts if there are fast-moving images in the frame. A value of 1 may yield better results for fast-moving images. If you need to use higher frame values but you see artifacts, you can also try adjusting the Motion Threshold to fix the issue.
- **Motion Est. Type:** Picks the method DaVinci Resolve uses to detect motion in the image. The default, Faster, is less processor intensive, but less accurate. Choosing Better can effectively exclude motion more accurately, but is more processor intensive. None lets you disable motion estimation altogether, with the result being the application of Temporal NR to the entire image.

- **Motion Range:** Three settings, Small, Medium, and Large, let you set the speed of motion that Motion Estimation should expect to exclude. A Small setting assumes slow-moving subjects with little or no motion blur, allowing Temporal NR to affect more of the image at a given Motion Threshold setting. A Large setting assumes fast motion with blur occupying a larger area of the image, which excludes more of the image from Temporal NR at the same Motion Threshold setting. Choose the setting that gives you the best compromise between a reduction in noise and the introduction of motion artifacts when adjusting the Motion Threshold parameter.
- **Luma Threshold:** Lets you determine how much or how little Temporal NR to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.
- **Chroma Threshold:** Lets you determine how much or how little Temporal NR to apply to the chroma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image, although you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.
- **Luma/Chroma Threshold ganging:** Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, you can ungang these parameters in order to adjust different amounts of noise reduction to each component of the image, depending on where the noise happens to be worst.
- **Motion Threshold:** Defines the threshold separating which moving pixels are in motion (above this threshold) versus which moving pixels are static (below this threshold). Using Motion Estimation, Temporal Noise Reduction is not applied to regions of the image that fall above this threshold, in order to prevent motion artifacts by not applying frame-averaging to parts of the image that are in motion. Lower values omit more of the image from Temporal NR by considering more subtle movements. Higher values apply Temporal NR to more of the image by requiring faster motion for exclusion. You can choose between 0 and 100, where 0 applies Temporal NR to no pixels, and 100 applies Temporal NR to all pixels. The default value is 50, which is a suitable compromise for many clips. Be aware that if you set too high a Motion Threshold, you may see artifacts in moving parts of the image.
- **NR Blend:** Lets you dissolve between the image as it's being affected by the Temporal NR parameters (at 0.0) and the image with no noise reduction at all (100.0). This parameter lets you easily split the difference when using aggressive temporal noise reduction.

Spatial NR Controls

The Spatial NR controls let you smooth out regions of high-frequency noise throughout the image, while attempting to avoid softening by preserving detail. It's effective for reducing noise that Temporal NR can't.

- **Mode:** The Mode drop-down lets you switch Spatial NR between three different algorithms. All three modes of operation use exactly the same controls, so you can switch between modes using the same settings to compare your results.

  Faster: Uses a computationally lightweight method of noise reduction that's good at lower settings, but may produce artifacts when applied at higher values.

  Better: Switches the Spatial NR controls to use a higher quality algorithm that produces greatly superior results to Faster, at the expense of being more processor intensive to render, as well as not allowing you to decouple the Luma and Chroma Threshold sliders for individual adjustments to each color component.

  Enhanced: Does a significantly better job of preserving image sharpness and detail when raising the Spatial Threshold sliders to eliminate noise. This improvement is particularly apparent when the Spatial Threshold sliders are raised to high values (what constitutes "high" varies with the image you're working on). At lower values, the improvement may be more subtle when compared

to the “Better” mode, which is less processor intensive than the computationally expensive “Enhanced” setting. Additionally, “Enhanced” lets you decouple the Luma and Chroma threshold sliders so you can add different amounts of noise reduction to each color component, as the image requires.

UltraNR: UltraNR is an AI-based noise reduction option that provides intelligently targeted noise reduction based on the machine learning of real world video noise patterns, rather than relying on a specific mathematical formula. Its usage is described below.

- **Radius:** Options include Large, Medium, and Small. A smaller radius offers greater real time performance, and can provide good quality when using low Luma and Chroma Threshold values. However, you may see more aliasing in regions of detail when using low NR Threshold values.

  Setting Radius to be progressively larger results in higher quality within areas of greater visual detail at high Luma and Chroma Threshold values, at the expense of slower performance. An NR Radius of Medium should provide suitable quality for most images when using medium NR Threshold settings. As with many operations, there’s an adjustable tradeoff between quality and speed.

- **Luma Threshold:** Lets you determine how much or how little noise reduction to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.
- **Chroma Threshold:** Lets you determine how much or how little noise reduction to apply to the chroma component of the image by smoothing out regions of high-frequency noise while attempting to preserve the sharpness of significant edge details. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image, although you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.
- **Luma/Chroma Threshold ganging:** Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, you can ungang these parameters in order to adjust different amounts of noise reduction to each component of the image.

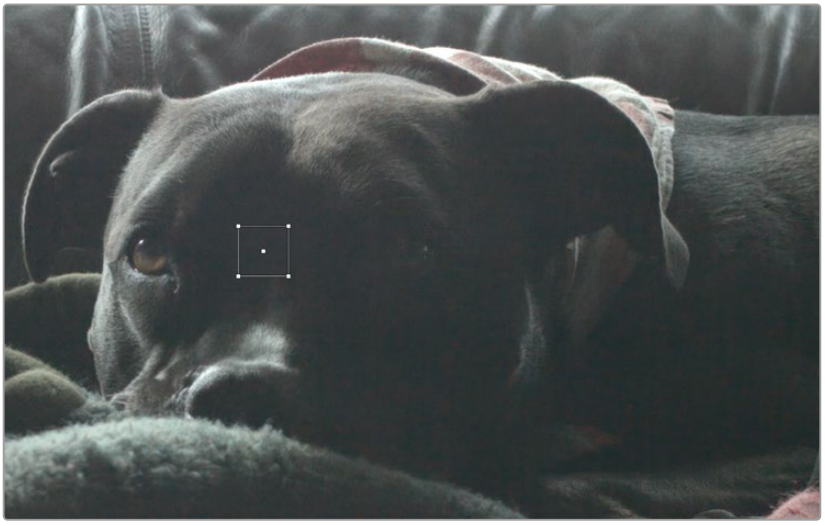
  For example, if an image softens too much at a certain level of noise reduction, but you find there’s more color speckling than there is luma noise, you can lower the Luma Threshold to preserve detail while raising the Chroma Threshold to eliminate color noise.

- **NR Blend:** Lets you dissolve between the image as it’s being affected by the Spatial NR parameters (at 0.0) and the image with no noise reduction at all (100.0). This parameter lets you easily split the difference when using aggressive spatial noise reduction.

UltraNR Noise Reduction

UltraNR is an AI-based noise reduction option that provides intelligently targeted noise reduction based on the machine learning of real world video noise patterns, rather than relying on a specific mathematical formula. This mode should give by far the best results for excessively noisy footage, as well as slightly better results with normal noise reduction. It’s designed to give an optimum balance between the wanted reduction of noise and the unwanted softening of the picture.

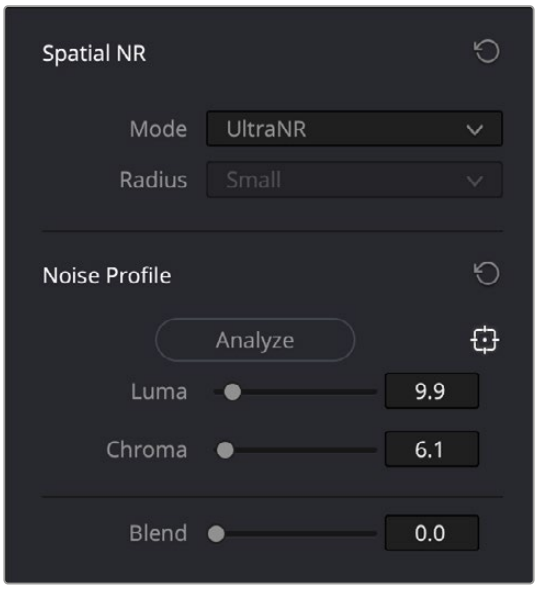
An under-exposed shot of a black dog, on a black blanket, on a black couch. The perfect storm for video noise, as seen above.



The same shot but with the UltraNR mode in the Spatial NR settings. The Show Patch icon has been selected, showing a white box around where the noise pattern is being sampled.

Using UltraNR Controls

UltraNR is applied simply by selecting from the drop-down menu in the Mode section of SpatialNR. You then just need to click on the Analyze button and UltraNR automatically analyzes a flat area of the image that it samples to detect Luma/Chroma noise level and sets the analysis Luma and Chroma sliders appropriately.



The UltraNR control set in the
Color page Motion Effects pane

If your results need further refinement, you can use Auto to detect the flat area and then enable the "Show Patch" icon. A small white outline square appears on your clip, showing you where the AI has placed its analysis point. You can then manually drag the patch (or also change its size a bit by dragging the handles) around flat areas to detect the Luma/Chroma noise level. When you release the mouse button, the luma and chroma for the new box location is calculated. If the results are not ideal, then adjust the sliders to vary the analyzed luma and chroma a bit, adjusting luma first and then chroma. Once you are satisfied with the results, you can hide the patch.

The new UltraNR mode for spatial denoising is available in the Color page in the Motion Effects > Spatial NR pane, and in the Resolve FX noise reduction effect.

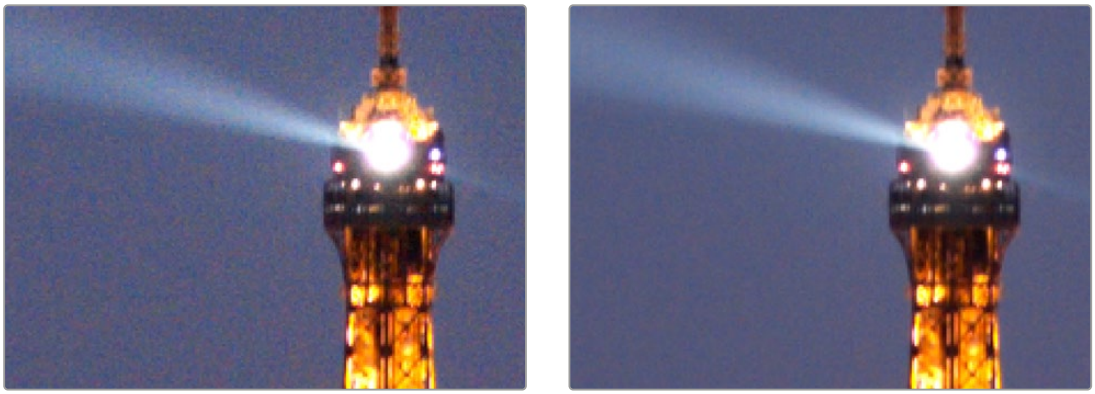
Using Noise Reduction

The following procedure suggests a method of using the Noise Reduction (NR) parameters to achieve a controlled result.

Applying noise reduction to an image:

1. Enable Temporal NR by choosing 1 to 5 frames from the Number of Frames drop-down menu. Keep in mind that more frames dramatically increase the render time of this effect, while it may or may not significantly improve the result, depending on your material.
2. Choose options from the Motion Est. Type and Motion Range drop-down menus corresponding to how much motion is in the image. If there's a lot of motion, you may need to choose Better and Large. If there's not very much motion, lesser settings may suffice.
3. With Luma and Chroma Threshold linked, slowly raise either parameter until you just start to see a reduction in noise within the nonmoving areas of the image, then make smaller adjustments to determine the maximum amount of Temporal NR you can add without creating motion artifacts, or overly softening image detail you want to preserve.
4. If there's obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to apply more aggressive Temporal NR to address color speckling in the picture.

5 If you're not satisfied with the tradeoff between the maximum possible threshold of noise reduction and the prevention of motion artifacts, you may want to adjust the Motion Threshold setting, lowering it to omit more of the motion from the noise reduction operation, or raising it to include more motion. If you're still not satisfied, you can also try better Motion Est. Type and Motion Range settings.



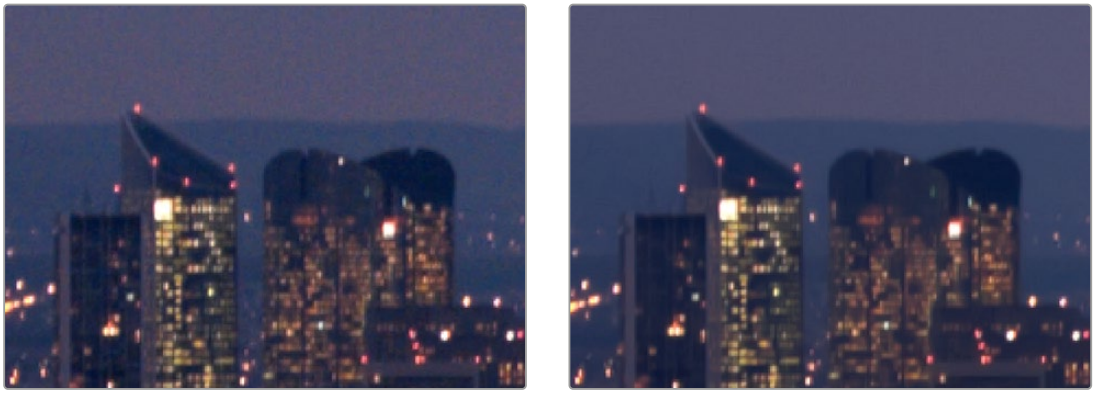
(Left) Before and (Right) after Temporal NR to reduce noise in unmoving areas of the image

Keep in mind that the strength of Temporal NR is to reduce noise in unmoving parts of the image. When you've achieve the best tradeoff between noise reduction in the still areas and avoidance of motion artifacts in the moving areas of the image, then it's time to turn to Spatial NR to further eliminate noise throughout the rest of the picture.

6 Enable Spatial NR by raising either the Luma or Chroma Threshold parameters, which are linked by default, until you strike a suitable balance between the reduction of noise, and an unwanted increase in image softness.

7 It's recommended to choose the Enhanced option from the Spatial NR mode drop-down, as it will yield the best possible results. However, this can be processor-intensive, so if you need better real-time performance, you can switch the mode to Faster and compare results.

8 If there's obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to apply more aggressive Spatial NR to address color speckling in the picture.



(Left) Before and (Right) after noise reduction improves the "look"

9 If you've had to use a high Spatial NR Luma or Chroma Threshold setting to reduce noise visibly, and areas of detail look a bit chunky or aliased, you can choose a larger setting from the Radius drop-down menu to enable a more detailed analysis of the scene.

This will result in higher visual quality, but larger NR Radius settings are more processor intensive, and may reduce real time performance if you don't have adequate GPU resources available to your system.

10 If you've found suitable noise reduction settings, but the result is too aggressive and makes the image appear too processed, you can try raising the Spatial NR and/or Temporal NR Blend parameters to fade between the noise reduction added by each set of controls, and the image as it was before you added noise reduction.

Try Applying Temporal NR First, then Applying Spatial NR

Because Temporal NR analyzes multiple frames for its noise isolation, it tends to be better at preserving detail accurately in regions of the image where there's little motion. If you try applying Temporal NR first and get a successful result, even if only in part of the image, you may reduce how much Spatial NR you have to apply, thus improving the overall quality of your final result.

Keep in mind that while Temporal NR does a great job in unmoving parts of an image but is less effective when dealing with subjects in motion, Spatial NR is able to reduce noise everywhere in the frame falling below its threshold, even when there's motion. Ultimately, a combination of the two is almost always going to be a winning combination.

Spatial NR Radius, How Large Should You Go?

Larger NR Radius settings can dramatically improve the quality of high-detail regions in shots where you're using aggressive Spatial noise reduction, but it's not necessary to always jump to the large Radius setting, which provides the highest precision. In many cases, when evaluating an image that you're applying noise reduction to, you may not actually be able to perceive the additional quality, and you'll waste processing time on an unnecessary level of correction.

It's a good idea to make sure that you're evaluating the full-frame image on a large enough display to see the noise you're working on within the viewing context of the intended audience. Zooming really far into a clip while applying noise reduction may encourage you to use higher quality settings than are necessary, because an excessively enlarged detail of an image lets you see subtle changes that you wouldn't notice at actual size.

Limiting Noise Reduction in Useful Ways

As with any other correction in the Color page, noise reduction can be limited using HSL Qualification or Power Windows. This means you can focus your efforts on reducing noise in the most problematic areas of an image (for example, in shadows and background regions), while sparing elements that you don't want to affect (such as faces or better-lit areas of the image).

Furthermore, you can use Spatial NR in lieu of Blur operations to perform a subtler form of complexion smoothing, using the HSL qualifier or a window to isolate an actor's skin tone for targeted noise reduction.

Controlling the Order of Operations for Noise Reduction

You can apply noise reduction at any point in your image processing tree using a dedicated node. If you have an image with noise that you think might be enhanced by whatever corrections you need to make (increasing the contrast of underexposed clips often increases whatever noise is within an image), there are two approaches to noise reduction:

- **Apply noise reduction at the beginning of a node tree:** This lets you pre-emptively eliminate any noise before it becomes a problem as a result of whatever adjustments you're planning to make. The result can be smoother, but you may also notice that the edge detail within the image is a bit softer.

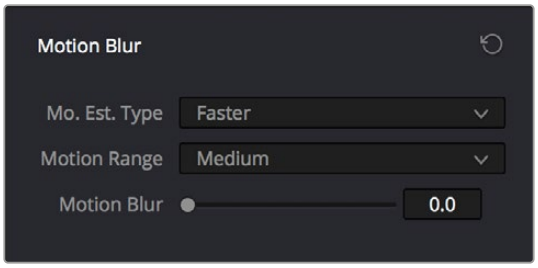
- **Apply noise reduction at the end of a node tree:** The alternative is to make your adjustments first, and then apply noise reduction in a separate node afterwards. In this case, you may find that the noise reduced regions of the image aren't quite as smooth, however the edge detail within the image may be visibly sharper as a result.
- **Apply noise reduction to only one color channel of an image:** Using the Splitter/Combiner nodes, you can also apply noise reduction to only one color component of an image. If you're grading a video clip with a noisy Blue channel, this can be a way to focus noise reduction where it's needed. Isolating a single color channel for noise reduction is also possible using the Channels selection when right-clicking a node. By selecting the specific channel numbers in this node corresponding to your color space (RGB, YUV, LAB, etc.), you can limit the noise reduction operation to the appropriate channels only.

Neither result is universally better or worse than the other. Which is preferable depends on the image you're working on, and the type of result you're looking for (you might prefer some shots to be a bit softer, while you'd like other shots to be a bit sharper). The real point is that the node-based image processing of DaVinci Resolve lets you choose which technique works best for you.

NOTE: If you apply noise reduction and make color adjustments within the same node, noise reduction is processed first, followed by color adjustments.

Motion Blur

Motion Blur settings use optical-flow based motion estimation to add artificial motion blur to clips that have none. This can be useful in cases where a program was shot using a fast shutter speed, and you later decide that the resulting video has too much strobing. By analyzing the motion within a clip, the Motion Blur settings can selectively apply blurring to the image based on the speed and direction of each moving element within the scene.



Motion Blur controls

Three parameters let you set how much motion blur to add, and at what quality:

- **Motion Est. Type:** A setting of Better provides more accurate pixel mapping at the expense of being more processor intensive. Faster provides a more approximate result, but is less processor intensive.
- **Motion Range:** Determines what speed of motion to consider when defining regions being blurred.
- **Motion Blur:** Raise this parameter to add more motion blur to the image, lower it to add less. The range is 0–100, where 0 applies no motion blur, and 100 applies maximum motion blur.

The Blur Palette

The Blur palette has three different modes of operation—blur, sharpen, and mist. While the functionality of the Blur and Sharpen modes somewhat overlap, each mode provides dedicated controls that the other ones lack.

As with virtually everything else in the Color page, the operations performed in the Blur palette can be limited as a secondary operation using HSL Qualifiers, Windows, or Imported mattes, which makes it easy to apply these effects to specific portions of the image.

Many of the controls in the Blur palette consist of three ganged sliders, one for red, one for green, and one for blue.

By default, these ganged sliders move together as one, resulting in each color channel of the image being equally affected. A small white button to the left of each control's name lets you ungang these sliders, in order to apply degrees of adjustment to individual color channels.

Blur

The default mode, Blur lets you apply an exceptionally high-quality Gaussian blur, or another equally high-quality sharpening operation to your image. This mode of operation has the simplest controls.

Blur Radius controls are ganged by default, but can be unganged

Two sets of linked parameters let you adjust the extent and directionality of blur or sharpening. Which is applied depends on the direction in which you adjust the Radius control.

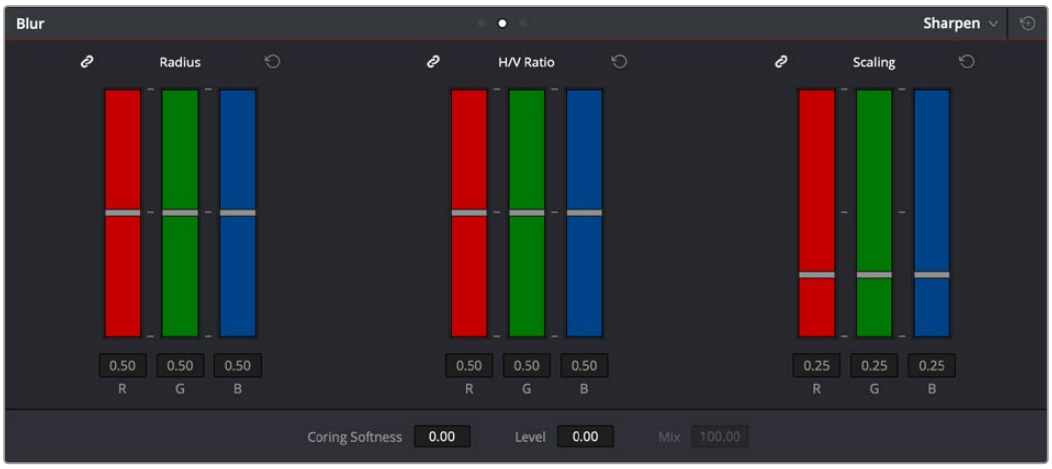
- **Radius:** This is the primary control for adding blur or sharpening. The default value of 0.50 results in no effect being applied to the image. Raising the radius slider increases blur, while lowering the radius increases sharpness, with a minimum value of 0.00 providing maximum sharpness.

  TIP: If you raise the Radius slider all the way to 1.00 and the image isn't blurred enough, add another node and use it to add another blur operation. You can also use the scroll wheel on your mouse while hovering over one of the bars to increase the radius.

- **H/V Ratio:** Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.

Sharpen

While the Blur controls also let you apply sharpening simply by lowering, rather than raising, the Radius sliders, the actual Sharpen mode provides additional controls specifically for tailoring sharpening operations.



Sharpening with Coring Softness and Level

- **Radius:** This is the primary control for adding blur or sharpening. The default value of 0.50 results in no effect being applied to the image. Raising the radius slider increases blur, to a maximum value of 1.00. Lowering the radius increases sharpness, with a minimum value of 0.00 providing maximum sharpness.
- **H/V Ratio:** Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.
- **Scaling:** Multiplies the amount of scaling being applied by the Radius control for sharpening operations. The scaling parameter has no effect if Radius is set to 0.50 or above for blur effects.

The Coring Softness and Level parameters work together to let you limit sharpening to only the most detailed areas of the picture that would most benefit from it, based on a threshold of image detail that you define using the Level and Softness parameters.

- **Level:** The first slider you should use. Raising this value sets the threshold at which image detail is omitted from the sharpening operation. The default setting of 0 sets the threshold low enough to sharpen the entire image. Raising Level gradually omits low-detail areas of the image, which results in sharpening being restricted to well-defined outlines.
- **Coring Softness:** After you've set the Level slider to an appropriate amount, raising Coring Softness blends the border between parts of the image that are sharpened and parts of the image that are left alone.

Mist

The Mist mode lets you combine blur and sharpen operations in such a way as to create effects similar to those achieved via “Vaseline on the lens” or Pro-Mist optical filters.

Mist including Mist Mix control

Unlike the Blur or Sharpen modes, where the Radius sliders provide immediate access to the desired effect, the Mist mode requires you to lower the Radius and Mix sliders together to get a desirable result. By varying the amounts of Radius and Mix, you can create many variations on the mist effect.

- **Radius:** When creating a Mist effect, you first need to lower Radius to sharpen the image. This operation then combines with a lowering of the Mix parameter to provide the combination of detail and blurring that results in a mist effect.
- **H/V Ratio:** Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.
- **Scaling:** Multiplies the amount of scaling being applied by the Radius control, and lets you intensify a mist effect beyond the Radius slider’s ordinary range. The scaling parameter has no effect if Radius is set to 0.50 or above for blur effects.
- **Mix:** After you sharpen the image using the Radius slider, decreasing the Mix parameter adds a superimposed blur that mixes with the high-detail areas of the picture to create the mist effect.

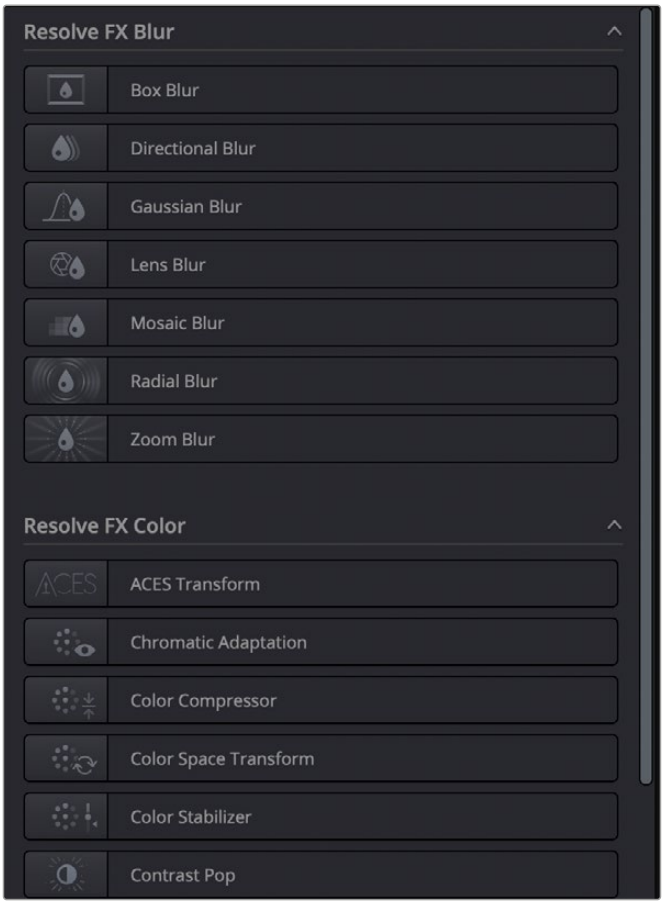
Catalogue of Resolve FX Filters 3305

Show Legacy Resolve FX 3306

Catalogue of Resolve FX Filters

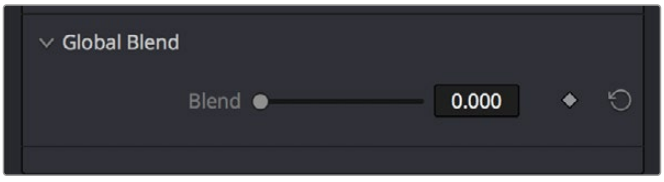
DaVinci Resolve comes with a set of Resolve FX filters, many of which have been optimized for real time playback. These are located within their own category in the Effects Library of the Cut, Edit, and Fusion pages, and in the Open FX browser of the Color page. These effects (or filters) work just like any other Open FX plugin.

Resolve FX are shown as icons depicting each specific filter. Hovering the mouse pointer over the icon previews the filter in the Viewer, and moving the mouse pointer along the icon previews the filter over the length of the clip.



Icons showing categorized Resolve FX filters

In addition to the different parameters built into each filter, every single Resolve FX filter has a Blend parameter that mixes that filter's effect against the original image. Each filter's Blend parameter appears at the bottom of that filter's settings.



The Blend slider found in the parameters of every Resolve FX filter

Show Legacy Resolve FX

Over time some Resolve FX are depreciated for various reasons, such as their functionality being absorbed into another effect or being re-written completely. However, for working on projects that may have used these older effects extensively, or if you're just feeling nostalgic, you still have access to them.

To show the Legacy Resolve FX:

- Open the Effects tab and click on the Effects (3-dot) option menu. Then select Show Legacy Resolve FX. You can remove these effects from the list again by unchecking this setting.

Chapter 153

Resolve FX Blur

The plugins in this category offer a wider variety of different blur methods than those found in the Blur palette.

Box Blur

A variable quality blur that ranges from very low quality to very soft.

- **Horizontal and Vertical Strength:** These sliders let you adjust the width and height of blur.
- **Same Horizontal/Vertical:** This checkbox lets you adjust these parameters together or separately.
- **Horizontal and Vertical Channel Adjustment:** These sliders let you adjust the per channel settings of the blur.

  Red: Adjusts the blur of the Red channel relative to the overall blur.

  Green: Adjusts the blur of the Blue channel relative to the overall blur.

  Blue: Adjusts the blur of the Green channel relative to the overall blur.

  Alpha: Adjusts the blur of the Alpha channel relative to the overall blur.

- **Number of Iterations:** Controls how smooth the resulting blur is, with 1 being the lowest and most "boxy" level of quality and 6 being the highest and smoothest level of quality. At low iteration values, box blurs can appear somewhat similar to lens blurs.
- **Border Type:** Lets you choose how the edges of the image are affected by this blur, options include Black, Replicate, Reflect, and Wrap Around.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image's content.

Directional Blur

A blur that's constrained to a single angle.

- **Blur Strength:** How much blur you want.
- **Blur Angle:** The direction of blur.
- **Blur Type:** When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.
- **Symmetric Blur:** When the Symmetric checkbox is turned on, the blur effect appears to be created from both directions, with the result being more of a double-image that's blurring along the blur angle, simulating motion blur in a camera. When off, the blur effect appears to be moving in a single direction, from the original position out along the blur angle.
- **Channel Adjustment:** Allows you to now set the strength of a blur in a specific channel, relative to the strength of the overall blur.

  Red: Adjusts the blur of the Red channel relative to the overall blur.

  Green: Adjusts the blur of the Blue channel relative to the overall blur.

  Blue: Adjusts the blur of the Green channel relative to the overall blur.

  Alpha: Adjusts the blur of the Alpha channel relative to the overall blur.

- **Border Type:** Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
- **Blur Alpha:** Check this box to blur the alpha channel along with the image's content.

Gaussian Blur

Provides a smooth blur that resembles looking at the image through semi-opaque glass, reducing detail and noise.

- **Horizontal and Vertical Strength:** Two sliders let you adjust the Horizontal and Vertical Strength independently.
- **Same Horizontal/Vertical:** This checkbox lets you keep the Horizontal and Vertical Strength values ganged together.
- **Horizontal and Vertical Channel Adjustment:** These sliders let you adjust the per channel settings of the blur.

  Red: Adjusts the blur of the Red channel relative to the overall blur.

  Green: Adjusts the blur of the Blue channel relative to the overall blur.

  Blue: Adjusts the blur of the Green channel relative to the overall blur.

  Alpha: Adjusts the blur of the Alpha channel relative to the overall blur.
- **Border Type:** Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image's content.

Lens Blur (Studio Version Only)

A high-quality simulation of optical lens blurring. Adjustable parameters let you achieve different kinds of "bokeh" effects, which are similar to those produced by different combinations of aperture design and lens spherical aberration corrections that affect the "circle of confusion" that creates visible shapes in areas of the picture with pinpoint highlights.

Shape

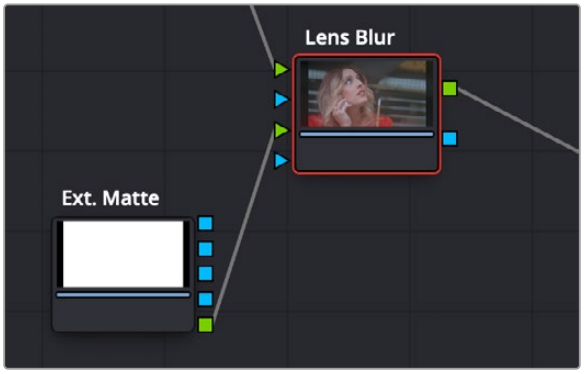
The Shape group lets you choose what shape of aperture to simulate and affects the shape of the bokeh in this effect.

- **Shape Type:** Lets you choose what type of apertures you want to use. There are three options:

  Real Apertures: Lets you choose a realistic option from the Aperture Shape pop-up menu below, with which to influence the shape of the bokeh effect. Aperture Shape options include Triangle, Square, Pentagon, Hexagon, Heptagon, or Octagon shaped aperture.

  Creative: Lets you choose a more fanciful option from the Aperture Shape pop-up menu below, with which to influence the shape of the bokeh effect. These options simulate the kind of bokeh you could realistically achieve by placing a blackout filter with a custom shaped hole in the center in front of a lens. Aperture Shape options include Heart, Star, Starfish, Starburst, Petals, Lip, Eye, Droplet, and Leaf.

  External Input: Uses any arbitrary graphic with a (preferably small) white shape against a black background to influence the shape of the bokeh effect. This shape must be a graphic or matte clip that's added to the Node Editor, then you can attach the image to the second RGB input of the Lens Blur node.



A custom shape used in a color node tree to create custom bokeh in the Lens Blur plugin

- **Aperture Shape:** Provides different options for aperture shapes that influence the shape of this plugin's simulated bokeh blur effect.
- **Preview Shape:** This checkbox lets you see the actual shape you've selected to use.

Speed

The Speed Options group lets you adjust the quality/speed tradeoff of this plugin.

- **Quality:** Three options, Full, Half (Faster), and Quarter (Fast), let you choose a suitable tradeoff between image quality and plugin performance.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image's content.
- **Horizontal and Vertical Crop:** Crops the External Input shape image being used to influence the bokeh to a smaller size, in the event the large size of the graphic is slowing things down and you can crop out extra black from the edges. You won't notice a change to the result until you start cropping into the white part of the shape.

Controls

The parameters available from the Controls group change depending on the Shape Type you've selected.

- **Blur Size/Scale:** Adjusts the overall amount of blur. At higher values, the shape of bokeh can be more clearly seen.
- **Blade Curvature:** (Only available with Real and Creative Apertures) Lets you round off the edges of the Aperture Shape you selected.
- **Rotation:** Lets you adjust the angle the shape appears at.
- **Anamorphism:** Lets you adjust the aspect ratio of this effect in order to match the lens blur created by anamorphic lenses.
- **Chroma Shift:** Lets you simulate chromatic aberration within the blur effect.
- **Highlights:** Lets you adjust how the highlights of the image affect the blur, dilating or eroding the image more or less depending on how high Smooth Strength is.
- **Apodization:** (Only available with Real and Creative Apertures) A slider that lets you adjust the simulated "Airy disk" pattern in the defocused effect being generated. Dragging the slider to the left toward negative values accentuate concentric rings around the bokeh pattern that simulate the effects of optical diffraction and add a pattern to the result, while dragging this slider to the right introduces positive values that gradually filter the edges of the simulated bokeh pattern, resulting in a progressively smoother result.

- **Catadioptric:** (Only available with Real and Creative Apertures) A slider that lets you simulate the effect of a shaped mirror element in a Catadioptric telescope to “improve” focus within the defocused bokeh effect this plugin produces. At higher and higher values, the underlying image becomes progressively less blurry, while still being distorted by the bokeh shape being used which results in soft image overlays, creating a very different kind of simulated optical defocusing effect.

Mosaic Blur

A simple, pixelated blur suitable for hiding the face of anonymous witnesses.

- **Pixel Frequency:** Lets you adjust the size of each pixel, thus determining the density and resolution of the resulting grid of pixels.
- **Cell Shape:** Lets you adjust the base shape of the mosaic. The options are Square, Hexagon, and Triangle.
- **Aliasing:** Lets you adjust how tightly each cell samples the area underneath it.
- **X Offset:** Shifts the grid left or right.
- **Y Offset:** Shifts the grid up or down.
- **Aspect:** Adjusts the aspect ratio of the cells.
- **Antialias Result:** With this box checked the effect performs extra processing to get cleaner lines between the cells.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image’s content.
- **Whole Cells Only:** Limits the showing of cells to those cells that are completely inside of a window only.

Radial Blur

A blur effect that simulates the motion blur that would occur were the image spinning around its center point.

- **X and Y Position:** Lets you move the center of the blur.
- **Smooth Strength:** Adjusts how much blurring is applied.
- **Blur Type:** When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.
- **Blur Symmetry:** Three options are available.

  Symmetric: The blur effect appears to be created in both directions, with the result being more of a double-image that’s blurring in an arc around the X/Y Position, simulating motion blur in a camera.

  Clockwise: The blur effect appears to be moving in a single, clockwise direction.

  Anti-Clockwise: The blur effect appears to be moving in a single, counter-clockwise direction.
- **Channel Adjustment:** Allows you to now set the strength of a blur in a specific channel, relative to the strength of the overall blur.

  Red: Adjusts the blur of the Red channel relative to the overall blur.

  Green: Adjusts the blur of the Blue channel relative to the overall blur.

  Blue: Adjusts the blur of the Green channel relative to the overall blur.

  Alpha: Adjusts the blur of the Alpha channel relative to the overall blur.

- **Border Type:** Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
- **Move with Sizing:** Checking this box lets the blur center retain its relative position in the frame if the Input and Editing sizing are changed.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image's content.

Zoom Blur

A blur effect that simulates the motion blur that would occur were a camera moving toward the image.

- **Zoom Amount:** When Blur Type is set to Realistic, this slider becomes bi-directional. The center is 0, or no blur at all. Dragging to the right expands the blur effect outward from the position. Dragging to the left shrinks the image towards the Position, blurring outward from there.
- **Blur Type:** When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.
- **Smooth Strength:** When Blur Type is set to Stylized, this slider controls the strength of the effect. The left is 0, or no blur at all. Dragging to the right expands the blur effect outward from the position. Dragging to the left shrinks the image towards the Position, blurring outward from there.
- **Center Exclusion:** Controls the distance from the XY position that the Zoom Blur begins.
- **Channel Adjustment:** Allows you to now set the strength of a blur in a specific channel, relative to the strength of the overall blur.

  Red: Adjusts the blur of the Red channel relative to the overall blur.

  Green: Adjusts the blur of the Blue channel relative to the overall blur.

  Blue: Adjusts the blur of the Green channel relative to the overall blur.

  Alpha: Adjusts the blur of the Alpha channel relative to the overall blur.
- **Center Position:** Lets you move the center of the blur.
- **Quality:** Choose between Faster, Better, and Enhanced. Better and Enhanced modes are used to improve sharp image content at low blur values. If this does not apply to your footage, Faster will work just as well.
- **Border Type:** Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
- **Move with Sizing:** Checking this box lets the blur center retain its relative position in the frame if the Input and Editing sizing are changed.
- **Blur Alpha:** Check this box to blur the Alpha channel along with the image's content.

Chapter 154

Resolve FX Color

These plugins provide color processing methods that aren't available in any of the Color Page palettes of the Color page and include several color management tools that can be applied outside of Resolve Color Management (RCM).

Contents

Invert Color 3325

ACES Transform

Lets you perform the kind of color transforms that the ACES Input Device Transform and ACES Output Device Transform parameters of the Color Management panel do, without the need to have ACEScc or ACEScct enabled.

- **ACES Version:** When you've chosen one of the ACES color science options, this pop-up becomes available to let you choose which version of ACES you want to use.
- **Input Transform:** This pop-up menu lets you choose which IDT (Input Device Transform) to use to process the image. It presents the same options that are available in the Color Management panel of the Project Settings.
- **Output Transform:** This pop-up menu lets you choose an ODT (Output Device Transform) with which to transform the image data for monitoring on your calibrated display and when exporting a timeline in the Deliver page. It presents the same options that are available in the Color Management panel of the Project Settings.
- **Gamut Compress Type:** This lets you choose the type of ACES Gamut compression applied to the node. Choosing either option can prevent monochromatic highly saturated light sources (LEDs, neon signs, tail lights, etc.) from clipping the gamut.

For more information about the options available in these parameters, *see Chapter 9, "Data Levels, Color Management, and ACES."*

NOTE: This plugin does ACES transforms correctly using the transforms specified by the Academy, whereas the Color Transform plugin does transforms to the ACES color space colormetrically, which is not actually correct for ACES workflows.

Chromatic Adaptation

A Color category plugin that lets you precisely transform an image that has been lit or processed assuming one specific color temperature to another user-selectable color temperature. This transformation alters the appearance of all colors in the image as perceived by the human vision system in the same way that a new illuminant would, whether that illuminant is a light in the environment being recorded or the color temperature of a display on which the image is shown. This plugin is useful for performing specific color temperature transformations as part of color management workflows or for setting up precise color temperature adjustments as part of a creative grade.

- **Method:** The Method pop-up menu provides a variety of different transform methods to choose from, defaulting to CAT02. Each option in the Method pop-up menu uses different measurement datasets to create individual CAT matrixes to guide this transformation. As a result, each method prioritizes different levels of accuracy for different sets of colors. For example:
  - CAT02 has a non-linear component that compensates for the tendency of extremely saturated blues to go purple, a typical weakness of other methods. It usually gives the best result for the widest variety of measured data sets and works best for emissive sources (displays) and dim viewing environments.
  - Bradford Linear is also a commonly used method, albeit one in which extremely saturated blues will go purple during the transform. It works well for both emissive sources in dim environments and for reflective sources (theater screens) and dark environments.

- Von Kries is one of the oldest methods in common use, although it's also one in which extremely saturated blues will go purple during the transform. This, as well as all other methods, are available if you need to match work done in another image processing application.

- **Source/Target Illuminant:** You control this transformation by using pop-up menus to define the Illuminant Type of the source (typically the color temperature the camera was set to), and that of the target that you want to transform the image to. For both sets of controls, you can choose a Standard Illuminant from a list, a Color Temperature via a slider, or CIE 1931 xy coordinate values. This image transform is extremely precise because the image is first transformed from the Timeline Color Space to XYZ, and then it's transformed to match the LMS (long, medium, short) color space that models the cone response of the human eye to colors lit by different illuminants.
- **Current Color Space and Gamma:** This plugin also takes into account the current color space and gamma of the clip, which default to those set for the current timeline. If you wish to change these values, you can do so using the Color Space and Gamma menus.

NOTE: Be aware that all methods listed will match neutral colors perfectly; the only differences lie in how different ranges of saturated color are transformed.

Color Compressor (Studio Version Only)

This filter lets you compress a range of colors toward a single target color. It works best when applied to similarly colored regions that have been isolated with a secondary qualifier or window. For example, if you're adjusting an irregularly lit product such as a soda can or a dress that must have a very specific hue, you can isolate that item and use this filter to push the range of Hue, Saturation, and Luminance closer to the target color that's identified using the color picker.

(Before/After) Using the Color Compressor plugin to compress original range of hues of the jacket into a narrow "target" range within a secondary operation

- **Target Color:** A color control that allows you to choose a specific color or sample a color from the image using the eyedropper. These selected color values are what you want to push all other colors toward.
- **Compress Hue, Compress Saturation, and Compress Luminance:** These sliders let you individually compress the range of colors you're adjusting in the image to more and more

closely match the image. At 0, no compression is applied, at 0.500 the original range of colors in the image have been adjusted to be halfway between their original values and the values of the Target Color, and at 1.000 the original range of colors has been set to be identical to the Target Color.

Color Space Transform

Lets you perform the kind of color transforms that LUTs do, but instead of using lookup tables, this plugin uses the same math used by Resolve Color Management (RCM) in order to do extremely clean color transforms without clipping.

Color Space Transform

Exposes four pop-up menus that let you set an Input Colorspace, Input Gamma, Output Colorspace, and Output Gamma, in order to do controlled transforms from the Input settings to the Output settings, right within a grade. Resolve Color Management does not have to be enabled for you to use this filter. The Swap button lets you quickly reverse the color and gamma space conversion.

Tone Mapping

Tone Mapping Method lets you enable tone mapping to accommodate workflows where you need to transform one color space into another with a dramatically larger or smaller dynamic range by automating an expansion or contraction of image contrast in such a way as to give a pleasing result with no clipping.

- **None:** This setting disables Input DRT Tone Mapping. No tone mapping is applied to the Input to Timeline Color Space conversion at all, resulting in a simple 1:1 mapping to the Timeline Color Space.
- **Clip:** Hard clips all out-of-bounds values.
- **Simple:** Uses a simple curve to perform this transformation, compressing or expanding the highlights and/or shadows of the timeline dynamic range to better fit the output dynamic range. Note that the “Simple” option maps between approximately 5500 nits and 100 nits, so if you’re mapping from an HDR source with more than 5500 nits to an SDR destination there may still be some clipping of the highlights above 5500 nits.
- **Luminance Mapping:** Same as DaVinci, but more accurate when the Input Color Space of all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020.
- **DaVinci:** This option tone maps the transform with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.
- **Saturation Preserving:** This option has a smooth luminance roll-off in the shadows and highlights, but does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color harder. However, because over-saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.

  Sat. Rolloff Start: Lets you set a threshold, in nits (cd/m^2), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.

  Sat. Rolloff Limit: Lets you set a threshold, in nits (cd/m^2), at which the image will be totally desaturated. End of the rolloff.

- **Use Custom Max Input/Output:** Checking these boxes and adjusting the slider below allows you to specify the minimum and maximum luminance of the input image in nits. Using these two sliders together, you can set which value from the Input Gamma is mapped to which value of the Output Gamma.
- **Adaptation:** Used to compensate for large differences in the viewer's state of visual adaptation when viewing a bright image on an HDR display versus seeing that same image on an SDR display. For most "average" images this setting works best set between 0–10. However, when you're converting very bright images (for example, a snow scene at noon), then using a higher value will yield more image detail within the highlights.

Gamut Mapping

Gamut Mapping Method accommodates workflows where you need to transform one color space into another with a dramatically larger or smaller gamut by helping to automate an expansion or contraction of image saturation in such a way as to give a pleasing and naturalistic result with no clipping.

- Choosing None results in no Gamut mapping at all.
- Choosing Saturation Mapping from this menu enables saturation mapping to fit the range of saturation values from the Input Color Space and Gamma into the Output Color Space and Gamma. It enables the Saturation Knee and Saturation Max. controls.
  - The Saturation Knee slider sets the image level at which saturation mapping begins. Below this level, no remapping is applied. All saturation values from this level on up are remapped according to the Saturation Max. slider. A value of 1.0 is maximum saturation in the currently selected output color space.
  - The Saturation Max slider sets the new maximum level to which you want to either raise or lower all saturation values that are above the Saturation Knee setting. A value of 1.0 is maximum saturation in the currently selected output color space.
- Choosing "Clip" hard clips all out-of-gamut values.

NOTE: While this plugin has ACES settings, it does transforms to the ACES color space colormetrically, which is not actually correct for ACES workflows. For actual ACES workflows, use the ACES Transform plugin, which uses transforms specified by the Academy.

Advanced

This drop-down menu exposes the advanced features of the Color Space Transform effect.

- **Apply Forward OOTF:** Check this box to convert the image from scene referred to display referred color management.
- **Apply Inverse OOTF:** Check this box to convert the image from display referred to scene referred color management.
- **Use white point adaptation:** Applies a chromatic adaptation transform to account for different white points between color spaces.
  - Uncheck this box if you simply want to view the input color space's white point unaltered in the output color space. For example, wanting to use a P3-D60 mastered clip inside a P3-D65 timeline for reference purposes.
  - Check this box to apply the chromatic adaptation transform to convert the input white point to match the output color space's white point. For example, wanting a P3-D60 mastered clip to cut in with other clips mastered in a P3-D65 timeline.

Color Stabilizer (Studio Version Only)

Designed to deal with clips that have inconsistencies in exposure and color, caused by manual changes to a lens' aperture setting or by a camera's auto exposure and white balance settings causing unwanted changes to color and brightness in the middle of a shot. The Color Stabilizer plugin analyzes a frame of the clip that represents the desired exposure and color, and automatically adjusts every other frame of the current clip to match the analyzed levels.

IMPORTANT: The Color Stabilizer gives you the best results with clips that don't have clipped highlights. When used in the Color page, it's recommended to grade the image to bring all the highlights you want somewhere at or under a value of 1023, and then apply the Color Stabilizer to a node after this adjustment.

You will want to use the Color Stabilizer before grading the image. Grading before using the Color Stabilizer can give you unpredictable results.

There are two ways of using the Color Stabilizer:

- The easiest way is to choose Entire Frame from the Region of Analysis pop-up menu. Then, move the playhead in the Viewer to the frame that represents the contrast and color you want the entire clip to have, and click the Live Region Analysis button. Now, if you play through the clip, changes in contrast and color should be gone. This method works best for clips where the inconsistency you're trying to eliminate affects the entire picture.
- Another way is to choose Selected Area from the Region of Analysis pop-up menu. This causes an onscreen rectangle to appear that you can resize and position over a specific region you want to sample for the duration of the clip. If the selected feature you're analyzing is moving, then you can use the FX Tracker to track the subject so the selection box follows it (this is important for a consistent result). Once this is set up, move the playhead in the Viewer to the frame that represents the contrast and color you want the entire clip to have, and click the Analyze This Frame.

  Now, if you play through the clip, changes in contrast and color should be gone. This allows you to stabilize the color of the shot, even if dark objects move through the frame or the highlights change level. You can use the selection box to specifically analyze the part of the frame that has the unwanted exposure change, while ignoring the desirable exposure change.

Depending on what option you choose from the Region for Analysis pop-up menu, different additional options appear.

Analysis Region

If you choose "Selected Area" from the Region of Analysis pop-up, a rectangle in the Viewer appears and you can control its position, scale, and size by clicking and dragging on its corners in the Viewer. These on-screen controls let you transform the selection box that defines which part of the image is being analyzed.

Channels to Stabilize

Once you've analyzed the frame that represents the best contrast and color for that clip, the Channels to Stabilize controls let you choose how to make the correction. The What to Stabilize pop-up menu lets you choose between stabilizing White Balance and Brightness, or R, G, B Channels Separately.

- If you choose White Balance and Brightness, two checkboxes let you choose whether or not you want to include Stabilize White Balance and Stabilize Brightness independently from one another.
- If you choose R, G, B channels separately, three checkboxes appear letting for Stabilize Red, Green, and Blue Channel, so you can pick which particular channels you want to correct.

The Stabilize drop-down menu lets you choose how to make the correction, with the options Levels and Contrast, Offset, and Gain, each of which uses a different method to make the necessary correction, so if one method doesn't work for the particular problem your clip is exhibiting, you can try the other methods to try and get a better result.

Captured Analysis Values

Once you've analyzed the frame, another set of parameters appear showing the captured analysis values upon which the automated correction is based, so that you can make manual adjustments if necessary to improve the result. The parameters that are shown depend on the option you chose from the What to Stabilize pop-up menu.

- If you chose White Balance and Brightness, then you'll have a Normalized White Balance color control, and Low Level and High Level sliders.
- If you chose R, G, B Channels Separately, then you'll have Red, Green, and Blue High and Low Level sliders.

Contrast Pop (Studio Version Only)

A more extreme and selective version of the Midtone Detail control found in the Color Wheels palette, designed to add either sharp high-contrast looks, or soft low-contrast looks to a selective portion of the tonal range of the image.

- **Detail Amount:** Lets you choose how much of this effect to apply. At 0, no effect is applied. At positive values progressively sharper contrast is added, while at negative values progressively softer low-contrast is applied.
- **Detail size:** Lets you choose which structures of the image are affected by this localized contrast adjustment, from smaller to larger.
- **Low and High Threshold:** These values let you define what range of image tonality is affected by this filter, allowing you to omit either shadows or highlights from this operation.
- **Softness:** Lets you soften the transition between the affected and unaffected areas of the image.

DCTL (Studio Version Only)

Lets you apply a DCTL wherever you can apply ResolveFX plugins.

> For more information on DCTLs and where they're installed, *see Chapter 196, "Creating DCTL LUTs."*

- **DCTL List:** A pop-up that lets you choose from the available DCTLs installed on your workstation location.

  On Mac OS X: Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/

  On Windows: C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT

  On Linux: /home/resolve/LUT

- **Reload DCTL:** Allows users to refresh the currently loaded DCTL file content. This lets the user make changes in the DCTL using a text editor, then reload it to see the results. It does not refresh the DCTL list; to do so, you must restart the DaVinci Resolve application.

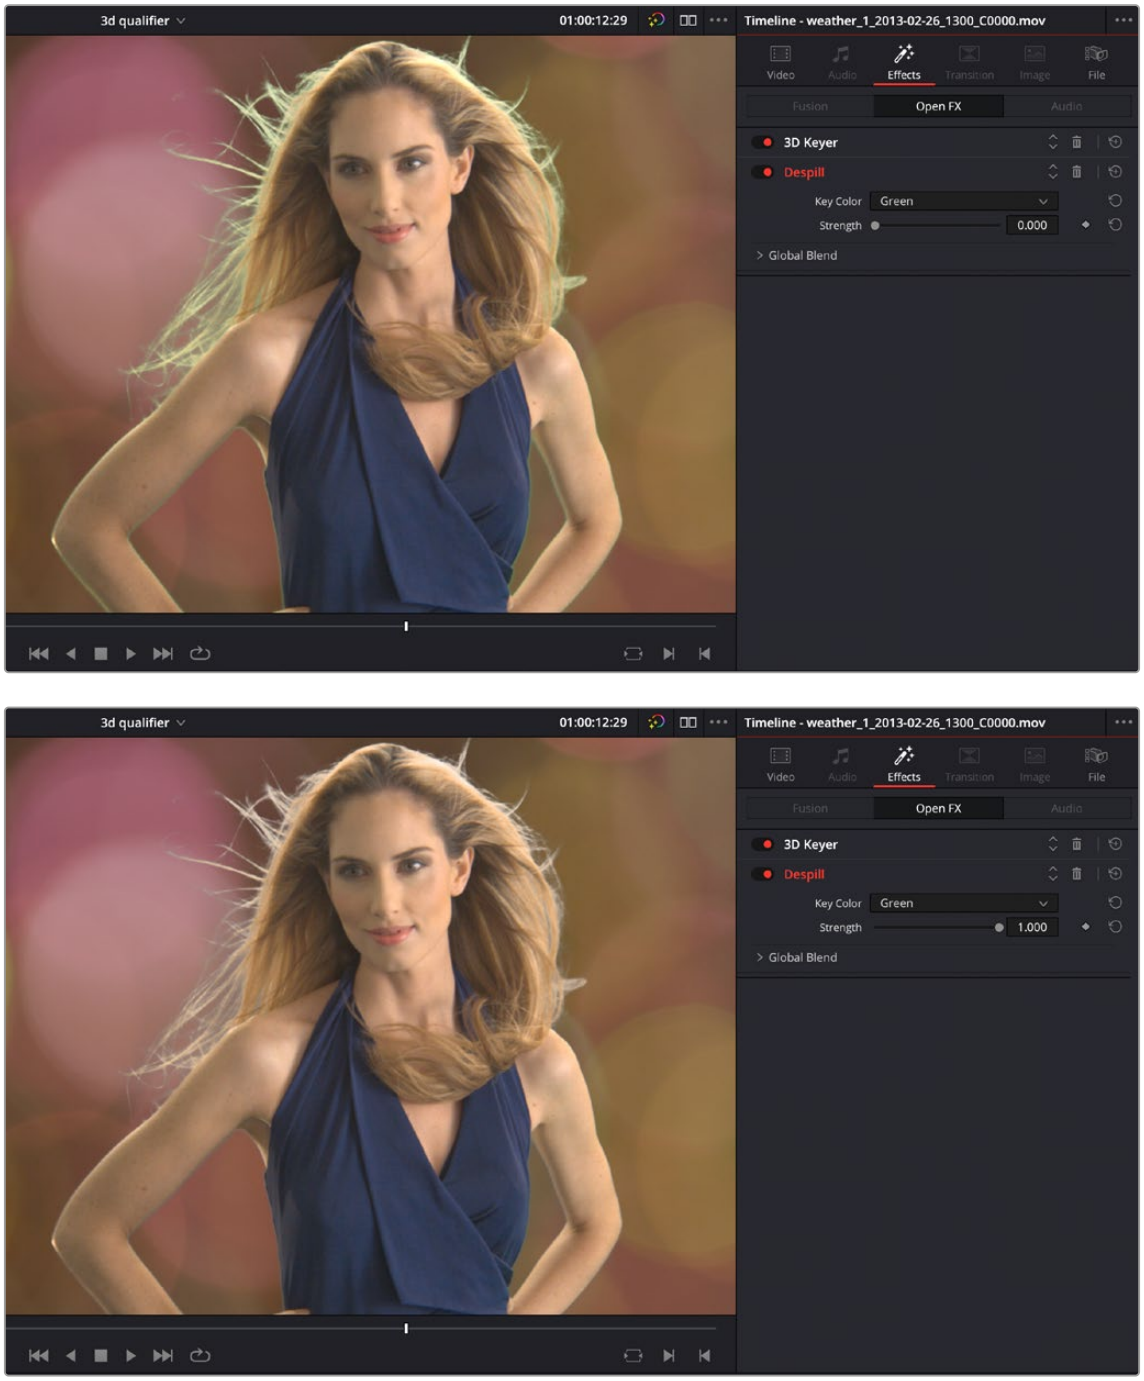
Dehaze (Studio Version Only)

Designed to let you make adjustments to color and contrast to reduce the visible effects of Aerial Perspective (i.e., smog, airlight, and haze) in an image. This filter automatically generates a simulated depth map, which is used to apply more of this corrective color adjustment to faraway parts of the image that would be more affected by haze effects and less color adjustment to closeup parts of the image. It estimates haze and has options for guiding that estimate and controlling the processing.

- **Dehaze Strength:** This slider applies a simultaneous color and contrast adjustment. Raising Dehaze Strength subtly increases contrast (especially in the shadows) while rebalancing color toward the complement of the currently selected Haze Color and selectively intensifying saturation. Lowering Dehaze Strength decreases contrast and rebalances color toward the selected Haze Color itself while selectively lowering saturation.
- **Haze Color:** A color control that lets you choose or sample the color of smog, airlight, or haze in an image that you want to minimize.
- **Display Depth:** Lets you view the simulated depth matte that's being generated. Turn this on before adjusting the Shadow and Highlight controls below.
- **Shadow:** This slider raises or lowers darkest parts of the simulated depth map that defines the parts of the image that are estimated to be farthest away.
- **Highlight:** This slider lets you raise or lower the lightest parts of the simulated depth map that defines the parts of the image that are estimated to be closest to us.

Despill

Removes the color cast on a subject caused by the reflection of light off the green or blue screen. This color cast can remain after the green screen has been keyed out. This Despill filter is useful for reducing spill after keying, or with externally generated keys or masks.



The Despill FX removing a green color cast from the subject's arms and hair. Above is no despill and below is full despill.

- **Key Color:** Sets the color to be removed from the subject, either Red, Green, or Blue.
- **Strength:** The amount of Despill to apply. 1.000 is equal to despill "on" in the previous version of the 3D Keyer checkbox. Variable strength comes in handy as you can preserve more of the original color information if the context allows it. For example, less despill is appropriate if the new composited background will also be green.

False Color (Studio Version Only)

False Color is designed to replicate exactly the false color readout of a Blackmagic Design camera but can also be used as a creative effect that can be used for replicating camera HUDs, infrared sensors, and custom posterization looks by remapping pixel brightness to customizable color bands and gradients. The color set can either match the False Color setting in a specific Blackmagic Design camera or be customized with a list of creative style presets provided for use or inspiration. The presets can be modified by setting the number of colors used and defining the tonal range each color represents.

Resolve FX False Color Camera preset and legend

Resolve FX False Color thermal creative preset and legend

General

- **Plugin Mode:** This menu is used to switch between matching a specific Blackmagic Design Camera's False Color setting or accessing creative presets. When Specific Camera Model is chosen, the Camera Model section is displayed for selecting the camera and settings you want to use. When Creative is chosen, the Color bands section is displayed for choosing and customizing the preset.

Camera Model

The Camera Model controls are displayed when Specific Camera Model is chosen from the Plugin Model menu. These menus allow you to match the False Color from a camera configuration.

- **Camera:** Selects the exact Blackmagic Design camera sensor.
- **Camera Mode:** Selects the dynamic range setting.
- **ISO Level:** Sets the ISO or light sensitivity setting.

Color Bands

These controls are displayed when Creative is chosen from the Plugin Model menu. The Color Bands group of controls are used to select and modify the appearance of the False Color presets.

- **Creative Style:** Selects one of the built-in style presets for the effect.
- **Number of Bands:** Lets you choose how many different colors are in the scale.
- **Show Sliders:** Exposes the Top and Bottom controls letting you select the specific range of a color in percentage values. For example, setting a Red color value between Bottom 45 and Top 55 will tint red anything in the image between 45 and 55% brightness on the waveform monitor.
- **Color:** Provides either a color swatch or picker to choose the color for the band.

Preprocessing

This group of controls is used to apply tonal and blur processing to the image.

- **Blur:** Applies a blur filter to the image before analysis.
- **Black Level:** Increases or decreases the shadow range assigned to colors that fall lower on the False Color legend.
- **White Level:** Increases or decreases the highlight range assigned to colors that fall higher on the False Color legend.
- **Gamma:** Shifts the mid-tone range towards colors that fall lower or higher on the False Color legend.

Scale/Legend

This section is used to control the visibility and appearance of the False Color legend shown at the left of the frame. The Legend shows how dark to light inputs get mapped to new colors. It is burned in to the image.

- **Show Scale:** Shows or hides the Legend.
- **Show Values:** Shows or hides numeric values on the Legend. These numeric values represent different scales based on the Value Style menu.
- **Show Labels:** Shows or hides data point labels on the Legend. The labels identify important data points along the tonal range, such as black clipping, white clipping, and middle gray.
- **Contrast:** Increases or decreases the transparency of the Legend's background underlay.
- **Value Detail:** Increases or decreases the number of axis value labels displayed on the Legend.
- **Value Style:** This menu includes three options for the scale used for the Legend's numeric values.

  Percentage: Uses a percentage scale for the Legend, going from 0% at the bottom to 100% at the top.

  Hundredths: Uses a Hundredths scale for the Legend, going from 0 at the bottom to 100 at the top with no "%" symbol.

  Normalized: Uses a Normalized scale for the Legend, going from 0.0 at the bottom to 1.0 at the top.

Gamut Limiter

Lets you limit the gamut to a specified standard. Useful in situations where the delivery color space is a large gamut such as Rec. 2020, but the QC specification requires limiting to a smaller gamut such as P3, in order to limit the amount of saturation allowable in the final output. This is a limiting operation, so out of bounds values are hard clipped. This plugin can be used regardless of whether or not Resolve Color Management is enabled. Because it's a limiter, it should probably be one of the last operations in any node tree to prevent useful image data from being clipped.

- **Current Gamut:** Choose the timeline gamut currently being used by the image.
- **Current Gamma:** Choose the timeline gamma currently being used by the image.
- **Limit Gamma to:** Choose the gamut you want to restrict the image to here.

These menus present the same options as the Resolve Color Management menus in the Color Management panel.

> For more information about the options available in these parameters, *see Chapter 9, "Data Levels, Color Management, and ACES."*

Gamut Mapping (Studio Version Only)

The Color Space Transform plugin provides Gamut Mapping controls to accommodate workflows where you need to transform one color space into another that has a dramatically larger or smaller gamut. These controls are identical to those found in the Color Space Transform plugin's Gamut Mapping group and are similar to those found in the Color Management panel of the Project Settings.

- **Gamma:** A pop-up menu lets you specify what type of gamma the clip is supposed to have, so set this to whatever matches that image (this may match the timeline color space, but it depends on how you're working).
- **Tone Mapping Method:** Lets you enable tone mapping, to accommodate workflows where you need to transform one color space into another with a dramatically larger or smaller dynamic range by automating an expansion or contraction of image contrast in such a way as to give a pleasing result with no clipping.

  None: This setting disables Input DRT Tone Mapping. No tone mapping is applied to the Input to Timeline Color Space conversion at all, resulting in a simple 1:1 mapping to the Timeline Color Space.

  Clip: Hard clips all out-of-bounds values.

  Simple: Uses a simple curve to perform this transformation, compressing or expanding the highlights and/or shadows of the timeline dynamic range to better fit the output dynamic range. Note that the "Simple" option maps between approximately 5500 nits and 100 nits, so if you're mapping from an HDR source with more than 5500 nits to an SDR destination there may still be some clipping of the highlights above 5500 nits.

  Luminance Mapping: Same as DaVinci, but more accurate when the Input Color Space of all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020.

  DaVinci: This option tone maps the transform with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.

Saturation Preserving: This option has a smooth luminance roll-off in the shadows and highlights, but does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color harder. However, because over-saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.

- **Sat. Rolloff Start:** Lets you set a threshold, in nits (cd/m2), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.
- **Sat. Rolloff Limit:** Lets you set a threshold, in nits (cd/m2), at which the image will be totally desaturated. End of the rolloff.

Max Input/Output Luminance: Checking these boxes and adjusting the slider below allows you to specify the minimum and maximum luminance of the input image in nits. Using these two sliders together, you can set which value from the Input Gamma is mapped to which value of the Output Gamma.

Avg. Input Luminance: Used to compensate for large differences in the viewer's state of visual adaptation when viewing a bright image on an HDR display versus seeing that same image on an SDR display. For most "average" images this setting works best set between 0–10. However, when you're converting very bright images (for example, a snow scene at noon), then using a higher value will yield more image detail within the highlights.

- **Gamut Mapping Method:** Accommodates workflows where you need to transform one color space into another with a dramatically larger or smaller gamut by helping to automate an expansion or contraction of image saturation in such a way as to give a pleasing and naturalistic result with no clipping. Choosing Saturation Mapping lets you remap the saturation values of the image. It enables the Saturation Knee and Saturation Max. controls.
  - The Saturation Knee slider sets the image level at which saturation mapping begins. Below this level, no remapping is applied. All saturation values from this level on up are remapped according to the Saturation Max. slider. A value of 1.0 is maximum saturation in the currently selected output color space.
  - The Saturation Max slider sets the new maximum level to which you want to either raise or lower all saturation values that are above the Saturation Knee setting. A value of 1.0 is maximum saturation in the currently selected output color space.
- **Apply Forward OOTF:** Check this box to convert the image from scene referred to display referred color management.
- **Apply Inverse OOTF:** Check this box to convert the image from display referred to scene referred color management.

Invert Color

A Color category plugin that lets you invert any color channel, including the Alpha channel just by checking the appropriate box. This little plugin has 101 uses in advanced workflows, especially when you need to invert Alpha or Key channels to do something specific. This is not a "film negative" plugin; this is a simple inversion.

Chapter 155

Resolve FX Film Emulation

These plugins are designed to emulate motion picture film characteristics for aesthetic and creative effects.

Camera Shake (Studio Version Only)

This effect replicates random camera motion for Horizontal and Vertical position, Rotation, and Zoom. A variety of parameters are provided to let you customize the quality of motion, from slow meandering drift to abrupt, jagged jerks and pops.

Main Controls

The primary controls governing how much camera shake is added.

- **Motion Scale and Speed Scale:** These sliders let you adjust the overall amplitude and speed of camera shake that's introduced to the image.
- **Motion Blur:** Lets you add simulated motion blur to the image being shaken, which can add a more realistic look to the motion. Motion blur is more visible on fast-moving motion, as DaVinci Resolve is simulating the effect of a motion picture camera's shutter speed on exposed subjects in motion.

Shake Levels

These controls let you adjust the intensity of camera shake.

- **Pan Amplitude:** Lets you set how much horizontal motion you want.
- **Tilt Amplitude:** This slider lets you choose how much vertical motion you want. These sliders are completely independent of one another.
- **Rotation Amplitude:** Lets you introduce rotational motion to the camera shake as well.
- **PTR Speed:** This slider lets you choose how fast the Pan, Tilt, and Rotation camera shake is.
- **Zoom Amplitude:** This slider lets you add zooming to the camera motion being created.
- **Zoom Speed:** This slider lets you choose how fast this random zooming should occur.
- **Zoom Type:** This pop-up menu lets you choose how to add zooming; you can choose Outward Only, Inward Only, or Outward and Inward. If you choose Inward Only, you don't have to worry about blanking appearing around the edges of the frame.

Shake Quality

These controls let you customize the type of shaking you want.

- **Motion Method:** This pop-up menu lets you choose from different ways of generating the motion this plugin introduces. You can choose from SINE, Rectified SINE, Rectified SINE (Invert), and Square Wave (good for popping or flickering motion).
- **Phase:** This slider lets you set the starting point of the camera shake you're creating, based on the Motion Method and Amplitude settings you've chosen.
- **Randomness Scale:** This slider lets you introduce irregularity to the Horizontal, Vertical, and Rotational motion of the camera shake. The greater this value, the more irregularity will be introduced.
- **Randomness Speed:** This slider lets you choose between smoothly erratic motion (at lower values) or more jagged motion (at higher values).
- **Pause Length:** This slider lets you adjust the frequency of intermittent pauses that break up the random motion added by this filter.
- **Pause Interval:** This slider lets you adjust the duration of intermittent pauses that break up the random motion added by this filter.
- **Pause Randomness:** This lets you add a degree of randomness to the intervals that happen.
- **Random Seed:** This slider lets you alter the value that sets what random values are being produced. Identical values result in identical randomness.

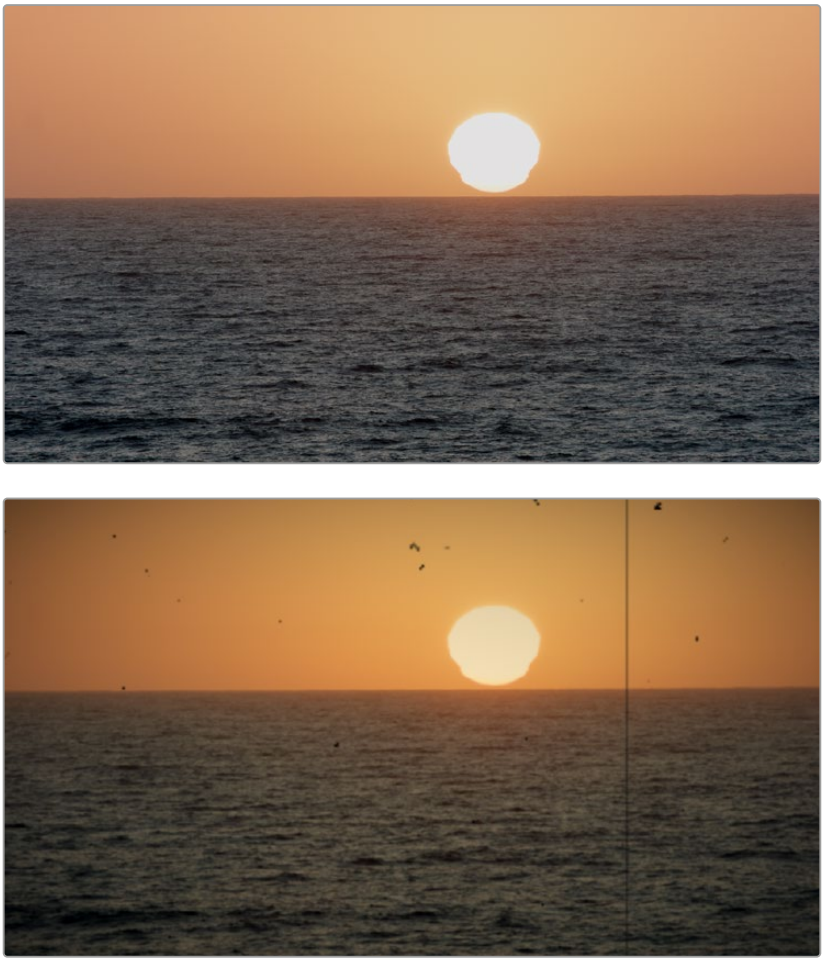
Blanking Handling

These controls let you determine what to do when camera shake causes blanking past the edge of the image.

- **Border Type:** This pop-up menu lets you choose how you want to fill the empty spaces at the edge that appear if the camera shake you create pushes the image out of the current frame size of your project. Four options let you choose to Replicate, Reflect, or Wrap-Around the image to fill the gap.
- **Zoom to Crop:** This slider lets you zoom in on the image to crop out unwanted blanking being introduced by the Camera Shake effect.

Film Damage

Found in the Resolve FX Texture category. After you've used the new Resolve FX Revival plugins to fix damage in archival footage, you can turn around and use the Film Damage plugin to make brand new digital clips look worn, dirty, and scratched instead. When used in conjunction with the Film Grain and Flicker Addition plugins, you can convincingly recreate the feel of poorly kept vintage archival footage.



(Top) Original image, (Bottom) Result with Film Damage

Blur and Shift Controls

The three parameters at the top let you alter the foundation of the image to begin creating the look of an older film.

- **Film Blur:** Adds just a bit of targeted defocusing to knock the digital sharpness out of the image.
- **Temp Shift:** Defaults to warming the image just a bit to simulate the warmer bulb of a film projector, although you can use it to cool or warm the image in varying amounts.
- **Tint Shift:** Defaults to yellowing the image to simulate damage to the film dyes, but you could move the slider in the other direction to add a bit of magenta, simulating a different kind of dye failure.

Add Vignetting

These parameters simulate lens vignetting darkening the edges of the image.

- **Focal Factor:** Adjusts how far the vignetting extends into the image.
- **Geometry Factor:** Affects how dark the vignetting is and how pronounced the edges are.
- **Tilt Amount:** Affects how balanced the vignetting at the top of the image is versus the bottom of the image.
- **Tilt Angle:** Affects how balanced the vignetting left of the image is versus the right, but only when Tilt Amount is set to something other than 0.

Add Dirt

These parameters let you simulate dirt particles (not dust) that have adhered to the film. These are larger specks, although there's several ways you can customize these.

- **Dirt Color:** This control lets you choose what color you want the dirt particles to be (black simulates dirt on a print, while white simulates dirt on a negative).
- **Changing Dirt:** This checkbox lets you alternate between simulating temporally unstable dirt on the film (checkbox on) and dirt on the lens that doesn't move (checkbox off).
- **Dirt Density:** Lets you choose more or fewer dirt particles appearing over time.
- **Dirt Size:** Lets you choose the average size of dirt particles to appear.
- **Dirt Blur:** Lets you defocus the dirt, so it's not so sharp.
- **Dirt Seed:** Changes the random distribution of dirt when you change this value, but for any given value, the results for any given set of control adjustments remain consistent.

Add Scratch

Five sets of Add Scratch parameters let you add up to five scratches to the image, simulating something scratching the emulsion while the film played.

- **Scratch Color:** Lets you choose the color you want the scratch to be (scratches can be a variety of colors depending on the depth of the scratch, type of film, and method of printing).
- **Scratch Position:** Lets you adjust the scratch's horizontal position on the image.
- **Scratch Width and Scratch Strength:** Let you adjust the scratch's severity.
- **Scratch Blur:** Lets you defocus the scratch.
- **Moving Scratch:** This checkbox lets you choose whether the scratch is jittering around or not.
- **Moving Amplitude:** Determines how far the scratch moves.
- **Moving Speed:** Determines how fast the scratch moves.
- **Moving Randomness:** Determines how the scratch meanders about.
- **Flickering Speed:** Determines how much the scratch flickers lighter and darker in severity.

Film Grain (Studio Version Only)

Composites a procedurally generated layer of simulated “film grain” over the image. Individual simulated grains with falloff are generated to match the resolution of the project.

Main Controls

These controls let you quickly choose and apply a film grain effect.

- **Film Grain Presets:** This pop-up lets you quickly choose from among different 8mm, 16mm, and 35mm film grain effects.
- **Composite Type:** Lets you choose a composite mode with which to combine the image with the grain simulated by this plugin.
- **Opacity:** Lets you fade the Film Grain effect against the original image.
- **Grain Only:** This checkbox lets you see just the grain layer that you’re creating, so you can evaluate its look prior to it being composited into the image.
- **Freeze:** Stops the motion of the grain animation, allowing you to use the effect for a still image or freeze frame.

Grain Params

The Grain Params group lets you adjust the quality of the grain.

- **Texture:** Larger values create more separation between the grains generated by this plugin, while smaller values bunch them up closer together to create denser grain patterns.
- **Grain Size:** Larger values zoom into the individual simulated grains generated by this plugin, while smaller values zoom out.
- **Grain Aspect Ratio:** Lets you adjust the aspect ratio of the grains.
- **Grain Strength:** Adjusts the contrast of the simulated grain layer. Higher values produce more contrast, lower values less.
- **Offset:** Lightens or darkens the entire simulated grain layer. The practical effect is that lower values emphasize lighter grains, while higher values emphasize darker grains.
- **Symmetry:** An asymmetrical contrast adjustment. Lower values darken the lighter grains, while higher values brighten the darker grains.
- **Softness:** Lets you blur the grain layer to create even softer transitions from one grain to another.
- **Saturation:** Lets you make the grain more or less colorful. At a value of 0, grain is monochrome.

Advanced Controls

In the Advanced Controls, the Red, Green, and Blue sliders control the color of the grain. The Shadow, Midtone, and Highlight Gain controls let you adjust the amount of grain that’s composited into each of these tonal regions of the image. When the Optimized Mode checkbox is turned on (the default), performance should improve substantially. Turning on the Animate on Every Refresh checkbox will animate the grain as you adjust the sliders, allowing you a better idea of how the grain pattern will look in motion.

Film Look Creator (Studio Version Only)

The Film Look Creator gives you the ability to easily alter both the color and physical properties of an image to mimic motion picture film stock in a single Resolve effect. This effect is not focused on emulating a specific manufacturer's film stock, rather it creates a base "Blackmagic" film look that can be manipulated in a variety of creative ways. The Film Look Creator alters contrast, saturation, hue, and exposure of an image. It also includes the tools you want to have for film emulation including halation emulation, film gate, flicker, weave, vignetting, bloom, and more.

The original video (Top), and the Film Look Creator Bleach Bypass Super 16mm version (Bottom)

Many of the components of the Film Look Creator have specific counterparts in the Resolve FX library. However, the Film Look Creator combines these film look tools into a single Resolve effect with a greatly simplified tool set. If you ever find you need more control over an aspect of the look, you can always disable the effect's module and use a dedicated Resolve Effect in the node tree instead.

When this effect is applied, an underlying Blackmagic film look is automatically set first. This film look is driven by over 60 parameters that you get with the plugin active (and all effects off). These parameters are fine tuned and "baked in" to the Blackmagic film stock. But while these can't be adjusted, there are additional controls on the top area of the plugin that you can use to refine and create unique looks.

The Film Look Creator is designed for scene referred workflows and will work with any camera source and output display. When using either Resolve Color Management or ACES, this happens

automatically because the plugin uses the timeline color space for input and output by default. The plugin works for manually display referred timelines (such as DaVinci YRGB) as well, but then the user must manually choose the transform of the source footage and choose the display transform, which you can do within the plugin in the Color Space Overrides section.

NOTE: Film Look Creator works best with video that fills the entire frame. Effects like Halation and Film Gate may give unexpected results with video that is smaller than the frame size. If necessary, you can fill the frame using the Sizing controls, or in Project Settings > Image Scaling > Input/Output Scaling select "Scale Full Frame with Crop" rather than the default "Scale entire image to fit."

Main Controls

These controls create the foundation of this effect.

- **Presets:** Automatically sets all controls for a desired preset look. "Clean Slate" does not apply the underlying Blackmagic Film Look and gives a clean image to work with. "Default No Effects" turns on the Blackmagic Film Look but disables all the additional effects below.
- **Color Blend:** Allows mixing the underlying color look and any changes made to other color settings and split tone controls.
- **Effects Blend:** The master control to adjust the strength of the spatial effects below. 0% is the effects completely off, and 100% is the full output of the Film Look Creator.
- **3D LUT Compatible:** Checking this box will remove spatial effect options which aren't represented in a 3D LUT. This allows you to export your custom film look to other programs and camera hardware via a LUT.

Color Space Overrides

These controls allow you to change the input and output gammas and color spaces of the effect if you need to manually configure them for a display referred workflow. Please note that no tone mapping is applied if you change these. The default is "Use timeline," which will match the color spaces you've selected in the Color Management section of the Project Settings.

- **Input Color Space:** Sets the input color space; choose one from the drop-down menu.
- **Input Gamma:** Sets the input gamma; choose one from the drop-down menu.
- **Output Color Space:** Sets the output color space; choose one from the drop-down menu.
- **Output Gamma:** Sets the output gamma; choose one from the drop-down menu.
- **Output White Point:** Sets the display white point. For creative purposes, you can choose one from the drop-down menu. D65 is the default white point.

Film Look

These controls allow you to adjust the overall parameters of the base film look.

- **Film Look Blend:** Adjusts the strength of the initial default base film look, before other parameters are adjusted.
- **Skin Bias:** Adjusts the skin tones of the film look. Negative values provide warm, darker, and more saturated skin tones, while positive values provide brighter, rosier, and less saturated skin tones.

Color Settings

These controls allow you to change the color information for the film look. These effects will be passed in a 3D LUT.

Exposure: A photometric control that adjusts the exposure in stops (+/- 5).

Contrast: Adjusts the overall S-curve transfer function to add or remove contrast from the shot.

Highlights: Adjusts the roll-off at the top of the S-curve, allowing you to reign in or expand the brightest areas of the shot.

Fade: Adjusts the roll-off at the bottom of the S-curve, allowing you to reign in or expand the darkest areas of the shot.

White Balance: This control uses chromatic adaptation to mimic what the source footage might look like if it were shot under different lighting conditions. Adjusted in degrees Kelvin.

Tint: Lets you adjust the green/magenta balance of the clip for balancing footage shot under limited spectrum lighting such as fluorescent, or sodium vapor streetlights.

Skin Bias: Lets you adjust the skin tones of the image. From -1 (warmer, darker, more saturated) to +1 (rosy, brighter, and less saturated). This can also be useful if you may, for example, push tint in one direction, and then use Skin Bias to balance out the image.

Subtractive Sat: Allows adjusting overall image saturation in a way that more closely resembles a subtractive method.

Richness: Affects already more saturated areas, applying subtractive saturation to just those regions. Can be useful for adding depth and richness, or pulling back a bit on more saturated areas.

Bleach Bypass: Simulates this well-known look by adding a desaturated, higher contrast version of the image onto itself.

Split Tone

These controls add color to shadows and highlights using an opposing hue angle. For example, adding orange to the highlights, and teal to the shadows to get a more modern cinematic look. These effects will be passed in a 3D LUT.

- **Enable Split Tone:** Turns this effect on or off.
- **Amount:** The intensity of the split tone. This value must be greater than 0 to see an effect.
- **Hue Angle:** This slider adjusts what complimentary hues are applied to the shadows and highlights.
- **Pivot:** This control sets where the hue transition occurs in luma. Set to its extreme of 0.000 or 1.0000, the pivot lets you apply a single tint to the shadows or highlight.

Vignette

These controls are simplified window for adding a vignette to the shot. For more detailed control you could disable this setting and use the Vignette effect instead.

- **Enable Vignette:** Turns the vignette on or off.
- **Amount:** Sets the intensity of the darkened areas of the vignette.
- **Size:** Sets how much the vignette reaches into the frame.

Halation

These controls are a simplified way of adding soft glows to the edges of the subjects in your frame, to mimic this characteristic of motion picture film. If you want more control, you can disable this setting and use the Halation effect instead.

- **Enable Halation:** Turns the Halation effect on or off.
- **Highlights Only:** Limits the Halation effect only to the edges of highlights.
- **Amount:** Lets you set the intensity of the halation.
- **Radius:** Lets you set the spread size of the glow from the edges.
- **Saturation:** Lets you adjust the color intensity of the halation.
- **Hue:** Lets you tint the glow a selected color.

Bloom

These controls lets you introduce a subtle glow around the edges of highlights.

- **Enable Bloom:** Turns the Bloom effect on or off.
- **Amount:** Lets you set the intensity of the bloom.
- **Radius:** Lets you set the spread size of the bloom from the edges.

Grain

These controls are a simplified set of tools to emulate the grain patterns found on motion picture film. For more detailed control you can disable this setting and use the Film Grain effect instead.

- **Enable Grain:** Turns the grain pattern on or off.
- **Preset:** Provides some starting points for grain, based on film stock standards.
- **Amount:** Determines the amount of grain in the image.
- **Size:** Determines the size of the grain in the image.
- **Softness:** Determines how crisp the individual grains are.
- **Saturation:** Adds color to the grain. 0 is monochromatic.
- **Image Defocus:** Affects the overall resolution of the image, defocusing more as you reduce the control towards 0. At 1.000 the resolution is untouched. This control does not affect the grain.

Flicker

These controls add a gentle pulse to the image exposure, mimicking the flicker of motion picture projection. For more detailed controls you can disable this setting and use the Flicker Addition effect instead.

- **Enable Flicker:** Turns the Flicker effect on or off.
- **Amount:** Sets how much flicker to add to the image. Low settings will be barely visible, while high settings can be useful for more extreme looks like the Nostalgic preset.
- **Rate:** The rate at which the flicker pulses.

Gate Weave

These controls mimic the slight horizontal and vertical shift of the image as the film is mechanically pulled through the camera's gate.

- **Enable Gate Weave:** Turns the Gate Weave on or off.
- **Amount:** Determines the amount of motion to the weave.
- **Rate:** The rate at which the weave moves.

Film Gate

These controls will add blanking to the edges of the image that mimic film projection or telecine alignment controls.

- **Enable Film Gate:** Turns the Film Gate on or off.
- **Preset:** Select an aspect ratio from different common film standards.
- **Ratio H/V:** You can set a custom ratio for the image here.
- **Enable Curvature:** Turning this on slightly rounds the corners of the image to mimic how the shape of an actual film frame is exposed.
- **Padding:** This will zoom the image in and out of the blanking, allowing you to see the entire exposed "frame" of film if desired. Similar to a telecine control.

NOTE: It is possible to get unexpected results using Film Gate with video that is not scaled to fill the entire frame. If this is the case, use the sizing controls to fill the frame with your image first.

Flicker Addition

Why remove flicker with the Resolve FX Flicker Removal plugin when you can add it instead? The Flicker Addition plugin adds rapidly animated exposure changes to make the image appear to flicker, creating animated effects that would be difficult to keyframe manually. When applied to an image in different ways, this plugin can be used to simulate torchlight, firelight, light fixtures with old ballasts or frayed wiring, or any temporally unstable light source. For example, you could key only the highlights of a night-time image and use Flicker Addition to affect those isolated highlights.

Two groups of controls let you control the quality of this flickering.

Main Controls

These controls let you choose how to apply the flicker and its overall speed and intensity.

- **Flicker Type:** This pop-up menu lets you apply the flicker as a Lift, Gamma, Gain, Vignette, or Alpha adjustment.
- **Range slider:** This lets you set how widely the flickering will vary.
- **Speed:** This lets you adjust how quickly the flickering is animated.
- **Smoothness:** This slider lets you adjust the temporal quality of the flickering, whether it changes abruptly from one value to another (at lower settings) or whether it makes more continuous transitions from one value to another (at higher settings).
- **Flicker R, G, B Channels:** Three checkboxes let you choose which color channels are affected by this flickering.

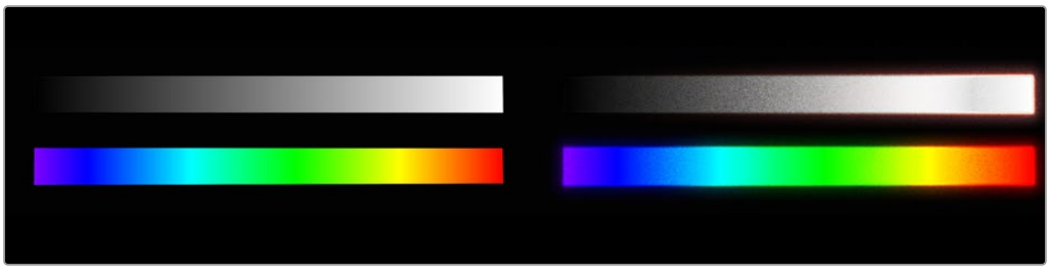
Flicker Quality

These controls let you adjust the details of how the flickering animates.

- **Randomness Scale:** This slider lets you introduce irregularity to the Horizontal, Vertical, and Rotational motion of the camera shake. The greater this value, the more irregularity will be introduced.
- **Pause Length:** This slider lets you adjust the frequency of intermittent pauses that break up the random motion added by this filter.
- **Pause Interval:** This slider lets you adjust the duration of intermittent pauses that break up the random motion added by this filter.
- **Pause Randomness:** This lets you add a degree of randomness to the intervals that happen.
- **Random Seed:** This slider lets you alter the value that sets what random values are being produced. Identical values result in identical randomness.

Halation (Studio Version Only)

An effect that mimics the subtile light scatters, reflections, and analog blooms of light reflecting back through the dye layers of motion picture film. This usually presents itself as a fine red/orange tinted glow around high contrast bright regions, like lights or reflections. Halation can also be caused by light reflections within processing and development equipment, or in the camera itself. These minor flaws can add a subtle organic and analog look to digital files.



The Halation effect can add an organic and analog look to your digital files. Original (L), Halation (R).

There are a variety of tools and controls to give you fine detail on exactly how the halation will appear.

The shot before the Halation effect

The Halation effect on the same image; note the
halation in the water reflections and the woman in the white t-shirt.

Processing Color Space

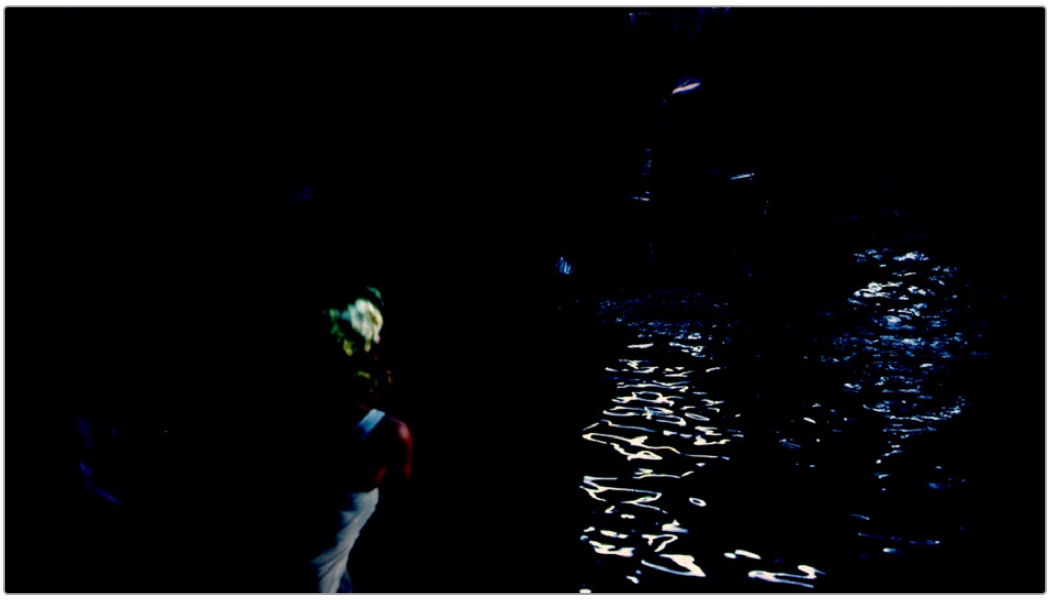
Lets you chose the color space for the Halation effect. The default is the same as the current timeline.

Isolation

The Isolation controls define which regions of your clips will form halation halos.

- **Threshold:** The level low clip level for the Halation effect.
- **Normalization:** The high clip level for the Halation effect.

- **Film Saturation Level:** The level above which all color is suppressed and saturated to white. Especially useful in HDR workflows, so the resulting Halation effects are visible at HDR brightness levels.
- **View Isolated Regions:** Shows only the regions isolated for generating the Halation effect.



The View Isolated Regions checkbox shows you the areas that will be affected by the halation.

Dye Layer Reflections

The Dye Layer Reflections controls give you the ability to fine tune the physical characteristics of the halation glow.

- **Strength:** Controls the brightness of the reflection.
- **Gamma:** Controls the how the glow spreads out.
- **Saturation:** Controls the intensity of the color of the glow.
- **Spread:** Defines the extent of the dye reflection.
- **Fine Tune Relative Spread:** Checking this box allows you to manually adjust the red, green, and blue reflection distances.

Secondary Glow

The Secondary Glow controls add additional halation characteristics.

- **Strength:** Controls the brightness of the secondary glow.
- **Gamma:** Controls how the glow spreads out.
- **Spread:** Defines the extent of the glow around bright detail.
- **Filter:** Limits the color of the glow in the selected color.

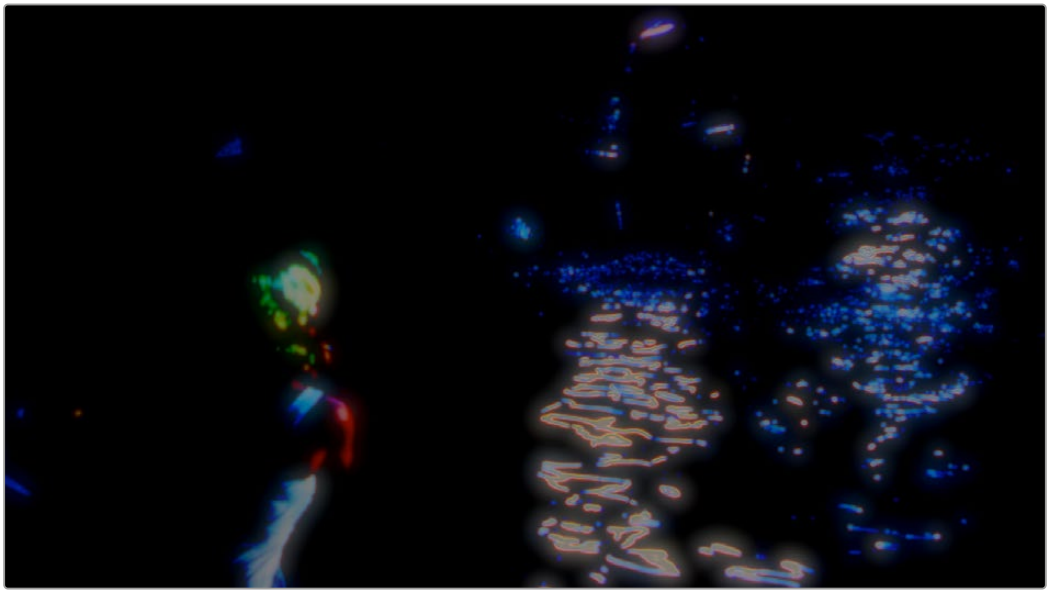
Basic Grain

These controls are a subset of the Film Grain effect for quick grain settings. If you prefer, you can add an instance of the full Film Grain effect after the Halation effect on the same node for greater detail.

- **Append Gain internally:** Turns on the simplified grain control.
- **Strength:** Adds grain to the halation layer.
- **Size:** Controls the size of the grains in the halation layer.
- **Softness:** Softens the grain texture.
- **Saturation:** Applies saturation on the grain.

Global Adjustments

- **View Glow Alone:** This checkbox shows the Halation effect alone before it's added to the frame. This is a useful setting to turn on when modifying any of the above tools.



The View Glow Alone checkbox shows you only the Halation effect in isolation and not blended with the underlying image.

- **Reduce Highlights:** Reduces the effect where it will brighten the scene without contributing to the halo. This essentially confines the halo to the edges of a region without blowing out the region itself.
- **Aspect Ratio:** Stretch or squeeze the glow and grain horizontally for anamorphic projects.
- **Detail Loss:** Removes sharp detail that the film stock should not have captured by defocusing the image under the effect.

Vignette

A plugin with two modes for creating vignette effects of different kinds.

- Basic mode gives you Size, Anamorphism, and Softness controls for quickly creating a traditional lens vignetting effect to darken the edges of the frame. A Color control lets you tint the vignette.
- Advanced mode adds Border Shape, Rotation, Center, Transparency, and Composite Type controls for customizing this vignetting effect even more specifically.

Chapter 156

Resolve FX Generate

These plugins generate imagery that can be used within grades and composites in different ways.

Contents

Color Generator 3342
Color Palette (Studio Version Only) 3342
Grid 3342

Color Generator

Generates a single color using a color picker or eyedropper control. Useful in conjunction with a layer node's ability to mix a color with an image using different composite modes.

- **Color picker:** You can click the color picker and use the resulting color controls to choose a color to be generated.
- **Eyedropper:** You can also click the eyedropper to sample a color from the image in the Viewer; the eyedropper always samples the image from the input of the current node, regardless of how the current image looks.

Color Palette (Studio Version Only)

More of an analysis tool than a creative effect, this plugin displays the dominant colors of each frame.

- **Display Mode:** A pop-up that provides four different options.

  Color Palette: This displays the most dominant colors in the image as rectangular swatches along the bottom (8 colors is the default), and the eight most dominant colors in each of the three main zones of image tonality (shadow, midtone, highlight) are displayed as smaller rectangular patches just above. This lets you see, at a glance, the color palette of any given shot, and this can be output for intrepid art directors who find it useful.

  Shadow Region, Midtone Region, or Highlight Region: Displays a visual preview of which parts of the image fall into which regions (as currently defined by the Shadow and Highlight Threshold sliders). These previews are displayed with the current tonal region appearing saturated and all other parts of the image appearing black.

- **Number of Colors:** Defines the number of isolated colors. This can be set to display anywhere from 8 to 24 patches.
- **Shadow and Highlight Threshold:** The definition of where shadows, midtones, and highlights end and begin is controlled by the Shadow and Highlight Threshold sliders.

Grid

As the name implies, this plugin generates a grid overlay on your image. Not a creative effect, but a useful measuring tool for your images.

- **General:** These controls let you adjust the overall density and orientation of the grid.

  Row Cells and Column Cells: These sliders let you choose how many cells to divide the grid into, both vertically and horizontally.

  Major Line Spacing: Sets how many grid squares will make up a thicker major line on the grid. A value of zero turns this function off.

- **Line Properties:** These controls let you control the properties of the grid lines themselves.

  Line Color: This color picker control and accompanying eyedropper let you choose a color with which to draw the grid.

  Individual Hor. Line Width and Ver. Line Width: These sliders let you adjust the thickness of all horizontal or all vertical lines.

  Major Line Width: Lets you choose how thick to make the major lines.

  Pan, Tilt, Zoom, Rotate, Width, Height, ShearX, ShearY, Pitch, and Yaw: These controls let you transform the grid to serve whatever purpose is necessary.

Chapter 157

Resolve FX Key

DaVinci Resolve includes several Resolve FX dedicated to compositing and keying tasks that are applied directly on the Timeline.

3D Keyer

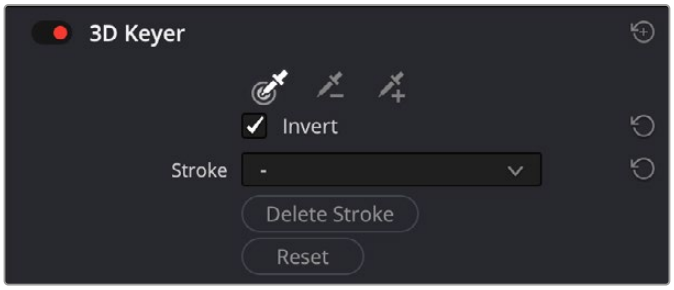
Based on the 3D Qualifier in the Color page, the 3D Keyer Resolve FX offers a fast, simple way of pulling a key to isolate a range of color in the image by dragging your mouse pointer over the parts of the image you want to key. Each time you drag over the image to add or subtract from the cloud of values, you're carving out of a three-dimensional representation of all available colors; this is viewable in the tools Key Map box and is what gives the 3D Keyer its name.

TIP: If you're looking to isolate a range of luma values in the image, the HSL or Luma keyer will give you more control.

The 3D Keyer is a good one to start with if you're trying to key a blue screen or green screen background. Its interface of dragging the mouse pointer over the screen color you want to remove, with live feedback, gives precise control. The 3D Keyer's greatest strength is the speed with which you can sample areas of the picture to extract from the final key. However, this can also be a weakness if your initial samples aren't giving you satisfactory results because, unlike the Delta Keyer in the Fusion page, there aren't many ways to fine-tune the key as it's being generated. On the other hand, for well-lit subjects you want to key, two or three samples is all you need. Small numbers of long strokes will generally give better results in consistently selecting a range of similar colors, like a broad brush. Conversely, five to ten short strokes act like a fine brush and will only select a very narrow range of color that you've specified.

Selection Range Controls

The Selection Range buttons in the Inspector let you define a key by sampling pixels in the Viewer with the mouse pointer.



The 3D Keyer Selection Range controls

- **Picker:** Chooses the initial color to qualify. Longer strokes will tend to give you a better key. In the Edit page, the Timeline Viewer Overlay must be set to Open FX.
- **Picker -:** Lets you choose an additional color to exclude from the current qualification; also available by holding down the Option key.
- **Picker +:** Choses an additional color region to add to the current qualification.
- **Invert:** Inverts the current key; qualified areas are then unqualified and vice versa.
- **Stroke:** Displays the list of picked (+) and unpicked (-) colors, along with their respective RGB values.
- **Delete Stroke:** Deletes the current stroke selected in the Stroke drop-down menu.
- **Reset:** Deletes all strokes and resets the 3D Keyer to its default state.

Behavior Options

These controls adjust the fundamental parameters and modes of the 3D Keyer.

- **Colorspace:** This drop-down menu lets you choose whether you're sampling colors in YUV, HSL, HSP, or LAB colorspaces. YUV is the default, but if you find you're not getting satisfactory results, you can choose another colorspace from the drop-down menu to see if that works any better. These have various theoretical differences but the best choice always depends on the task.
- **Soft:** Provides a softer edge to the key that is more forgiving of Chroma and Luma adjustments. The more gentle drop-off is suitable for situations like subtle light changes across a face. Use the Shadow/Midtone/Highlight Matte Finesse controls in conjunction with this mode to fine tune the result.
- **Flat:** The default mode. Each color selected is 100% keyed, and adjustments are made for small color variations. This is the recommended mode for chroma keying a green or blue screen. Additionally, turning up the Pre-Filter setting in the Matte Finesse controls can make for a smoother, flatter key.
- **Tight:** Only keys the exact color range picked and does not apply any softening based on color ranges. Single pixel sharpness levels are expected. This can be used for difficult keying jobs, requiring adjusting the filter and softness manually in the Matte Finesse controls.
- **Luma:** Functions similar to the Tight setting but ignores all chroma data, letting you key by brightness level and not color.
- **Despill:** If you're using the 3D qualifier to pull a blue or green screen key to create transparency, this slider lets you adjust color correction that eliminates blue or green spill from the image, while retaining the image's original color.

Usage Options

The Key Map, shown in the upper left, showing a qualifier that attempts to select the sand in the background (blue lines), while deselecting the pirate's hats (red lines)

These settings control the user feedback tools from the 3D Keyer in the Viewer. In the Edit page, the Timeline Viewer Overlay must be set to Open FX.

- **Show Paths:** A checkbox that lets you turn on and off the visibility of the lines you're drawing to sample the image. Turning lines off does not affect the key.

- **Smart Show Paths:** With this checkbox enabled, the lines will only be visible as they are being drawn, and disappear when the mouse button is released.
- **Auto-B/W Highlight:** With this checkbox enabled, the Viewer automatically switches to Highlight B/W mode while drawing a line, to better show you the resulting key in real time. When the mouse button is released, the Viewer switches back to its original viewing mode.
- **Show Key Map:** Check this box to show the Key Map in the Viewer. The Key Map is composed of the Color Space box, and the Brightness Range. The Color Space box is laid out roughly in the same manner as the Color Wheels, with primary colors laid out around its edge. The exact colors and layout is determined by the Color Space that you choose in the 3D Keyer. The Brightness Range is represented as a bar underneath the Color Space, with left being black and right being white. Inside the Color Space and Brightness Range lie the individual colors that you chose with the pickers in the Strokes List.
- **Key Map Zoom:** Controls the zoom level of the Key Map, so you can see finer detail, if necessary.

Key Adjustments

This set of tools allows you to manually adjust the generation of the key from the sampled colors. Feedback from these tools can be seen in the Key Map, if enabled.

- **Chroma Tolerance:** Click and drag left and right to expand or contract the range of colors selected by the key.
- **Chroma Softness:** Click and drag left and right to change the sensitivity to similar colors selected by the key. This determines whether the key is a hard cutoff or a soft selection of similar colors.
- **Adaptive Chroma Softness:** Checking this box allows the keyer to operate consistently in both highly saturated and desaturated regions of the image at the same time. The majority of the time you will want to leave this on. The exception is if you are having difficulty in manually adjusting chroma softness in Soft or Flat mode, then turning Adaptive Chroma Softness off will give you more range to work with. Adaptive Chroma Softness is automatically disabled in Tight and Luma modes as it is contrary to those mode's functionality.
- **Chroma Tilt:** Moves your selected color region within the color space, changing its chroma based on its vertical position.
- **Chroma Shift:** Moves your selected color region within the color space, changing its chroma based on its horizontal position.
- **Chroma Rotate:** Moves your selected color region within the color space, changing its tint and temperature based on its rotation around the central origin point.
- **Luma Low:** Expands or contracts the dark areas of the key in the brightness range.
- **Luma High:** Expands or contracts the bright areas of the key in the brightness range.
- **Low Softness:** Controls how well defined the low end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.
- **High Softness:** Controls how well defined the high end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

TIP: All of the parameters above are key-framable, allowing you to animate the key over time. For example, you may have qualified a shirt where the actor walks through different colored light in a scene. By key framing the parameters above, you can hold the same key on the shirt as it changes colors over time.

Matte Finesse

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noise can sometimes be fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, modifying the key using the frame's content.

- **Pre Filter:** This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.
- **Clean Black:** Clean Black is a specialized operation that eliminates noise seen as white speckling in the black area of a key. Raising Clean Black lets you "fill holes" in the background portion of a key and erode translucent edges.
- **Clean White:** Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that includes areas of the image you're isolating and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you "fill holes" in the foreground portion of a key and grow translucent edges.
- **Black Clip:** Raising Black Clip applies a "lift" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.
- **White Clip:** Lowering White Clip applies a "gain" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.
- **Blur Radius:** In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you're keying, with the result being a visible "halo" around your subject, depending on the adjustment you're making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.
- **In/Out Ratio:** Using In/Out Ratio can help eliminate fringing. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.
- **Morph Operation:** You can choose Shrink or Grow to dilate or erode the edges of the matte, or you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.
- **Morph Radius:** Adjusts how much to shrink, grow, open, or close the key.
- **Denoise:** Provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.
- **Shadow:** Adjusts key strength based on the darker parts of the original image.
- **Midtone:** Adjusts key strength based on the midtones of the original image.
- **Highlight:** Adjusts key strength based on the brighter parts of the original image.
- **Post Filter:** Performs a final clean-up of the key, using the original image for reference; useful for bringing back some fine detail in sharp edges or hair.

Garbage Matte

These controls let you crop out other unwanted things in the frame, such as lighting fixtures, boom microphones, tracking patches, etc.

- **Matte Shape:** You can choose either a Rectangle or Ellipse with which to crop around the subject you're keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.
- **Edge Softness:** Lets you soften the edges. Defaults to 50; the range is 0 (no softening) to 100 (maximum softening).
- **Invert:** Inverts the garbage matte.
- **Center X and Y:** Lets you adjust and keyframe the position of a garbage matte.
- **Bounding Width and Height:** Lets you adjust the width and height of the garbage matte.
- **Rotation:** Lets you adjust the angle of the garbage matte.

Output

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

- **Output:** This menu offers three options for which channels are output from the effect.

  Alpha Highlight: Displays the transparent part of an Alpha channel as gray and the solid part of an alpha channel in full color.

  Alpha Highlight B/W: Displays the black and white Alpha channel, which is often helpful when sampling additional areas to key.

  Final Composite: The keyed image is displayed composited over any video track below it.

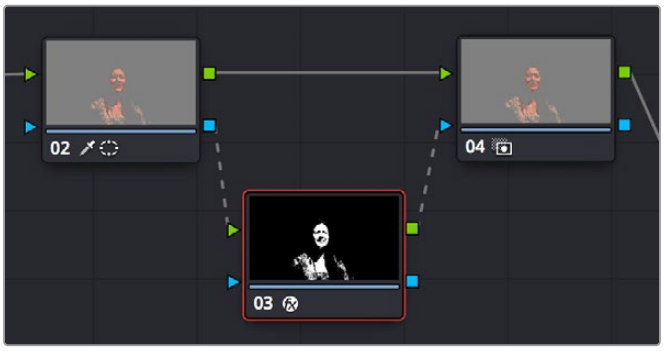
- **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plugins; this checkbox determines if the alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only (Blank Alpha) from the Output menu.

To use the 3D Keyer in the Edit page:

1. Apply the 3D Keyer to a green screen or blue screen clip that's on a higher track than the background.
2. In the Inspector, enable the Show Paths checkbox to view the sampled areas once you begin.
3. From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer, choose Open FX Overlays.
4. In the Viewer, click and drag to draw a sampling stroke across the screen color you want to remove.
5. The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.
6. If necessary, you can add or subtract areas from the screen color selection using the add/subtract Color range controls. Alternatively, with the default Sample eyedropper selected, you can hold down Shift to add to the screen color selection or hold down the Option key to remove from the screen color selection.

Alpha Matte Shrink and Grow (Studio Version Only)

This filter lets you refine the edges of alpha and key mattes in a variety of ways, shrinking and growing the edges, and opening and closing holes that appear within a matte. In the Color page, this filter can be applied to Qualifier or Window keys that have been routed to the RGB input of a corrector node, for adjustment and refinement, before connecting the result to the key input of a subsequent node for use isolating an adjustment.



Applying the Alpha Matte Shrink and Grow filter to a key matte that's fed to the RGB input of a separate node

- **Morph Operation:** A drop-down menu lets you choose how you want to modify the Alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes within the key to clean up a ragged matte.
- **Shape:** A drop-down menu lets you choose how corners and angles in the edges of the key are handled when you grow or shrink it. Circle is the default, and results in even expansion around the surface of the key that eventually averages all angles into a circular shape if you use extreme Radius settings. Square averages all angles into a more rectangular shape if you use extreme Radius settings. Diamond averages all angles into a diamond shape if you use extreme Radius settings.
- **Radius:** A slider adjusts how much to Shrink, Grow, Open, or Close the key.
- **Process:** Lets you select specific channels to apply the Morph Operation to. Options are RGB (Blank Alpha), Alpha (RGB Unaffected), and RGB + Alpha.

  Preview Alpha: Checking this box lets you quickly see the Alpha channel that will be output from the node.

- **Manual Iteration Control:** Checking this box gives you direct control on how the operators are applied.

  Operator Radius: A slider that controls the size of the operator.

  Repeat Operation: A slider alters the effect of the Operator Radius setting to create more extreme adjustments.

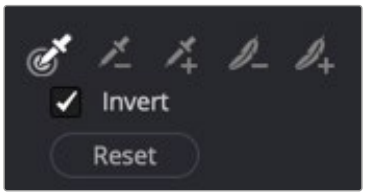
HSL Keyer

Based on the HSL Qualifier in the Color page, the HSL Keyer Resolve FX is a general-purpose keyer that uses three color components, hue, saturation, and luma, to define a key. The HSL Keyer also gives you the option of disabling color components that you don't want to contribute to the final key. You can pull a saturation-only key, or a hue-only key, for instances where choosing only individual components gives a better result.

The most straightforward way to use any keyer is to sample the image in the Viewer with no changes to the settings. When you sample one or more pixels, the hue, saturation, and luma values are analyzed and set different ranges. There are several eyedropper controls available to sample color and soften the selection.

Selection Range Controls

The Selection Range buttons in the Inspector let you define a key by sampling and softening pixels in the Viewer with the mouse pointer.

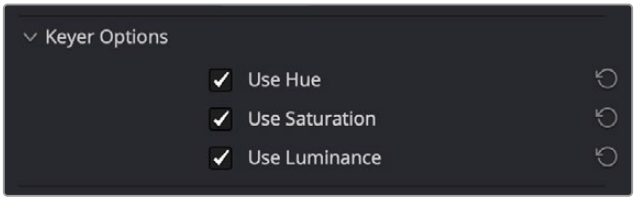


HSL Keyer Color Range controls

- **Sample Eyedropper:** This tool selects the colors to use as the range of qualification by clicking and dragging over the image in the Viewer. Clicking it again clears the previous selection. Generally, you will get better results using long drags instead of short ones.
- **Add/Subtract Color Range:** These two controls let you add areas of the image to, or subtract them from, the currently selected inner range of values that define the core of the key. Like the other sampling controls, you can drag over a range of color.
- **Add/Subtract Softness:** These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Like the other sampling controls, you can drag over a range of color.
- **Invert:** Inverts the sampled color to become opaque, and areas not sampled become transparent.
- **Reset:** Resets all the sampled colors while retaining the general control settings.

Keyer Options

One of the HSL Keyer's strengths is that you can enable or disable each of the three HSL components using the Hue, Sat, and Lum checkboxes. This lets you ignore specific color components while focusing on others that may be more important. For example, if you're trying to key the saturated parts of an image, regardless of the hue or brightness, you can turn off Hue and Lum so that only Sat is used to sample it.



HSL Keyer options

Matte Finesse

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noise can sometimes be fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, modifying the key using the frame's content.

- **Pre Filter:** This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.
- **Clean Black:** Clean Black is a specialized operation that eliminates noise seen as white speckling in the black area of a key. Raising Clean Black lets you "fill holes" in the background portion of a key and erode translucent edges.
- **Clean White:** Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that includes areas of the image you're isolating and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you "fill holes" in the foreground portion of a key and grow translucent edges.
- **Black Clip:** Raising Black Clip applies a "lift" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.
- **White Clip:** Lowering White Clip applies a "gain" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.
- **Blur Radius:** In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you're keying, with the result being a visible "halo" around your subject, depending on the adjustment you're making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.
- **In/Out Ratio:** Using In/Out Ratio can help eliminate fringing. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.
- **Morph Operation:** You can choose Shrink or Grow to dilate or erode the edges of the matte, or you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.
- **Morph Radius:** Adjusts how much to shrink, grow, open, or close the key.
- **Denoise:** Provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.
- **Shadow:** Adjusts key strength based on the darker parts of the original image.
- **Midtone:** Adjusts key strength based on the midtones of the original image.
- **Highlight:** Adjusts key strength based on the brighter parts of the original image.
- **Post Filter:** Performs a final clean-up of the key, using the original image for reference; useful for bringing back some fine detail in sharp edges or hair.

Garbage Matte

These controls let you crop out other unwanted things in the frame, such as lighting fixtures, boom microphones, tracking patches, etc.

- **Matte Shape:** You can choose either a Rectangle or Ellipse with which to crop around the subject you're keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.
- **Edge Softness:** Lets you soften the edges. Defaults to 50; the range is 0 (no softening) to 100 (maximum softening).
- **Invert:** Inverts the garbage matte.
- **Center X and Y:** Lets you adjust and keyframe the position of a garbage matte.
- **Bounding Width and Height:** Lets you adjust the width and height of the garbage matte.
- **Rotation:** Lets you adjust the angle of the garbage matte.

Output

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

- **Output:** This menu offers three options for which channels are output from the effect.

  Alpha Highlight: Displays the transparent part of an Alpha channel as gray and the solid part of an alpha channel in full color.

  Alpha Highlight B/W: Displays the black and white Alpha channel, which is often helpful when sampling additional areas to key.

  Final Composite: The keyed image is displayed composited over any video track below it.

- **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plugins; this checkbox determines if the Alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only (Blank Alpha) from the Output menu.

To use the HSL Keyer in the Edit page:

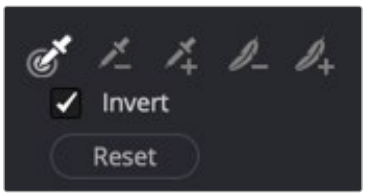
1. Apply the HSL Keyer to a clip on video track 2 or higher.
2. From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer choose Open FX Overlays.
3. Click and drag across the screen color you want to remove.
4. The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.
5. To add or subtract from the matte, click the plus or minus Color Range control, and click or drag across the portion of the keyed image.
6. To add softness to the outer range of the key you're creating, click the plus Softness control and then click or drag across the portion of the image you'd like to include as a soft edge.

Luma Keyer

Based on the Luma Qualifier in the Color page, the Luma Keyer pulls a key from the luma channel. It's identical to the HSL Keyer with H and S turned off. Although not often used by itself, the Luma Keyer can produce useful effects when used in conjunction with Composite modes.

Selection Range Controls

The Selection Range buttons in the Inspector let you define a key by sampling pixels in the Viewer with the mouse pointer.



Luma Keyer Selection Range controls

- **Sample Eyedropper:** The first control you use whenever sampling the image. It defines the initial range of the keyer; you must use this tool before any of the others. In the Edit page, the Timeline Viewer Overlay must be set to Open FX. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.
- **Add/Subtract Luma Range:** These two controls let you add areas of the image to, or subtract them from, the currently selected luma range that defines the core of the key. As with the eyedropper, you can click on single pixels, or drag over a range of color.
- **Add/Subtract Softness:** These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Like the other keying controls, you can click on single pixels, or drag over a range of color.
- **Invert:** Inverts the sampled luma range to become opaque, and areas not sampled become transparent.
- **Reset:** Resets the sampled luma range while retaining the Output control settings.

Matte Finesse

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noise can sometimes be fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, modifying the key using the frame's content.

- **Pre Filter:** This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.
- **Clean Black:** Clean Black is a specialized operation that eliminates noise seen as white speckling in the black area of a key. Raising Clean Black lets you "fill holes" in the background portion of a key and erode translucent edges.
- **Clean White:** Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that includes areas of the image you're isolating and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you "fill holes" in the foreground portion of a key and grow translucent edges.

- **Black Clip:** Raising Black Clip applies a “lift” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.
- **White Clip:** Lowering White Clip applies a “gain” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.
- **Blur Radius:** In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject, depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.
- **In/Out Ratio:** Using In/Out Ratio can help eliminate fringing. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.
- **Morph Operation:** You can choose Shrink or Grow to dilate or erode the edges of the matte, or you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.
- **Morph Radius:** Adjusts how much to shrink, grow, open, or close the key.
- **Denoise:** Provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.
- **Shadow:** Adjusts key strength based on the darker parts of the original image.
- **Midtone:** Adjusts key strength based on the midtones of the original image.
- **Highlight:** Adjusts key strength based on the brighter parts of the original image.
- **Post Filter:** Performs a final clean-up of the key, using the original image for reference; useful for bringing back some fine detail in sharp edges or hair.

Garbage Matte

These controls let you crop out other unwanted things in the frame, such as lighting fixtures, boom microphones, tracking patches, etc.

- **Matte Shape:** You can choose either a Rectangle or Ellipse with which to crop around the subject you’re keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.
- **Edge Softness:** Lets you soften the edges. Defaults to 50; the range is 0 (no softening) to 100 (maximum softening).
- **Invert:** Inverts the garbage matte.
- **Center X and Y:** Lets you adjust and keyframe the position of a garbage matte.
- **Bounding Width and Height:** Lets you adjust the width and height of the garbage matte.
- **Rotation:** Lets you adjust the angle of the garbage matte.

Output

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

- **Output:** This menu offers three options for which channels are output from the effect.

  Alpha Highlight: Displays the transparent part of an Alpha channel as gray and the solid part of an alpha channel in full color.

  Alpha Highlight B/W: Displays the black and white Alpha channel, which is often helpful when sampling additional areas to key.

  Final Composite: The keyed image is displayed composited over any video track below it.

- **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plugins; this checkbox determines if the Alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only (Blank Alpha) from the Output menu.

To use the Luma Keyer in the Edit page to key a subject:

1. Apply the Luma Keyer to a clip on video track 2 or higher.
2. From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer choose Open FX Overlays.
3. Either click a pixel in a bright or dark part of the image you want to key out, or click and drag across a range of pixels within that subject.
4. The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.
5. To add or subtract from the matte, click the plus or minus Luma Range buttons, and then click or drag across the portion of the keyed image.
6. To add softness to the outer range of the key you're creating, click the plus Softness button and then click or drag across the portion of the image you'd like to include as a soft edge.

Chapter 158

Resolve FX Light

The plugins in this category all replicate different optical and lighting effects. While most have been designed to quickly give you realistic results, all can be pushed harder to provide many artistic effects.

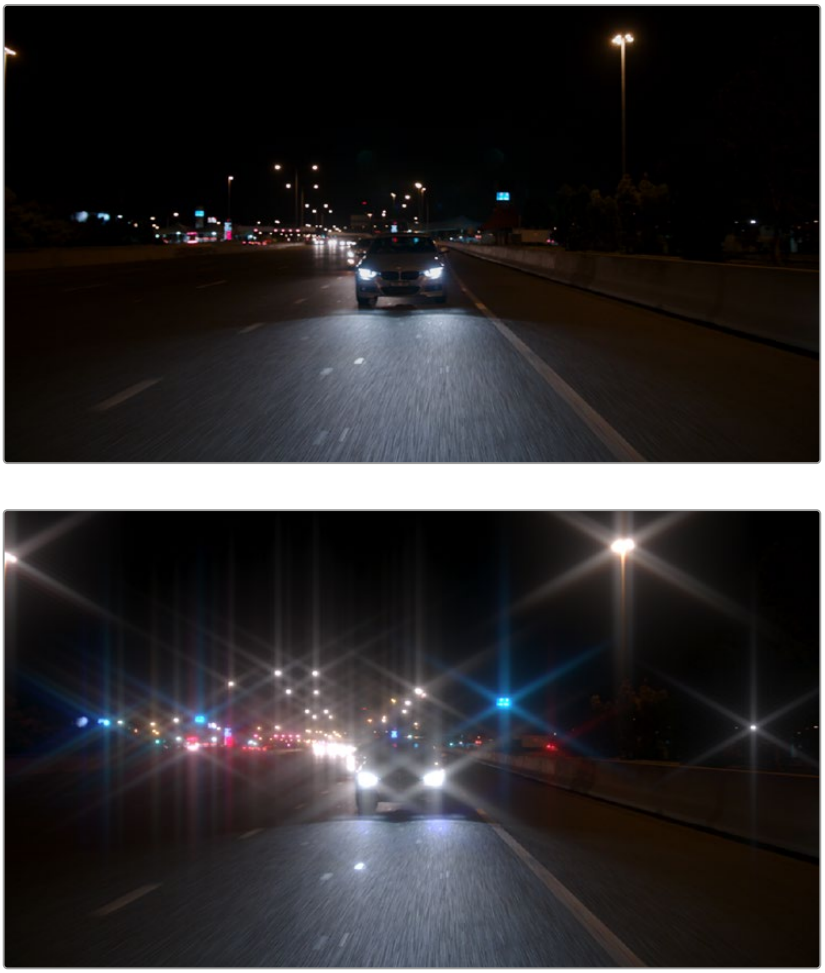
COLOR

Aperture Diffraction (Studio Version Only)

Found in the ResolveFX Light category, Aperture Diffraction models the starburst effect usually seen when shooting bright lights with small apertures, the physical cause of which is light-diffraction on the aperture blades of a lens. This plugin simulates this, with the result being automatically applied to scene highlights that you can isolate and refine, with customizable virtual apertures.

Small regions of brightness exhibit a star pattern glow, as seen in the following image.



(Top) Original image, (Bottom) Applying Aperture Diffraction

Large regions of brightness exhibit a more even glow with shaping and texture that look like a natural optical effect. It can be used to create a different type of glow effect with a more realistic look in some situations than the Glow plugin, though it's more processor intensive. In other situations, this plugin opens up many different stylistic possibilities for glowing effects.

(Top) Original image, (Bottom) Applying Aperture Diffraction

Output

These controls let you choose what image is output by this plugin.

- **Select Output:** Lets you preview the image with different stages of the Aperture Diffraction effect applied.

  Isolated Source: Used to help when adjusting the Isolation controls.

  Preview Aperture: Used to help when adjusting the Aperture controls.

  Preview Diffraction Pattern: Shows you the resulting diffraction pattern based on the aperture control settings.

  Diffraction Patterns Alone: Shows you the glow effect that will be applied to the image by itself.

  Final Composite: Shows you the final output of the effect.

- **Alpha Masks Light Sources:** Check this box to use the input Alpha channel to exclude sources in those areas from casting light rays.
- **Alpha Limits Effect:** Check this box to use the input Alpha channel for compositing purposes. Unchecking means the input Alpha is ignored.
- **Quality:** Lets you choose a quality setting to trade off between quality and speed. Choices are Full, Half (Faster), Quarter (Fast). High quality gives diffraction of finer detail, but otherwise does not change the effect. If you have no small light point sources, you can safely use half or quarter qualities with no reduction in image quality.

Isolation Controls

The Isolation controls let you choose which highlights in the scene generate visible glow and patterns. The effect of these controls can be directly monitored by setting Select Output to Isolated Source.

- **Color Mode:** A pop-up menu that lets you either choose to keep the colors of the different highlight regions that generate glow, or treat them all as grayscale brightness only (color controls later can change the effect). Grayscale is faster to process, but Color can result in some brilliant effects.
- **Brightness:** Sets the threshold at which highlights are isolated.
- **Gamma:** Lets you shape the isolated highlights.
- **Smooth:** Lets you blur details in the highlights that you don't want to be pronounced.
- **Color Filter:** Lets you choose a particular color of highlight to isolate (an eyedropper lets you select a value from the Viewer).
- **Operation:** Lets you adjust the resulting Isolation matte (options include Shrink, Grow, Opening, Closing) with a slider to define how much.

Aperture Controls

The Aperture controls let you define the shape and texture of the resulting glow this plugin creates.

- **Iris Shape:** Lets you choose a shape that determines how many arms the star pattern will have. Options are Triangle, Square, Pentagon, Hexagon, Heptagon, and Octagon.
- **Aperture Size:** Lets you alter the resulting diffraction pattern alternating between more of a star shape at higher values and a stippled wave pattern at lower values.
- **Blade Curvature and Rotation:** Lets you alter the softness and orientation of the arms of each star.
- **H/V Ratio:** Alters the horizontal/vertical ratio of the aperture, allowing you to replicate an anamorphic glow.
- **Angle:** Sets the angle of the aperture.
- **Chroma Shift:** Lets you introduce some RGB "bleed" into the glow.

Diffraction Controls

- **Result Gamma:** Lets you adjust how pronounced will be the glow that appears between the arms of the star patterns that appear.
- **Result Scale:** Lets you alternate between pronounced star patterns at high values and more diffuse glows at low values.

Compositing Controls

These controls let you adjust how to composite the glow effect against the original image.

- **Normalize Brightness:** This checkbox scales the brightness of the glow per frame. The Aperture Diffraction effect will keep to a consistent overall brightness as the scene changes.
- **Brightness:** Lets you adjust the intensity of the glow effect.
- **Colorize:** Lets you tint the glow effect using the Color control that appears below.

Glow

A sophisticated, soft glow effect that's highly customizable with only a few key parameters.

- **Select Output:** Lets you preview the image with different stages of the glow effect applied, viewing the Shiny Regions, the Glow Alone, or the Glowing Image.
- **Shine Threshold:** Defines the luminance level at which glow is triggered to appear on the image.
- **Alpha Masks Light Sources:** Check this box to use the input Alpha channel to exclude sources in those areas from casting light rays.
- **Alpha Limits Effect:** Check this box to use the input Alpha channel for compositing purposes. Unchecking means the input Alpha is ignored.

Shape and Spread

- **Spread:** Defines how far out shine extends from areas of the picture that trigger it.
- **H/V Ratio:** Lets you adjust the proportion of horizontal to vertical spread, allowing you to create "streaky" shine that extends farther in a particular dimension.
- **Relative Spread Red/Green/Blue:** Lets you adjust the spread within each color channel by a different amount, simulating a kind of chromatic aberration in the glow.

Color and Composite

- **Gain:** Adjusts the brightness of the glow effect.
- **Gamma:** Adjusts the spread of the glow effect and how it fades with distance.
- **Saturation:** Adjusts the intensity of the glow's color.
- **Color Filter:** A color picker and eyedropper let you choose a color with which to tint the glow.
- **Glow framing:** Lets you choose what happens when shine hits the edge of the frame, whether it's amplified by "Reflect in Camera" or whether it's moderated by a "Vignette" effect.
- **Composite Type:** Lets you choose a composite mode to use to blend the glow effect with the image. Defaults to Screen, which is good for gentle glows. Add lets you create hotter, more intense glows, while other composite modes let you create other varied effects.
- **Opacity:** Lets you adjust the transparency of the glow effect and is a fast way of "easing off" of a glow that you otherwise like, but that's too intense for the shot at hand.
- **Invert Effect:** Checking this box inverts the Glow parameters, so darker areas now affect brighter regions instead of the other way around.
- **Bright Region Recovery:** Adjust this slider to reclaim some image detail in areas that are blown out by the glow.

Lens Flare (Studio Version Only)

Simulates different kinds of lens flares resulting from the interplay of light through an aperture of selectable shape bouncing within layered optical elements in a lens. Four groups of controls give you a lot of ways to customize the presets to create your own effect:

Lens Flare Preset

You can choose a type of flare from the Lens Flare Preset drop-down. If you manipulate the controls to create your own effect, this drop-down switches to Custom.

Select Output

The Select Output drop-down lets you switch among the following viewing options:

- **Final Image:** (Default) Shows the lens flare composited against the current clip.
- **Flare Elements Alone:** Shows the isolated flare, making it easier to adjust.
- **Source Mask and Magnified Source Mask:** Let you see the mask used to control the lens flare brightness.

Light Source Masking

Three additional controls at the top let you create a quick and dirty luma key to create a mask that you can use for occluding the lens flare effect behind foreground elements in the scene. For example, if you're using lens flare to simulate the sun in the sky moving behind trees, these controls let you use those tree silhouettes to shift and modify the flare source accordingly.

- **Enable Light Source Masking:** This checkbox enables the Mask Threshold and Virtual Light Source Size sliders. You can then choose either Source Mask or Magnified Source Mask to see the mask that's created by raising the Mask Threshold slider.
- **Mask Threshold:** Raising this slider pulls a fast Luma Key that masks off darker foreground elements (such as trees against the horizon) and limits the flare to areas of the picture where the light source of the flaring can "shine through" (In this example, shining between the trees on the horizon).
- **Virtual Light Source Size:** This slider determines how quickly the center of a flare will disappear behind the luma-keyed mask you've created; higher values (simulating bigger light sources) cause a flare to disappear more slowly when passing "behind" a feature of the image that's being keyed via the Mask Threshold slider.

Position

Position parameters let you adjust the X and Y Position of the simulated light source that's causing the flare. There are three ways you can adjust the flare position.

- You can Adjust the X and Y Position sliders.
- You can turn on the OpenFX Overlay in the Viewer and drag the on-screen control.
- You can motion track elements within the scene using the FX Tracker.

Checking the Move With Sizing checkbox lets the lens flare retain its relative position in the frame if the Input and Editing sizing are changed.

Global Corrections

The Global Corrections group have parameters that let you quickly adjust the overall quality of the flare effect.

- **Global Scaling:** Lets you make every element of the flare effect larger or smaller at once.
- **Anamorphism:** Lets you stretch all flare elements horizontally to simulate an anamorphic lens' stretching effect.
- **Lens Center X and Y position:** Lets you offset the center of the simulated lens that's causing the flaring, about which the various elements of the flare pivot.
- **Global Defocus:** Lets you blur the overall flaring effect being created to soften the effect.
- **Global Brightness:** Lets you raise and lower the overall level of flaring being produced.
- **Global Saturation:** Lets you adjust the overall color intensity of the flaring.

- **Colorise Result:** Lets you choose how much to tint the flare, if at all. At a value of 0 (the default), no colorization is applied at all.
- **Colorization Color:** Lets you choose a color to use to colorize the flare via the Colorize Result slider above. You can use either a color control or eyedropper to sample color from the source RGB image of the current node.

Aperture

The Aperture parameters let you define the aperture of the simulated camera apparatus through which the flare is being generated. The shape defined by these parameters affects the look of the "starburst element" of each flare, as well as the look of any aperture-shaped "ghost elements" you're turning on.

- **Aperture Blades:** Defines how many blades make up the aperture. You can choose from 3 to 16 (defaults to 6). The diffraction of the lens flares is symmetric, so an odd number of blades will give you twice as many rays as the number of blades, while an even number of blades will give you the same amount of rays.
- **Angle:** Sets the angle of the resulting Aperture shape.

Elements

The Elements drop-down is a deceptively simple set of controls that let you expose the customization controls of each of the layers and elements that combine to create the simulated lens flare. Up to ten levels of elements can contribute to a lens flare effect. Each element and ghost shape has a different set of parameters unique to that type of element. Available elements in this pop-up menu include:

- **Full-Screen Glare:** A simulated overall flaring that covers the entire frame at its most intense. This glare increases as the flare nears the center of the screen and decreases as the flare moves toward the edges of the frame. Recommended for extremely big flaring effects. Parameters include:

  Glare Brightness: A slider; set this to 0 to eliminate glare.

  Glare Color: A color picker and eyedropper combination that lets you tint the glare.

- **Flare Spot:** Simulates the central light source that's triggering the flare. Parameters include Flare Size (set this to 0 to eliminate the flare spot), Flare Irregularity (which lets you create a more organic-looking, off-balance flare), Flare Softness, and Flare Color.
- **Starburst:** Rays of light stretching out from the center of the flare. Parameters include Starburst Size (set this to 0 to eliminate the starburst), Starburst Softness, Starburst Split Angle (which splits each streak of the starburst into a wider feathered pattern), Starburst Split Balance (which lets you adjust the brightness between each half of split streaks), and Starburst Color.
- **Ghost elements:** Seven available layers of Ghost Elements can be enabled and set to different optional shapes for each lens element you want to simulate. Each of the Ghost element layers can use one of five types of shapes, including:

  None: Turns that particular ghost element off.

  Aperture Shape: A polygonal shape defined by the number of blades in the aperture you've selected.

  Anamorphic Streak: A wide horizontal artifact typical of anamorphic lenses.

  Disc Shape: A round ring artifact.

  Bubble Shape: An oval with haze within.

  Corona Rays: A ring of streaks stretching outward.

Ghost elements share many parameters in common, although specific elements have unique parameters. These parameters are as follows:

- **Color:** A color picker and eyedropper combination that lets you colorize that specific element.
- **Position:** A slider lets you set that element's position along the optical path that's defined by the angle from the (Flare) Position X and Y to the Lens Center X and Y parameters. A value of 0 centers that element on the Lens Position, while larger values push that element farther and farther away from the Lens Position.
- **Size:** Sets the size of that flaring element, or in the case of the Anamorphic Streak, the width.
- **Height:** (Anamorphic Streak only) Sets the vertical thickness of the streak.
- **Center Brightness:** (Aperture, Disk, and Anamorphic Streak only) Defines the brightness in the middle of that element, filling it to appear as a solid element. Set this closer to 0 if you want the element to appear hollow.
- **Edge Brightness:** (All but Anamorphic Streak) Defines the brightness of the edge of that element. Raising this value while lowering the Center Brightness lets you create outlined element effects.
- **Softness:** Lets you blur that element.
- **Bristle Density:** (Corona Only) Lets you alter the number and arrangement of the optical bristles that appear. At lower values, fewer bristles appear, at higher values, more bristles appear. As you change the value of this parameter, the placement of bristles shifts, allowing you to change distribution as well as density with a single control.
- **Bristle Scale:** (Corona only) Lets you alter the thickness of the bristles that appear. Smaller values result in thicker bristles, higher values result in smaller bristles more tightly packed together.
- **Ringing:** (All types but Bubble) Simulates a pattern of diffraction artifacts. Higher values increase the number of rings or streaks comprising the element.
- **Chromatic shift:** Simulates chromatic aberration effects.
- **Eclipse Position:** Simulates where the outer (away from the center) or inner (toward the center) side of a Ghost Element is missing because the light is off the edge of a lens element or blocked by some part of the tube housing. Practically, this defines which side of the Ghost Element is affected by the other Eclipse parameters of size, softness, and chromatic shift. Adjusting this results in semi-circular ghost shapes of different kinds. At 0, there is no eclipse. At positive values, the eclipse starts from within the frame and pushes out; at negative values, the eclipse starts from the outside of the frame and pushes in.
- **Eclipse Size:** Defines the size of the eclipse region for that flare element. At higher values, more and more of the flare element is eclipsed.
- **Eclipse Softness:** Defines the softness at the transition from the eclipsed and non-eclipsed regions.
- **Eclipse Chromatic shift:** Lets you create a chromatic aberration effect at the boundary of the eclipsed region. At 0, there is no chromatic shift. At increasingly positive values, there's a shift toward blue. Toward negative values, there's a shift toward red.
- **Repeat:** Lets you use this element to spawn many duplicates defined by the following two parameters.
- **Repeat Position Seed and Repeat Size Seed:** At different values, these parameters let you pseudo-randomly redistribute the placement of repeated elements.

Lens Reflections (Studio Version Only)

Found in the ResolveFX Light category, Lens Reflections simulates intense highlights reflecting off the various optical elements within a lens to create flaring and scattering effects based on the shape and motion of highlights you isolate in the scene. It's an effective simulation that works best when there are light sources or specular reflections in the scene such as the sun, car headlights, light fixtures, fire and flame, or other lighting elements that are plausibly bright enough to cause such flaring.

Also, this plugin really shines when these light sources move, as each layer of simulated reflections moves according to that element's position within the virtual lens being simulated, creating organic motion that you don't have to keyframe. Without intense highlights, the results of this filter are good for more abstract light-leak effects.

(Previous page) Original image, (Above) Applying Lens Reflections

Output

The Output controls let you preview the image with different stages of the Lens Reflections effect applied.

- **Select Output:** Lets you choose to view the Isolated Source (to help when adjusting the Isolation controls), Reflections Alone (showing you the flaring effect that will be applied to the image by itself), or the Final Composite (the complete effect).
- **Alpha Masks Light Sources:** Check this box to use the input Alpha channel to exclude sources in those areas from casting light rays.

- **Alpha Limits Effect:** Check this box to use the input Alpha channel for compositing purposes. Unchecking means the input Alpha is ignored.
- **Quality:** This pop-up lets you choose how to render the effect. Options are Full, Half (Faster), and Quarter (Fast). The tradeoff is between sharpness and speed. The actual reflection process is the same across all quality levels. Smoother and lower resolution content will not benefit from the Full Quality setting.

Isolation Controls

The Isolation controls let you choose which highlights in the scene will generate lens reflections. The effect of these controls can be directly monitored by setting Select Output to Isolated Source. It's highly recommended to customize the Isolation controls for the image at hand when using this plugin, as even more so than other plugins, the particular highlights used will have a huge impact on the resulting effect.

- **Color Mode:** A pop-up menu that lets you either choose to keep the colors of the different highlight regions that generate lens reflections, or treat them all as grayscale brightness only (color controls later can change the effect). Grayscale is faster to process, but Color can result in some brilliant effects.
- **Brightness:** Sets the threshold at which highlights are isolated.
- **Gamma:** Lets you shape the isolated highlights.
- **Smooth:** Lets you blur details in the highlights that you don't want to be pronounced.
- **Color Filter:** Lets you choose a particular color of highlight to isolate (an eyedropper lets you select a value from the Viewer).
- **Morph Operation:** A pop-up lets you adjust the resulting Isolation matte (options include Shrink, Grow, Opening, Closing), and a slider lets you define how much.

  Morph Amount: Adjusts the edges of the light source based on the Morph Operation chosen.

Global Controls

The Global controls let you quickly and easily adjust the overall quality of the Lens Reflections effect using a centralized group of parameters.

- **Global Brightness:** Lets you raise and lower the level of all reflections. Lowering brightness is a good way to make a large lens reflection effect more subtle, although images with small lens reflection effects may benefit from being a little brighter.
- **Global Blur:** Lets you defocus all reflections. This is another good way of making lens reflection effects of all kinds more subtle.
- **Anamorphism:** Lets you deform the reflection elements to simulate an anamorphic lens' stretching effect.
- **Global Colorize:** Lets you adjust the color intensity of the reflections, either intensifying the color of all reflections or desaturating it.

Presets

A Presets pop-up provides a number of different settings to get you started. Selecting a preset populates the Reflecting Elements parameters below, at which point you can customize the effect to work best with the image at hand. It's highly recommended to customize these effects to suit the type of highlights in your image, in order to get the best results.

Reflecting Elements

There are four groups of Reflecting elements, each with identical controls. This lets you create interactions combining up to four sets of reflections. The controls found within each group are as follows.

- **Brightness:** Lets you adjust the intensity of that reflection.
- **Position in Optical Path:** Lets you shift the reflection according to an element's position in the lens. Practically, this means that positive values will enlarge an inverted reflection based on the highlights, while reducing values toward 0 will shrink the reflection, and pushing this into negative values will invert the reflection and pull it into the opposite direction as it begins to enlarge again. A value of –1 positions the reflection right over the highlight that creates it.
- **Defocus type:** Lets you choose what kind of blur to use, choices include Box blur, Triangular blur, Lens blur (the most processor intensive), and Gaussian blur (the default).
- **Defocus:** Lets you choose how much to blur that element.
- **Stretch:** Lets you give the flare an anamorphic widescreen look.
- **Stretch Falloff:** Lets you taper the edges for a less uniform stretching effect.
- **Lens Coating:** A pop-up lets you choose common colors such as purple, green, and yellow that correspond to different anti-reflective lens coatings, as well as a selection of other vibrant colors. Defaults to none. When you choose any other option, a color control and eyedropper let you manually choose a color or pick one from the image. A Colorize slider lets you vary how much to tint the reflection by the selected color, although setting Colorize to 0 lets the flare take its color from the source highlights of the image, which can sometimes give you the most interesting look.

Light Rays

A "rays of light" effect that simulates volumetric lighting emerging from light sources defined by a threshold you define. The effect mimics what are sometimes called "god rays" in the sky, or other highly directional glow effects.

Main Controls

The Main controls include:

- **Select Output:** Lets you preview the image with different stages of the Lightray effect applied, viewing the Final Image, Lightrays Alone, and Source Regions.
- **Source of Rays:** Lets you choose the emitter of the rays, using Bright Regions or Edges.
- **Source Threshold:** A slider that lets you choose the limit at which bright areas of the image emit rays.
- **Alpha Masks Light Sources:** Check this box to use the input Alpha channel to exclude sources in those areas from casting light rays.
- **Alpha Limits Effect:** Check this box to use the input Alpha channel for compositing purposes. Unchecking means the input Alpha is ignored.

Position

Position parameters let you define the direction rays take.

- **Ray Directions:** A pop-up menu that lets you choose either "From A Location," which exposes controls to let you choose an X or Y position to define a point of origin that defines the angle of the light beams, or "At an Angle," which exposes controls to let you choose an overall orientation for the rays.

Appearance

Appearance parameters let you customize the ray effect.

- **Ray Dropoff:** A pop-up with four options.

  Default (soft): Produces soft, indistinct rays of light that appear to fade away as they stream out.

  Keep Shape of Source: The edge of the light rays are defined by the shape that emitted them.

  CCD Bloom Harsh: Severely raises the brightness of the part of the image that's emitting rays as Length is raised, resulting in harsh glow or bloom in the image.

  CCD Bloom Soft: Gently raises the brightness of the part of the image that's emitting rays as Length is raised, resulting in a very gentle lightning of the image.

- **Length:** Lets you make the rays longer or shorter.
- **Soften:** Lets you blur the rays being emitted.
- **Brightness:** Lets you adjust how bright the rays are.
- **Gamma:** Adjusts the brightness of the ray effect using a gamma curve.
- **Saturation:** Adjusts the intensity of the ray's color.
- **Color:** A color picker and eyedropper let you define a color with which to tint the rays.
- **Composite Type:** Lets you choose a composite mode to use to blend the glow effect with the image. Defaults to Add, which is good for hotter, more intense rays. Screen lets you create more gentle rays, while other composite modes let you create other varied effects.
- **Bright Region Recovery:** Adjust this slider to reclaim some image detail in areas that are blown out by the rays.

Beauty (Studio Version Only)

Beauty is a plugin that lets you control texture. In Ultra Beauty mode, you can selectively smooth image detail that falls above a particular threshold, while preserving detail falling below a particular threshold. In this way, you can smooth larger textures you don't want, while either preserving or exaggerating smaller textures that you do want.

In the case of faces and skin, this plugin provides another method of smoothing larger, unwanted blemishes, while preserving desirable edge detail and underlying structures such as pores, so you can improve the complexion of subjects on shoots where hair and makeup was not available, without over-softening realistic skin details and creating an overly fake plastic look.

(Left) The original image, (Right) A face with Beauty applied to soften the complexion while retaining fine facial detail

Please note that this plugin is not only for skin detail, and it's not only for softening. Once you isolate the fine detail you want to preserve in a subject, you also have the option of exaggerating it to create highly textured results. This plugin is effective for any subject with textures that need refinement.

TIP: This plugin is best used within a qualification that isolates the particular feature you're trying to smooth. The default settings apply a moderate amount of smoothing and fine detail recovery that's appropriate for faces in closeup but will not be universally appropriate for all situations, so some fine-tuning will always be necessary. For naturalistic results, this plugin produces the best results when used in moderation.

Operating Mode

The Beauty plugin has three operational modes, including an Automatic mode with simpler operation when your objective is to create a maximally smooth or textured result while still preserving important details, an Advanced mode if you want more nuanced control, and an Ultra Beauty mode that provides additional controls that let you preserve fine detail that you want, while smoothing coarse details that you don't want.

Automatic

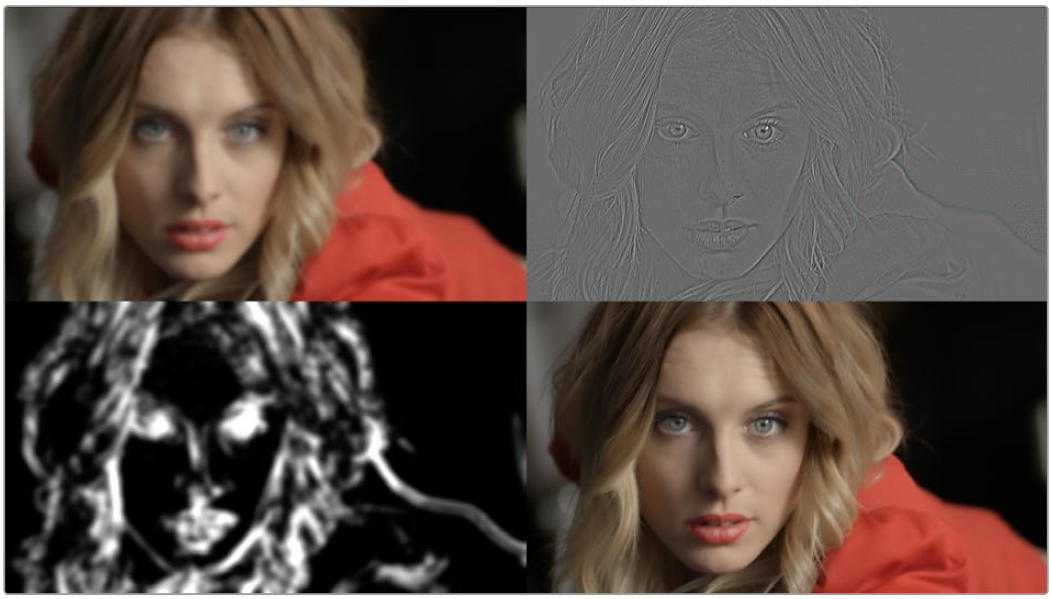
Automatic mode reveals easy-to-use controls for smoothing or coarsening detail.

- **Amount:** Lets you choose how much smoothing or coarsening to apply.
- **Scale:** Lets you reduce or increase the amount of smoothing or coarsening that's accomplished with the range of the Amount slider.

Advanced

Advanced mode reveals more manual controls for smoothing or coarsening detail, without the complexity of the Ultra Beauty mode.

- **Show Split View:** Checking this box puts a four up display in the Viewer showing the output of the Smoothing, Texture Recovery, Feature Recovery, and Final Output respectively. This is useful to have up when dialing in the advanced options below.



The Split View of the Advanced Beauty mode showing Smoothing (top left), Texture Recovery (top right), Feature Recovery (bottom left), and Final Output (bottom right) views.

Smoothing

These parameters let you remove imperfections. There are two smoothing controls to adjust. Apply these controls with enough strength to get rid of all the details to be smoothed away. The damage from over-smoothing will be reversed in Texture and Feature Recovery.

- **Smoothing Threshold:** Adjust this slider to set the amount of detail in the image to keep.
- **Diffuse Lighting:** Adjusts the amount of detail in the mid-tones.
- **Preview Smoothed:** Shows the result of just the smoothing operation in the Viewer.

Texture Recovery

These parameters let you restore areas of fine texture from the original video in flat areas away from the edges.

- **Texture Threshold:** Adjust this slider to set the amount of fine texture in the image to keep.
- **Add Texture:** Increases or decreases the scale of the texture in the Texture Threshold. Positive numbers add texture, while negative numbers remove it.
- **Preview Texture:** Shows the result of just the Texture Recovery operation in the Viewer.

Feature Recovery

These parameters let you determine how much of the recoverable Smoothing and Textures to bring back into the image.

- **Recovery Amount:** Adjust this slider to set the amount detail you've isolated (shown in white on the Feature Recovery view) to bring back into the image.
- **Preview Recovery Areas:** Shows the result of just the Feature Recovery operation in the Viewer.

Ultra Beauty

The Ultra Beauty controls reveal the full power of the Beauty plugin, with preview modes to examine different aspects of this plugin's behavior, while specifically adjusting the level of smoothing or coarsening you want, the amount of texture to preserve, and which additional features of the subject you want to recover from this operation to fine tune the result.

Smoothing

These parameters let you remove imperfections. There are two smoothing methods to chose from. Apply these controls with enough strength to get rid of all the details to be smoothed away. The damage from over-smoothing will be reversed in Detail Recovery. To see the effects of the smoothing alone, reduce the Detail Recovery strength, and texture to zero.

- **Flatten:** Reduces texture and filters out detail.

  Strength: How much smoothing effect is applied to the image.

  Levels: Controls how strongly abstracted the image is to smooth levels.

  Quality: Controls the sharpness of the resulting effect. Full being the sharpest and Fastest being the blurriest.

- **Filter:** Flattens smooth areas the image, leaving edges only where they divide flat regions from each other.

  Strength: How much smoothing effect is applied to the image.

  Filter Radius: Controls what scale of details are being filtered.

  Edge Threshold: Controls at what level an edge will be preserved or smoothed over. A low threshold will preserve even weak edges, while a high threshold will smooth over an increasing number of edges unless they are very high contrast.

Detail Recovery

These parameters let you restore the areas of the original video around the image edges, adding detail back into the image.

- **Strength:** Determines the amount of recovered detail.
- **Width:** Controls how far to either side of the edges image detail is recovered.

- **Gamma:** Controls whether to recover all edges, or only the stronger ones. A higher gamma reduces the amount of edges recovered.
- **Blur:** Softens the map of edges where detail is to be recovered.
- **Preview Edges/Details:** Enable this checkbox to show the areas where image detail is to be recovered; this allows you to see directly how the other controls in this section will affect the image.
- **Preview Recovery:** Enable this checkbox to show the actual detail being recovered alone over a neutral gray background.

Texture Recovery

These parameters let you restore areas of fine texture from the original video in flat areas away from the edges.

- **Texture:** Determines the amount of recovered texture to restore.
- **Scale:** Lets you set a threshold below which texture is extracted from the original image and applied to the result.
- **Detail/Edge Balance:** Lets you bias the recovery towards all textures (a negative value), or only to stronger details like edges (a positive value).
- **Preview Texture:** Enable this checkbox to show the actual texture being recovered alone over a neutral gray background.

Grain

These parameters let you add grain to the image to simulate detail in areas of the video with bad or no texture. Grain will only appear in smooth areas and will not cover the recovered edges.

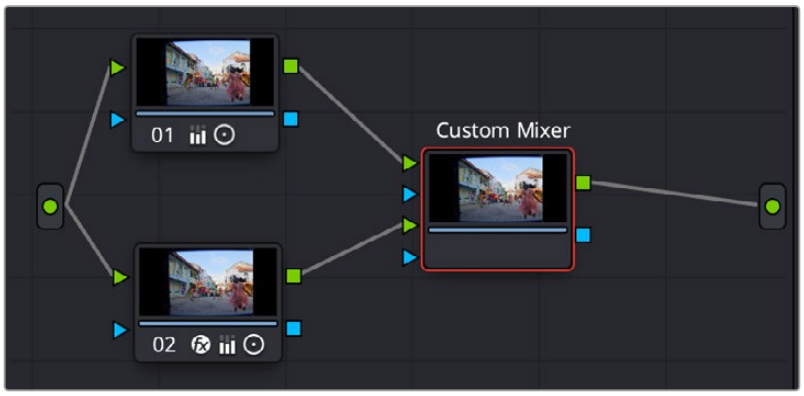
- **Strength:** Controls the amount of grain added to the image.
- **Size:** Controls the size of the individual grains.
- **Softness:** Softens the grain texture.
- **Saturation:** Applies saturation to the grain.

Custom Mixer

The Custom Mixer is an advanced version of the Layer node. It takes two inputs and combines them based on the Alpha channel of the second input. The Custom Mixer has controls to mix sources, blend effects, and interpolate between grades with per-channel control and mixing options. You can use this tool in a variety of ways to control the relative intensity between the sources, or simply as an alternative to the Layer Node but with slider controls.

The Custom Mixer should be added directly to the node graph and not dragged on top of a Corrector node. To add the Custom Mixer to your Node Graph, drag the Custom Mixer icon from the Resolve FX Refine section of the Effects library, directly into the Node Graph. You can also drag it on top of an existing link in the Node Graph to place it inline.

The Custom Mixer node is connected in the following way. The first and second RGB (Green) inputs are input 1 and input 2 respectively. The alpha of the second input controls the blend of input 2 onto input 1. The Alpha of the 1st input does not affect the result; it is passed through the node to the output key.



The Custom Mixer Node connections: Input 1 (Green triangle above), and Input 2 (Green triangle below). The alpha from Input 2 controls the blend of Input 2 onto Input 1 and is what you modify in the Custom Mixer controls.

The Custom Mixer has two main modes chosen by the Mix mode; both have the same behavior, just different controls to change how the input affects the output.

Blend

Blends the second input onto the first input. The normal range is from 0 (fully input 1) to 1 (fully input 2), however you can set the blend factor up to 10 times more or less by typing the numbers directly into the fields. This allows you to enhance the difference between inputs beyond the appearance of either one alone. All the sliders can be keyframed independently.

- **Blend Input 2 onto 1:** Controls the strength of each source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.
- **Gang:** Check this box to gang the channels of the custom mixer together, or uncheck to adjust separately.

Combine

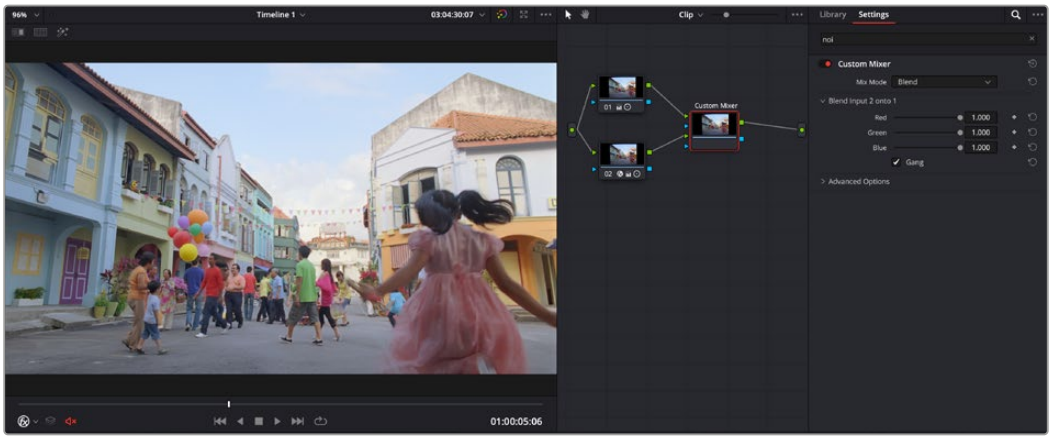
Combines the inputs together, allowing you to change the relative strength of each input's contribution to the mix. The normal range is from 0 (fully input 1) to 1 (fully input 2), however you can set the blend factor up to 10 times more or less by typing the numbers directly into the fields. This allows you to enhance the difference between inputs beyond the appearance of either one alone. All the sliders can be keyframed independently.

- **Input 1 Contribution:** Controls the strength of input 1's source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.
- **Input 2 Contribution:** Controls the strength of input 2's source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.
- **Offset:** Controls the offset of the combination, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.
- **Gang:** Check this box to gang the channels of the custom mixer together, or uncheck to adjust separately.

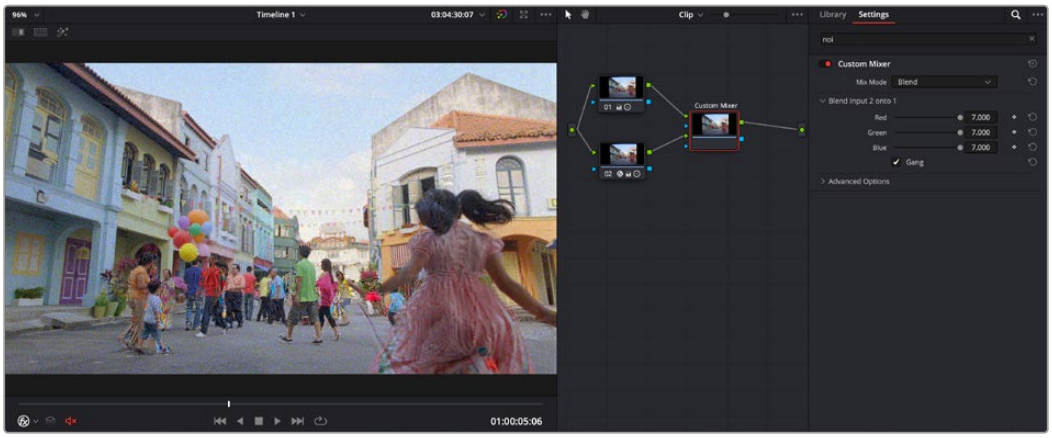
Advanced Options

Sets the composite type, as well as the color space and gamma of the resulting mix.

- **Composite Type:** Sets the composite type used for the mixer from the drop-down menu.
- **Color Space:** Sets the Color Space used for the blend. The default is the current Timeline color space.
- **Gamma:** Sets the Gamma used for the blend. The default is the current Timeline color space.



The initial setup of the Custom Mixer, Node 1 is the original image, Node 2 is identical but with a Noise Reduction effect applied to it.



The final setup of the Custom Mixer, by extending the blend factor by 7, the mixer actually adds noise to the image instead.

For the example above, by applying the Noise Reduction FX to Node 2, and directly connecting the same image from Node 1 to the Custom Mixer, the only difference between the inputs is the noise pattern from the effect itself. By manually turning the blend up past 1, you are blending in more of the noise than you started with. So by using Noise Reduction in conjunction with the Custom Mixer, you can actually add additional noise to an image that perfectly matches the original grain pattern without having to find a similar external grain or noise source.

Depth Map (Studio Version Only)

Depth Map creates an Alpha channel based on the perceived distance of objects in your clip. By being able to isolate a specific depth region, the opportunities to manipulate the resulting image are greatly expanded. For example, combined with a Fast-Noise plugin you could simulate a fog effect, but confined only to the distant background of your shot. You could enhance a foreground object like a person, increasing contrast, saturation, and sharpness, similar to using a qualifier. You can use a Depth Map to fix video issues, for example fixing a color temperature problem by isolating a far window that was shot in daylight causing background actors to be tinted blue, while leaving the foreground subject that was shot with studio lighting unaffected. Depth Map can also be combined with DaVinci Resolve's other windows and keying tools to form more complex rotoscoping and keys with less effort.

The resulting Depth Map Alpha channel is visualized as a black and white image, with white being the area that is affected by the resulting changes and black areas remaining unchanged.

The Depth Map creating an Alpha channel based on "distance"

Main Controls

These controls set the main parameters of the Depth Map.

- **Quality:** Depth Map is a very computationally intensive effect. The quality setting allows a Faster mode to speed up the responsiveness to adjustments, while the default Better mode gives the best results and should be turned on when the adjustments are finished.
- **Depth Map Preview:** By default this box is checked, and shows you the current Depth Map for making adjustments. When this check box is disabled, the resulting alpha can then be used for grading on other nodes. If you applied the effect to a corrector node, make sure to right click on the Depth Map's node and select "Use OFX Alpha" to have the node correctly pass the effect's Alpha channel.
- **Invert:** Checking this box reverses the Depth Map, switching its transparent and opaque regions.

Resulting Map Adjustment

These controls let you determine how the Depth Map's contrast is adjusted.

- **Adjust Map Levels:** When deselected (default), you can use DaVinci Resolve's grading tools (lift, gamma, gain, etc.) to adjust the full range of the Depth Map. When enabled, this option clips the Depth Map's levels to 0 and 1. This functions as a preview of what will happen to the Depth Map when used as an Alpha channel where the values are always clipped to 0 and 1 by DaVinci Resolve.

- **Far Limit:** This control adjusts the black levels of the Depth Map.
- **Near Limit:** This control adjusts the white levels of the Depth Map.
- **Gamma:** This control adjusts the intermediate depth values to be brighter or dimmer compared to the fixed black and white levels.

Isolate Specific Depth

These controls allow you to sweep backwards and forwards in the scene by depth, allowing you to isolate a specific depth range to adjust.

- **Isolation:** This checkbox turns the depth isolation tools on or off.
- **Target Depth:** This controls the specific depth you want to isolate. 1 is fully in the foreground, while 0 is fully in the background.
- **Tolerance:** Sets the range to either side of the Target Depth to include in the Depth Map.
- **Softness:** This sets a subtle ramp-in and ramp-out of the selected range, giving it a more organic selection.

Map Finesse

These controls modify the resulting Depth Map's Alpha channel for use in grading.

- **Post Processing:** This control turns the Map Finesse tools on or off.
- **Contract/Expand:** This control dilates or erodes the overall shape at the edges, useful for fine tuning the boundary between the affected and unaffected regions of the map.
- **Blur:** This control softens the boundary of the map, allowing it to blend more smoothly into the resulting image.

Advanced Options

These controls tell the Depth Map how to handle various blanking issues.

- **Blanking Regions:** These controls tell the Depth Map how to handle letter and pillar boxing regions in the effect.

  Process Entire Frame: Tells the AI to ignore any information about the timeline shape and just process all the visible pixels.

  Handle Automatically (default): The AI will process only the area that DaVinci Resolve knows your media is in.

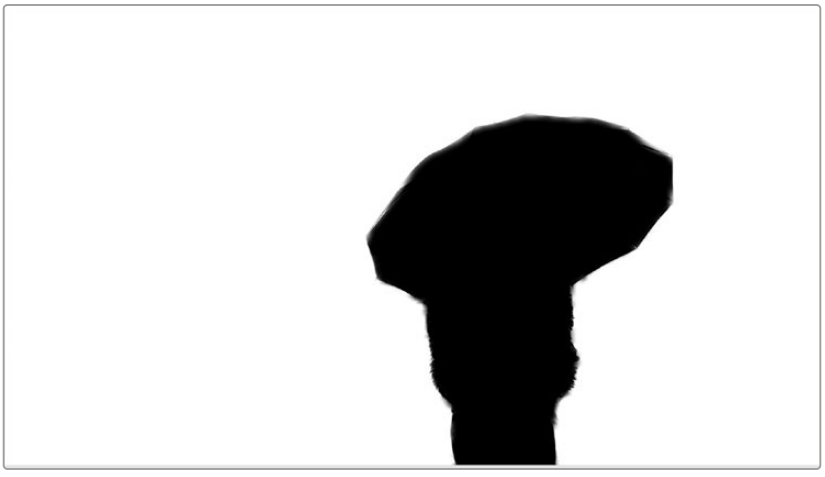
  Auto + Extra Crop: This is recommended for cropping away black bars; it uses DaVinci Resolve's knowledge of which pixels were occupied by your media but lets you crop out the framing or letterboxing relative to its shape. This is recommended because it will stay consistent as you adjust Timeline settings.

  Manual Cropping: Simply lets you override whatever the framing of the content is, ignoring any of DaVinci Resolve's knowledge of the shape of your media.

  For example, say you have footage shot of a person on a rainy day, but the background is too distracting and contrasty. By creating a depth map that isolates only the foreground person, we can then apply a Fast Noise smoke effect to only the background, making it look like a foggy mist, and less distracting.

The original footage with a distracting background

The same footage with a Fast Noise Smoke effect node to simulate a fine mist, however it covers the entire frame, including the main subject. The mist belongs in the background only to be more realistic.



By placing a node with Depth Map applied between the original nodes, you can use the effect to pull a key based solely on “distance” from the camera. In this case, we have selected the background (white) and excluded the woman with the umbrella (black). Note the fine detail in the furry coat, which would be difficult to get with an HSL or window qualifier.

The final result of the process shows the main subject in the foreground with the Fast Noise smoke effect limited only to the background.

TIP: To create more believable Depth of Field adjustments, use the Depth Map effect in conjunction with the Tilt-Shift Blur effect. You can feed the results of the Depth Map directly into the Tilt-Shift Blur effect as a blur map by connecting the key output of the Depth Map node to the key input of the Tilt-Shift Blur node and selecting “From Alpha In” in the Map Source drop-down in the Depth of Field section of the effect. From there adjust the Focus Sweep to dial in the area you want to isolate. If you’re not getting the expected results, try inverting the Depth Map.

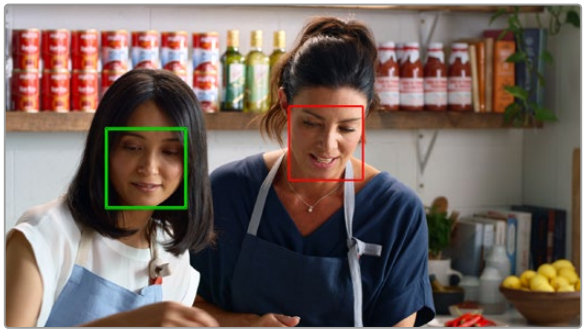
Face Refinement (Studio Version Only)

The Face Refinement effect has been improved with better tracking, profile handling, and smooth skin options. The newly revised effect is described below.

Face Refinement is an incredibly sophisticated, yet easy-to-use, filter that lets you quickly make very targeted adjustments to people’s complexions.

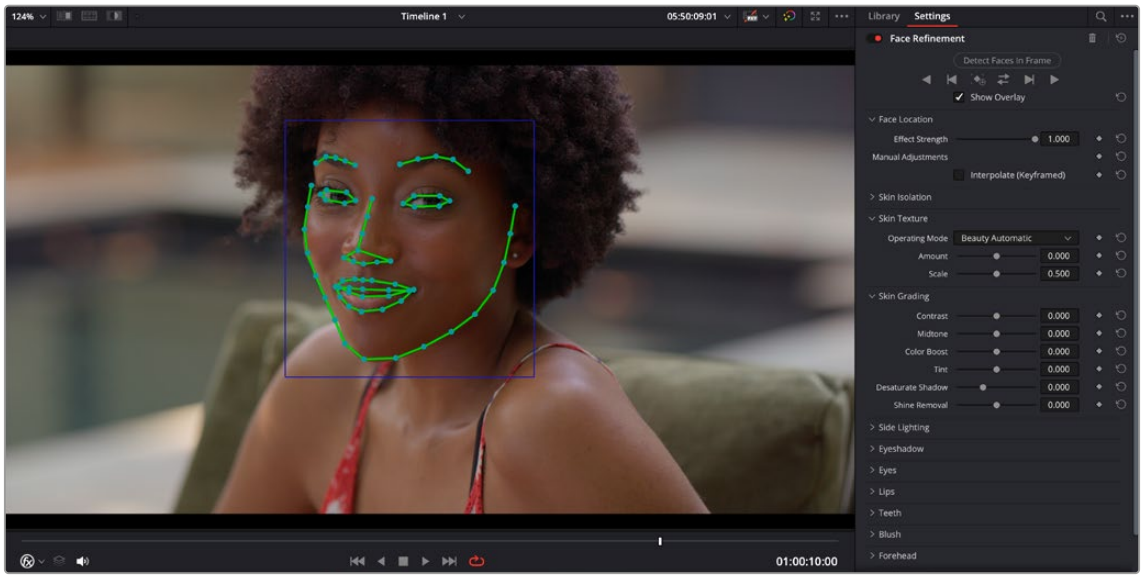
In order to use the face refinement toolset, the first thing you need to do is to identify the face (or faces) you wish to work on, and then analyze and track that face through the clip.

Identifying a face is done by clicking on the Detect Faces in Frame button. If faces are present in the frame at the position of the playhead, then this results in boxes being drawn over each detectable face. Click any of these boxes to choose which face you want to refine, and that box will be highlighted in green to indicate which face you’ll be refining.



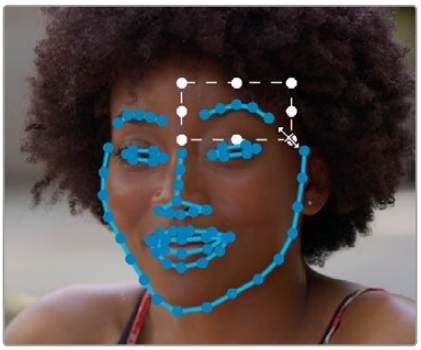
When multiple faces are detected, you can click a box to choose which one to work on.

After you've selected which face to work on, you need to use the tracking controls to track the face through the clip, and an outline of the face's major features appears to let you follow its progress.



The Face Refinement filter detecting a performer's face

The basic tracking controls usually work well enough to track faces in most instances. However, in some tricker cases if the subject's head tilts away, or if it's occluded by something else in the frame, you may have to manually adjust the track. You can do this by going to the last known good point of the track and then checking the Interpolate (Keyframed) box. This will add keyframes automatically for the frame and turn the outlines blue to let you know you are in manual mode. Then you can go to the problematic frames and click and drag to manually adjust the entire face or select and adjust each individual feature as needed. Once you get to a point where the automatic tracking works again, you simply uncheck the Interpolate box and let the automatic tracker take it from there.

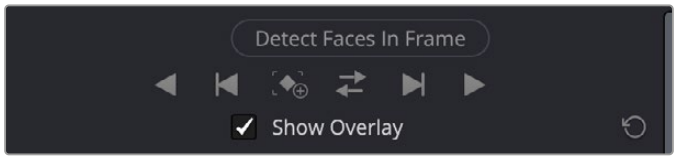


Manually adjusting an eyebrow in the Interpolate (Keyframed) mode

Once the face has been tracked, you're ready to work. This plugin divides the tracked face into different zones for common operations colorists often perform to quickly eliminate blemishes, adjust the hue and saturation of complexions in regionally appropriate ways, modify lighting, sharpen desirable detail, and refine makeup. Because all adjustments are fit to the proportions of the face that's been detected and tracked, all you need to do is make the adjustments you need and DaVinci Resolve takes care of the rest.

Main Controls

The top controls let you initiate the Face Refinement process.



The tracking controls for Face Refinement

- **Detect Faces in Frame:** This button initiates the process of using the facial detection of the Face Refinement plugin to detect the face you want to make adjustments for.

  Tracking Controls: Basic tracking controls to identify facial features motion through the clip

  Track Reverse: Identifies the face and tracks it backward through the clip.

  Track Reverse 1 Frame: Identifies the face and tracks it backward 1 frame.

  Find in Frame: Identifies the face in the current frame.

  Track Forward then Reverse: Identifies the face then tracks it forward from the current position and then reverse from that position.

  Track Forward 1 Frame: Identifies the face and tracks it forward 1 frame.

  Track Forward: Identifies the face and tracks it forward through the clip.

- **Show overlay:** To impress your clients and see how well Face Detection is tracking the face you're working on, you can turn on this checkbox, which turns on the wireframe tracking that shows you which facial details are being detected.

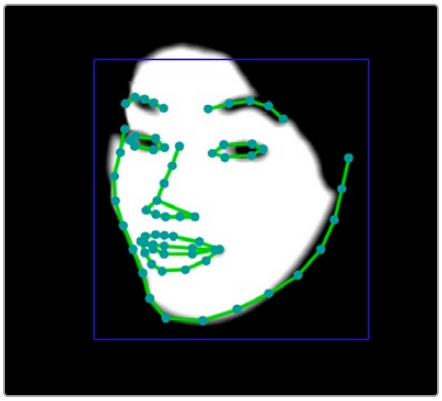
Face Location

These controls let you adjust the strength of the effect, as well as make manual adjustments to the face and its features position in the frame.

- **Effect Strength:** This slider determines the relative strength of the adjustments made with the original image. 1.000 is full strength, while 0 turns the effect completely off.
- **Interpolate (Keyframed):** Checking this box lets you make manual adjustments to the face and feature tracking in the Viewer, and automatically keyframes any changes. Click and drag in the Viewer to move the entire face. Shift-click and drag to reframe the face. Click on any individual feature to adjust, or any dot to move its position.

Skin Isolation

These controls let you adjust the skin mask this plugin automatically generates in order to limit the effect to only the face of the person you're targeting.



Adjusting the key with the face mask active

- **Show mask:** This checkbox makes the face mask being generated visible, which can be helpful to see while you're tuning it.
- **Skin Mask Source:** Lets you select the source for the skin mask. DaVinci Resolve's Internal Skin Model is the default, but there is the ability to use the Input Alpha if you've qualified the skin tones in another node. None disables the mask.
- **Shadow Range:** This control lets you extend or erode the shadows of the face detected by the skin model.
- **Tint Range:** This control lets you extend or erode the tint range detected by the skin model.
- **Temp Range:** This control lets you extend or erode the color temperature of the face detected by the skin model.
- **Limit to Face Region:** Turning on this checkbox places a circular garbage mask that follows the face to eliminate any accidental qualification of areas outside the face.
- **Region Size:** Lets you adjust the size of the face mask.
- **Region Softness:** Lets you adjust the edge softness of the face mask.
- **Flat Skin Areas Only:** Checking this box will exclude the nose and eye socket regions from the mask, allowing you to work only on the facial skin itself.
- **Exclude Mouth:** Checking this box will exclude the mouth region from the mask, allowing you to work only on the facial skin itself and not the lips.
- **Denoise mask:** This slider lets you fill in areas of small detail in the mask.
- **Refine mask:** This slider lets you adjust the face mask to smooth or eliminate gaps in the key.

Skin Texture

The Skin Texture controls have three operating modes that let you choose the method you want to use to control skin texture. Beauty Automatic and Beauty Advanced provide the texture controls available in the Beauty plugin, while Smoothing provides the previously available texture adjustment controls.

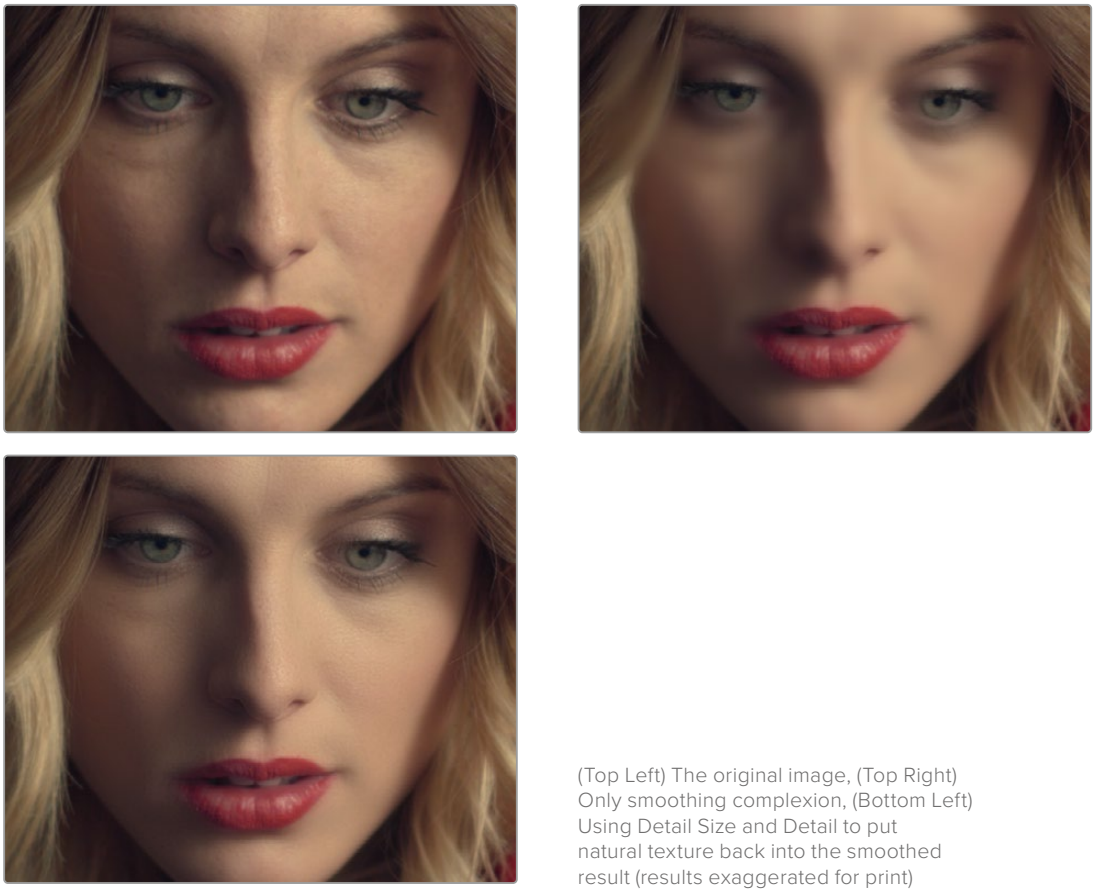
Beauty Automatic Controls

Automatic mode reveals easy-to-use controls for smoothing or coarsening detail.

- **Amount:** Lets you choose how much smoothing or coarsening to apply.
- **Scale:** Lets you reduce or increase the amount of smoothing or coarsening that's accomplished with the range of the Amount slider.

Smoothing Controls

- **Smoothing:** This slider removes detail from the areas isolated by the Skin Mask controls, smoothing the complexion. Its operation depends on the settings of the Detail Size and Detail sliders below. You may find you can increase Smoothing more dramatically as you increase Detail using the Detail Size and Detail sliders described below.
- **Detail Size and Detail:** Once you've used the Smoothing slider, you can then use these sliders to selectively put subtle skin details back into the image; Detail Size determines the maximum size of details you want to put back into the face, and Detail is a sharpening operation that lets you adjust how visible these small details are. By combining smoothing and subtle preservation of small details, you can get a much more naturalistic result than were you to simply leave the entire face unnaturally smooth.



(Top Left) The original image, (Top Right) Only smoothing complexion, (Bottom Left) Using Detail Size and Detail to put natural texture back into the smoothed result (results exaggerated for print)

Beauty Advanced

These controls are identical to the Advanced controls of the Beauty plugin, covered previously in this chapter.

Color Grading

These controls let you make color adjustments to the overall face.

- **Contrast:** This slider lets you lighten the face in a natural way by keeping the shadows dark, even while you brighten the face, making it easy to bring actors out of the background.
- **Midtone:** Lets you add a more luminous quality to the skin tone.
- **Color boost:** Specifically boosts saturation in the lowest saturated parts of the face.
- **Tint:** Provides a limited range of naturalistic hues emphasizing orange through red (but extending to green and magenta) with which to tweak complexion.
- **Desaturate shadow:** This slider lets you selectively desaturate the darkest shadows on the face to keep things looking natural, or to desaturate more aggressively in order to stylize the face in a different way. Also useful when using the other adjustments of this plugin makes the shadows too colorful. Moving this slider into negative values will add saturation.
- **Shine Removal:** This slider is an inverse contrast adjustment designed to ameliorate sweat and shine on a person's face, although moving this slider into negative values will also accentuate shine.

Side Lighting

These controls allow you to fill in or accentuate shadows and balance the light between the sides of the face.

- **Lift Left/Right:** Adjusts the dark parts of the image for a side of the face.
- **Gamma Left/Right:** Adjusts the midtone parts of the image for a side of the face.
- **Gain Left/Right:** Adjusts the bright parts of the image for a side of the face.
- **Area Size:** This control lets you adjust the size of the area of influence of the side lighting.
- **Bias Left/Right:** Normally the left and right sides of the face are split right down the nose. You can use this control to manually adjust the center of the effect, if necessary.
- **Area Softness:** This control adjusts the softness of the effect around the side of the face.

Eye Shadow

These controls give extensive control of the eyelids and sockets, without manipulating the eyes themselves. Used subtly, it can easily remove bags under the eyes, or accentuate makeup details. Used aggressively, you can create realistic eye makeup effects from nothing. There are separate controls for the upper and lower eyelid areas.

- **Temp Upper/Lower:** Adjusts the color temperature of the eyelid.
- **Tint Upper/Lower:** Adjusts the tint of the eyelid.
- **Hue Upper/Lower:** Adjusts the color of the eyelid.
- **Saturation Upper/Lower:** Adjusts the saturation of the eyelid.
- **Gamma Upper/Lower:** Adjusts the gamma of the eyelid.
- **Size Upper/Lower:** Adjusts the size of the area of the eyelid modifications.
- **Softness Upper/Lower:** Adjusts how soft the blending is between the eyelids and the face.
- **Strength Left/Right:** Lets you set different strengths for the left or right eye to compensate for lighting differences between the sides of the face.

(Left) The original image, (Right) using the Eyeshadow tools to change the model's upper eyeshadow color to purple and increase the intensity

Eye

These controls target just the eyes and surrounding area of the face.

- **Sharpening:** This slider lets you selectively add sharpening just to the eyes and eyelashes, which lets you instantly add focus to any performer.
- **Brightening:** This slider lets you whiten the eyeballs.
- **Eye Light:** This slider lets you brighten the region of the face around the eyes that's often thrown into shadow by the subject's forehead in situations with imprudent lighting.
- **Eyebag Removal:** This slider uses a variety of techniques to smooth, color-adjust, and brighten the area under the eyes most susceptible to eye bags with tired talent.

(Left) Eyes with no special adjustment, (Right) eyes with adjustment

Lips

These controls target just the lips and surrounding area of the mouth.

- **Hue Shift:** This slider lets you adjust the color of a subject's lips or lipstick.
- **Saturation:** This slider lets you adjust the intensity of lip color.
- **Gamma:** This slider lets you adjust the lip brightness using a gamma curve.
- **Upper Lip Smooth:** Lets you smooth out fine age lines that can appear above lips.
- **Mouth Corners Inner/Outer:** Adjusts the side corners of the mouth.
- **Top Inner/Outer:** Adjusts the top boundary of the lips.
- **Bottom Inner/Outer:** Adjusts the bottom boundary of the lips.
- **Softness:** The softness of the blend between the mouth area and the rest of the face.

Teeth

A smile can hide a thousand lies, but just these three controls can accentuate the teeth.

- **Blue Gain:** This control is used to color balance the teeth, making them whiter or yellower as desired.
- **Gamma:** This manipulates a gamma curve allowing you to set how bright a smile the subject has.
- **Mask Softness:** The softness of the blend between the teeth and the rest of the face.

Blush

The parameters in this group let you modify the hue of the blush region of a subject's cheek, letting you correct an unwise makeup choice, or push a subject's blush color around to add makeup that wasn't there.

- **Hue:** This slider lets you adjust the hue of the cheeks.
- **Saturation:** This slider then lets you intensify or remove blush color.
- **Size:** This slider lets you adjust the size of the blush area of the cheeks.

About Forehead, Cheeks, and Chin Retouching

The next three groups of controls borrow a technique from portrait painters, who've long taken advantage of the "traffic light" approach to rendering skin hues that observes that foreheads are often a bit yellow, the middle of the face is usually a bit red, and chins can be a bit green. A combination of unequal sun exposure, capillary distribution, and follicle growth account for this, but the bottom line is that faces are seldom a single unified hue. This means that there may be a region of the face that would benefit from individual adjustment (cheeks that have gotten too much sun, for example). But it also means that when you allow a bit of hue variation into your face grade, you can achieve a more naturalistic result.

(Left) A face graded with a single hue, (Right) a face graded with slight variation in the forehead, blush area, and chin

TIP: For a variety of reasons, people are extremely sensitive to the hues of skin tone, so tiny variations that can be difficult to identify nevertheless have a significant impact on the resulting visuals. Unless you're aiming to create a special effect, these controls are meant to be used sparingly.

Forehead

As the name implies, adjusts color and texture on the forehead.

- **Hue and Saturation:** These sliders let you adjust forehead color.
- **Gamma:** This manipulates a gamma curve allowing you to set how bright the forehead is.
- **Smooth:** This slider lets you apply a specific smoothing operation to the forehead to ameliorate wrinkles and worry-lines.

Cheeks

Simple color adjustment controls affecting the entire cheek area, and not just the blush area.

- **Hue and Saturation:** These sliders let you adjust the color of the cheek, eye, and nose area.

Chin

Simple color adjustment controls over the chin of the face.

- **Hue and Saturation:** These sliders let you adjust the color of the chin, running up alongside the sides of the face (the beard area).

Relight (Studio Version Only)

Relight allows you to add light sources to your scene, realistically illuminating the objects within it. Unlike a Power Window whose shape is fixed on screen, Relight analyzes the shapes of people and objects to create a Surface Map and uses that map to reflect light appropriately. When dialed-in properly, this effect can provide the illusion of light following the curves of an object, reflecting off highlights, and disappearing into shadows.

Relight is useful in situations when you wished you had another light in the scene, want to accentuate an existing light to match another shot, or increase the realism of day-for-night grading.

NOTE: The Relight effect creates the illusion of depth with its analysis of the surfaces in a scene, but it does not calculate 3D relationships between objects in the scene. Shapes cannot be made to cast shadows, and depth information cannot be produced.

Setting up Relight

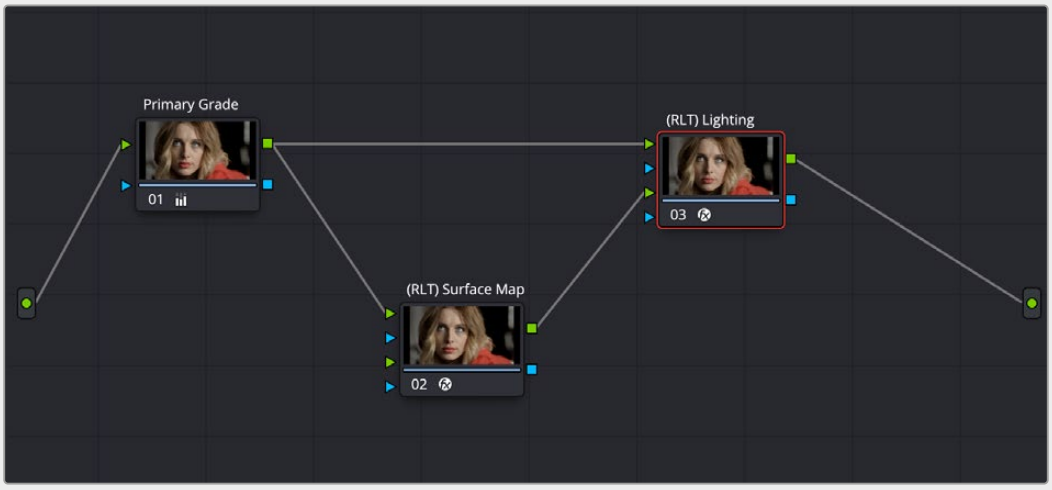
Analyzing the image to create a Surface Map is very computationally intensive. Calculating the effects of light sources to an existing analysis is comparatively very fast. By default, adding Relight to a node will create the map and add a light in one step. This is convenient, but adjusting the light position re-runs the effect, and hence re-runs the analysis. So it can be slow to work with unless you have an extremely powerful computer. Fortunately it is possible to split the work across two nodes, caching

the analysis in the first node and adjusting the light positions in the second node. This is described in detail below.

Note that you can add multiple light sources reusing the same analysis. If you have, say, three separate lights in the same scene, reusing one analysis, then this will run three times faster than repeating the analysis for each light.

And as an advanced option, the split approach allows you to use a Surface Map which has been saved out to file, or a Surface Map from other software. Computer graphics software can often render “surface normals” of 3D models along with the images they create and these can be made compatible with Relight. In this context a “normal” is a geometric term describing which way a surface is oriented. There is no universal format for surface normals; see the External Map settings for some options which can help with using these as Surface Maps in the plugin.

Here is a sample node graph splitting the Relight in two:



How to set up a dual Relight Node Tree with two separate Relight nodes, configured as above. These have been labeled Surface Map and Lighting for clarity.

In the above example, you have the source video and two Relight nodes. This is how they’re set up:

- The source video is connected to the first RGB input (top green triangle) of both nodes.
- The first Relight Node ((RLT) Surface Map) creates the Surface Map for the image by selecting “Output Surface Map” checkbox in the Relight effect’s settings. When checked, the plugin goes into analysis-only mode and other options disappear. You can enable Node Caching to automatically generate the Surface Map in the background when you aren’t using DaVinci Resolve. The RGB output of this node is connected to the second RGB input (bottom green triangle) of the second Relight Node.
- In the second Relight Node ((RLT) Lighting), set the first option “Surface Map” from its default (“Use Internal”) to “Use Input 2.” The other settings all remain visible; this node is where you will adjust the light properties.

You can add Power Windows, Qualifiers, or masks to either node, or to separate nodes and connect them via the first Alpha channel (top blue triangle) of either node. For example, you could select a person using the magic mask and use it to limit the lighting to just that person and not the background.

The output of the Relight Surface Map.
This goes into the input of the Relight Lighting node.

Using Relight

When first placing Relight on a node and turning off the lighting preview, there is no visible change to the image. This is because the map of what the light is illuminating is in the Alpha channel, ready for all of DaVinci Resolve's color grading tools to go to work. The simplest place to start is to increase Gain (dial it up directly or add color); often changes to gamma and saturation may be appropriate.

For a day-for-night effect you can invert the Alpha to darken all of a scene except the light areas, to achieve a day-for-night effect but with a "light source" that is the original scene lighting.

The Relight Settings

These controls allow you to adjust the intensity, type, and direction of the light that reflects off the surface map. Most are keyframable, and positions can be attached to the FX Tracker, allowing things like moving a light source as if it were attached to an object, or moving a spotlight to follow a person as they move through the scene. Controls and their groups are:

- **Surface Map:** This chooses which mode you will use to create the Surface Map.

  Use Internal: Generates the Surface Map and immediately uses it in this node.

  Use Input 2: Receives the Surface Map from another Relight Node. Use this on the second node of a dual Relight Node setup.

- **Output Surface Map:** Checking this box causes this copy of the effect to output a multi-colored map of the input frame. This Surface Map can then be fed into a second Relight effect (set to "Use Input 2" as above) where the light sources are placed and adjusted.
- **Directional/Point Source/Spotlight:**

  Directional: Creates a light source that emits from a specific direction at an infinite distance.

  Point Source: Creates a light source that emits from a central point.

  Spotlight: Is also a point source but it is directed into a cone shape.

- **Relighting Map Preview:** Checking this box reveals the Alpha channel of the effect of this light. Unchecking this box shows the current image but with the light mask in the Alpha channel.
- **Diffuse Reflection Properties:** These controls determine the quality of the emitted light.

  Brightness: This controls the strength of any grading that is applied to the scene. It does not add brightness changes on its own but amplifies the changes you make in the grading tools.

  Softness: This controls the size of the light emitter, effectively determining how harsh or gentle the gradient is between light and dark.

  Distance Falloff: This controls how much reflections will dim with distance to the light source.
- **Light Properties:**

  Brightness: This controls the strength of any grading that is applied to the scene. It does not add brightness changes on its own but amplifies the changes you make in the grading tools.

  Reach: This controls how much reflections will dim with distance from the light source.

  Contrast: This determines how harsh or gentle the gradient is between light and dark.
- **Surface Properties:**

  Glossiness: Gives the illusion of a metallic sheen to reflective surfaces.

  Specularity: When there is any glossiness added, this controls how metallic/shiny that glossiness is.

  Shadow Softness: Controls how much the light penetrates into shadows due to ambient reflections, beyond where it would reach otherwise.
- **Spotlight :**(shown only with Spotlight option enabled)

  Beam Angle: Sets how broad the cone of light is. This control is also available graphically in the Viewer.

  Edge Softness: Controls the softness of the edges of the light cone/beam.
- **Light Position:** These controls are for the the position of the light emitter for all light types. They can be adjusted directly, but more easily, they can be adjusted graphically in the Main Viewer. Ensure that the Main Viewer's mode is set to Open FX Overlay with the icon at the bottom left.

  In Directional mode:

  Azimuth/Elevation XY : Controls the direction the light is coming from.

  In Point and Spotlight modes:

  Source Follows FX Tracker: Check this box to have the light source follow the FX tracker.

  Light Source XYZ: These controls determine the light emitter's position in 3D space.

  In Spotlight mode:

  Spot Follows FX Tracker: Check this box to have the light source follow the FX tracker.

  Spot Target XY: These controls determine the position of the base of the spotlight cone.

When you are in Use Input 2 mode, there are options for using an externally-generated Surface Map.

- **Rescale Oversaturated:** Different applications use different scalings of the Surface Map. A common format looks like the Relight plugin's internal ones but with the colors intensely saturated and can be dark or black in some areas. If your imported surface map has this appearance, check this box to re-interpret it.
- **Reinterpret Left/Right:** Check this box to swap the direction of your external surface map if your map surfaces are appearing concave instead of convex.
- **Reinterpret Up/Down:** Check this box to swap the direction of your external surface map if your map surfaces are appearing lit from below when the light is above them.

When you are generating an analysis internally with Use Internal, or you are using Output Surface Map, you will also see an Advanced Options group with an option related to Blanking Regions. These will not apply in the majority of cases; they are only for fixing some specific situations. They are for forcing different behavior at the edges of the frame in these special cases:

- The source video has letterboxing or some framing border “baked in,” meaning that the incoming frames have black pixels at the edges that were not added by DaVinci Resolve. Letterboxing added by DaVinci Resolve (e.g., a 21:9 frame fit to a 16:9 timeline) does not need any special treatment. You will recognize that there is a problem because the Surface Map AI will treat the scene as if the black areas are actually objects or attached to objects in frame. Objects in contact with the black bars may appear to blend into those areas.
- The source video has pillarboxing, same as with letterboxing above. For example, if a 4:3 source video was captured to a 16:9 clip with black borders before it was used in DaVinci Resolve.
- A case where a wide clip was inserted into a narrower timeline correctly, but after resizing or effects were applied you wish for the plugin to process the original blanking areas because there is now content there. This case will appear obvious, in that the analysis will stop at the original blanking boundary, cropping-away areas you want to analyze.

If you encounter any of these special cases your options are:

- **Blanking Regions:**

  Process Entire Frame: Tell the AI to ignore any information about the timeline shape and just process all the visible pixels.

  Handle Automatically (default): The AI will process only the area that DaVinci Resolve knows your media is in

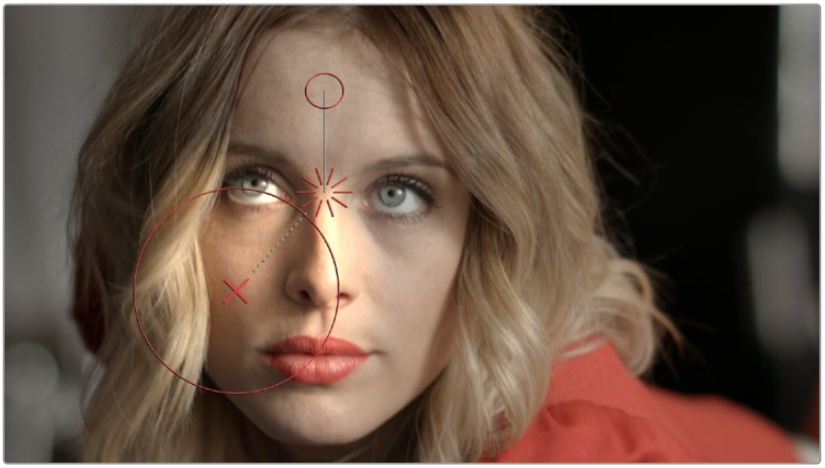
  Auto + Extra Crop: This is recommended for cropping away black bars, it uses DaVinci Resolve’s knowledge of which pixels were occupied by your media but lets you crop out the framing or letterboxing relative to its shape. This is recommended because it will stay consistent as you adjust timeline settings.

  Manual Cropping: Simply lets you override whatever the framing of the content is, ignoring any of DaVinci Resolve’s knowledge of the shape of your media.

The Relight On-Screen Controls

Several of the controls for positioning the light source are available graphically in the Viewer; make sure that Open FX Overlay is selected in the lower left of the Viewer to see them.

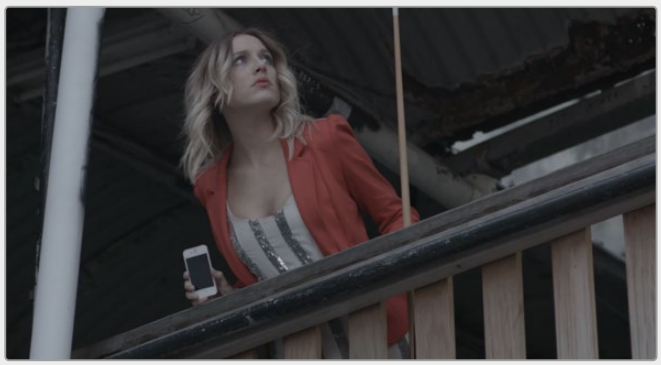
In the Directional mode, you can drag the emitter (red rays) around the frame to set the Azimuth/Elevation controls.



In the Point Source and Spotlight modes, you can move the emitter (red rays) to change XY coordinates, and the circle to adjust the emitter's Z coordinates. If in Spotlight mode you can drag the X to change the XY coordinates of the Spot Target, and scale the large circle to adjust the Cone Angle.

Example

In this example, we will be relighting the scene below. Shot during a cloudy overcast day, the director likes the flat look on the building. Unfortunately, the muted drab lighting also affected the model, which he wants to pop more out of the scene. We are going to use the Relight tool to add a phantom sunbeam directly to the model and not to any of the surrounding fence or walls.

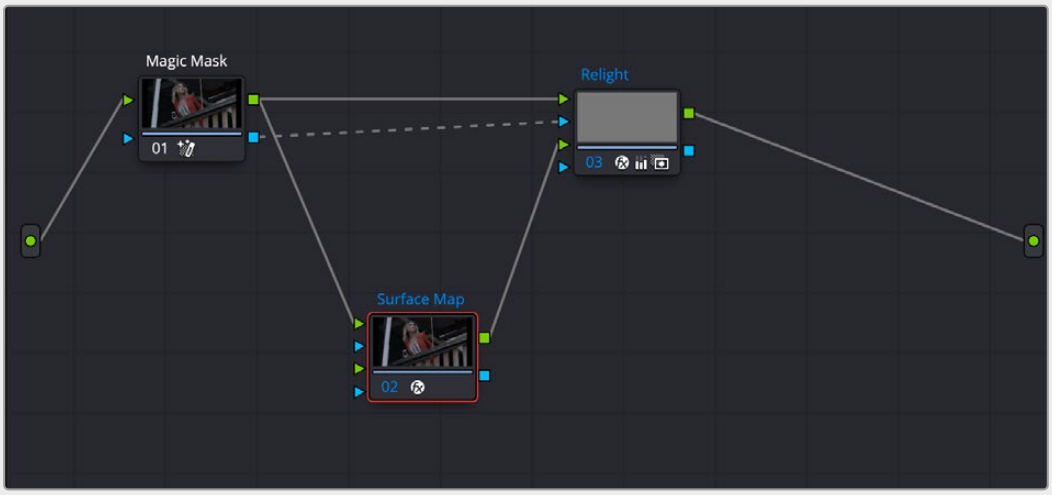


The model's lighting is flat and drab. We want to change it by adding an artificial sunbeam falling on her that wasn't there in the shot. We also want to keep the fence and background as they are.

The first tool we will use is the Magic Mask to isolate the model from her environment.

Isolating the model with a Magic Mask to isolate the effect

Next we will add two different relight nodes, one to create the surface map, the other to receive it and actually relight the shot. The node tree is explained below.



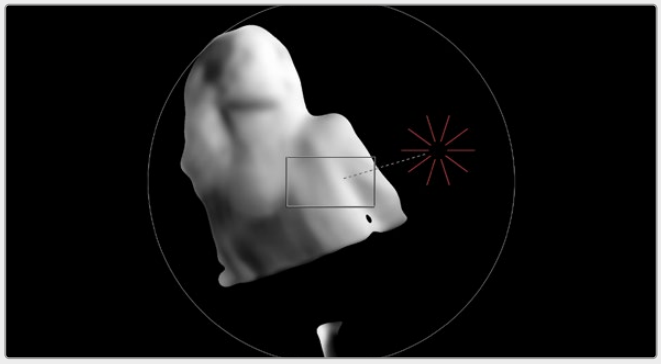
The Relight node tree; there are two Relight nodes, one called Surface Map and one called Relight.

We feed the RGB output of the Magic Mask to the top RGB inputs of both nodes. We also feed the Alpha output of the Magic Mask into the Relight node. This way the Relight effect will only apply to the model we selected using the Magic Mask and leave the background alone.

In the first node (Surface Map), we select Use Internal from the Surface Map option. We also check the Output Surface Map checkbox to pass that generated map to the second (Relight) node. We then complete the connection by dragging the RGB output of the Surface node to the bottom RGB input of the Relight node. In the Relight node, we then select Use Input 2 in the Surface Map option in the Inspector.

The surface map generated by the Surface Map node

Now that we have the node tree setup correctly, the Surface Map is generated in its node; make sure it's node cache is set to On. Then we can work directly in the Relight node and select a Directional light. Using the Relighting Map Preview checkbox and the on screen controls, we can then see exactly where the lighting effect will take place, and how it will follow the curves of the subject.



With the Relighting Map Preview box checked, you can see exactly where and how the Relight will affect the subject. Unchecking the box lets you see the final color output.

The last thing we need to do is actually create our new light properties, so by using the Primaries Wheels controls in the Relight effect, we can increase the gain and color it slightly yellow/orange and increase the saturation to mimic a golden hour sunbeam on our subject, where there was only a flat cloudy day before.

Adjusting the Primaries gain and saturation wheels in the Relight node to add the character of the light, selling the illusion that the model is leaning over the fence into a sunbeam.

Chapter 160

Resolve FX Revival

This category consists of plugins that let you fix common technical, damage, and quality problems that bedevil programs being finished, remastered, or restored.

Automatic Dirt Removal
(Studio Version Only)

The Automatic Dirt Removal plugin uses optical flow technology to target and repair temporally unstable bits of dust, dirt, hair, tape hits, and other unwanted artifacts that last for one or two frames and then disappear. All repairs are made while maintaining structurally consistent detail in the underlying frame, resulting in a high quality restoration of the image. Fortunately, despite its sophistication, this is a relatively easy plugin to use; just drop the plugin on a shot, adjust the parameters for the best results, and watch it go.

(Top) Original image, (Bottom) Using Automatic Dirt Removal

NOTE: This plugin is less successful with vertical scratches that remain in the same position for multiple frames and is completely ineffective for dirt on the lens that remains for the entire shot.

Main Controls

The primary controls used to adjust how much dirt is removed from the image.

- **Motion Estimation Type:** Lets you choose from among None, Faster, Normal, and Better. This tunes the tradeoff between performance and quality.
- **Neighbor Frames:** Lets you choose how many frames to compare when detecting dirt. Choosing more frames of comparison takes longer to process, but usually results in finding more dirt and artifacts.
- **Repair Strength:** This slider lets you choose how aggressively to repair dirt and artifacts that are found. Lower settings may let small bits through that may or may not be actual dirt, while higher settings eliminate everything that's found.
- **Dirt Size Threshold:** This slider lets you tune how large a detected bit of dirt must be to be removed. Raising this parameter lets you omit things like film grain from the operation but may allow smaller bits of dirt through.
- **Show Repair Mask:** This checkbox lets you see the dirt and artifacts that are detected by themselves, so you can see the effectiveness of the results as you fine tune this filter.

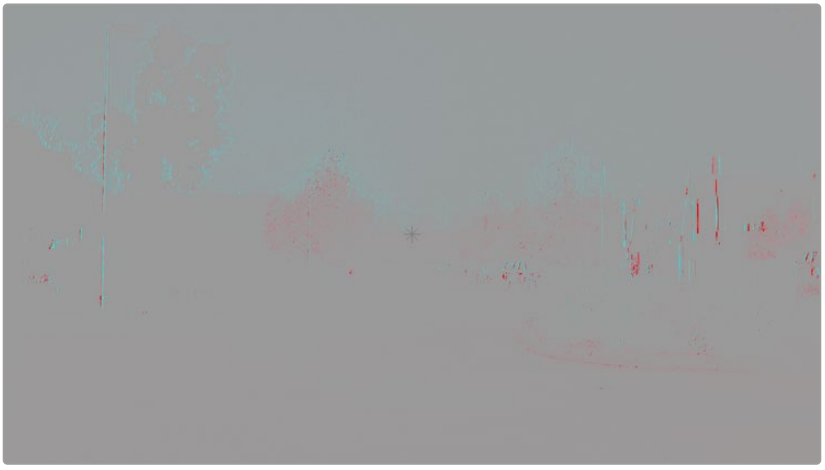
Fine Controls

These controls let you fine tune the effect in an effort to perfect the tradeoff between removing dirt successfully and preserving true image detail.

- **Motion Threshold:** This slider lets you choose the threshold at which pixels in motion are considered to be dirt and artifacts. At lower values more dirt may escape correction, but you'll experience fewer motion artifacts. At higher values, more dirt will be eliminated, but you may experience more motion artifacts in footage with camera or subject motion.
- **Edge Ignore:** This slider lets you exclude hard edges in the picture from being affected by dirt or artifacts that are removed. Higher values omit more edges from being affected.

Chromatic Aberration Removal (Studio Version Only)

A Revival category plugin that lets you manually correct the slight color fringing that results from chromatic aberration in a lens. Show Estimated Fringes checkboxes for the RGB channels display an "alignment guide" that visually isolates each of the types of fringing against gray.



(Previous page) The original image in close up, showing chromatic aberration, (Above) The image with Estimated Red Fringes enabled, letting you see the specific problems as differences between red and cyan stripes

Advanced Options

Advanced Options provide additional parameters for problem shots.

- **Lens Center:** Center X and Y parameters let you offset the center of the lens if you're dealing with a reframed and re-rendered shot. You can also drag the lens center on-screen control in the Viewer to reposition.
- **Stronger Correction:** Shows the location of image features that resemble fringing.

Estimation Options

The Estimation options are used solely to highlight and identify areas of fringing. They do not affect the final output of the image. They only become available when one of the Show Estimated Fringes boxes is checked in the Aberration Correction section.

- **R/C, G/P, B/Y Balance:** These tools adjust the incoming balance between their respective colors to better identify hard to see fringing.
- **Brightness:** Magnifies the fringe indicators that are displayed when you turn on either of the Estimated Fringes checkboxes.

Aberration Correction

These tools let you make manual adjustments to correct aberration issues.

- **R/C, G/P, B/Y Scale:** Adjust these sliders to eliminate the fringing from their respective colors.
- **R/C, G/P, B/Y Edge:** Adjust to compensate for the difference in fringing due to the curvature of the lens' edges.
- **Show Estimated Fringes:** Checking this box will show just the estimated fringes over a gray background. It will also activate the Estimation Options sliders, which will let you further highlight and identify areas of fringing.

This makes it easy to make manual adjustments to correct the problem, using the Scale and Edge controls to individually adjust Red/Cyan, Green/Purple, and Blue/Yellow fringing.

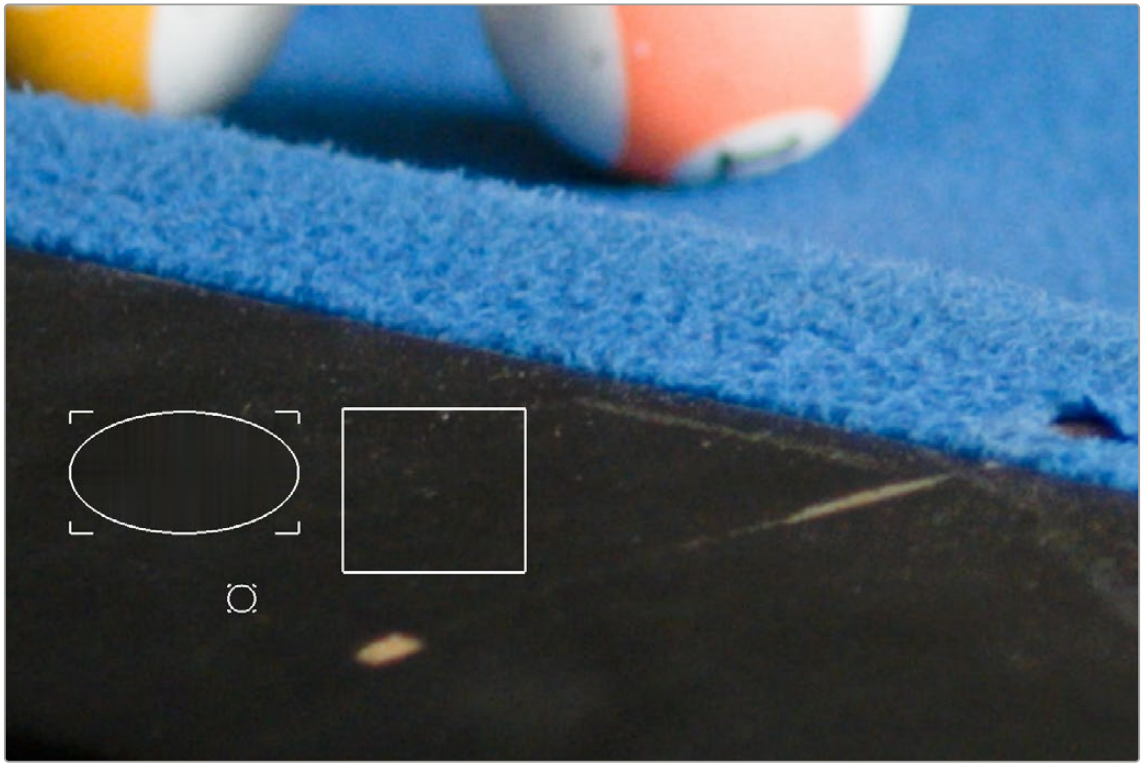
(Top) The original image in close up, showing chromatic aberration as a cyan fringe along the right of the smokestack and as a red fringe along the closest corner of the building, (Bottom) The corrected image in close up; this fringe is gone.

Dead Pixel Fixer (Studio Version Only)

If you have clips that were shot on a camera with one or more “dead” or “stuck” pixels in the sensor, you may have black or white spots that are fixed in place in the image. This filter is designed to let you place patches on each dead or stuck pixel, identifying them so you can use different methods of fixing the problem.

In many respects, the Dead Pixel Fixer is similar to the Dust Buster, however the Dust Buster effect is designed to repair transient bits of dust and dirt that only last for a frame or two, whereas the Dead Pixel Fixer is designed to work on blemishes that are fixed in place for the duration of a clip.

To fix dead or stuck pixels, apply the Dead Pixel Fixer filter, make sure the OFX onscreen controls are enabled in the viewer, and then click on each pixel you need to fix with the mouse to place a patch on it. You can click anywhere on the image to place as many patches as you like, there’s no limit. You can also Option-click to delete patches you no longer need. To move any patches, simply drag it to another location.



Multiple dead pixel removal patches

When you place multiple patches, you can click to select whichever patches you want to adjust the controls for. Each patch can have different control settings.

General

These top level controls let you choose how to draw patches with which to repair blemishes in the frame, whether or not to show their on-screen controls, and how.

- **Draw Rect:** Click and drag to place a rectangular patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
- **Draw Ellipse:** Click and drag to place an elliptical patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
- **Place Patch:** Lets you place small patches specifically for tiny details such as dead pixels. When you choose this option, a New Patch Size slider appears that lets you adjust the size of the patches you're about to place prior to placing them. Once drawn, you can click on the edge of any patch and drag to reposition it.
- **New Patch Size:** (only when Place Patch is selected) Lets you choose how large of a patch to place using the Place Patch tool.
- **Show Patches:** This checkbox lets you show or hide the onscreen outline of every patch in the Viewer.
- **Hide During Interaction :** Hides the onscreen outline of every patch in the Viewer while you're moving a patch; this makes it easier to see the effect of moving the patch on the image, without the outline getting in the way.

Patch Type

There are three methods you can use to attempt to fix the contents of a selected patch. When drawing new patches, the currently selected Patch Type will determine what the next patch will be. When you've selected an existing patch, changing the Patch Type will change how that patch works.

- **Spatial:** Automatically fills the interior of the selected patch with pixels drawn from the surroundings of the patch, using the Fill Method. This works well for small blemishes, but for large blemishes a pattern might be discernible, which gives away the effect.
- **Clone:** Clone mode copies part of the image to fill a shape or patch placed over the thing you want to remove. In this mode, clicking and dragging to place a Rect or Ellipse over an imperfection is followed by a second click to place the sample region you want to clone. Clicking once to place a Patch will be followed by a second click to place the sample region. Selecting an existing shape or patch and choosing Clone lets you click on the shape to position the clone region. The sample region is indicated by a dotted shape that's connected to the original shape.
- **Blend Clone:** Operates similarly to Clone mode, except the copied part of the image that fills the Rect, Ellipse, or Patch is blended with the image to integrate it more softly.
- **Fill Method:** When using the Spatial Patch Type, the fill method determines how the blemish in the image is repaired.

  Grid: Samples the pixels surrounding the Rect, Ellipse, or Patch, and blurs them inward both horizontally and vertically. Extremely effective for tiny blemishes. For larger blemishes, a grid-like pattern may emerge.

  Horizontal: Samples the pixels to the left and right of the Rect, Ellipse, or Patch, and blurs them inward.

  Vertical: Samples the pixels to the top and bottom of the Rect, Ellipse, or Patch, and blurs them inward.

  Patchy: Samples pixels from all around the Rect, Ellipse, or Patch, and expands and blurs them together to create a soft, non-uniform region with which to repair the blemish. Doesn't have the patterning of the grid methods of fill, but produces an extremely smooth result.

  Smooth: Simply uses a gaussian blur to repair the blemish.

Patch Options

These options let you customize the effect of a patch filling over a blemish.

- **Variability:** (Spatial patches only) Raising this parameter lets you make the Fill Method less uniform.
- **Soft Edges:** Lets you soften the edges of the patch.
- **Size Adjust:** Lets you change the size of a patch after its creation.
- **Mute:** Lets you turn a particular patch on or off via keyframing. Useful for blemishes that only show up for a few pixels of a shot.
- **Delete Patch:** Deletes the currently selected patch; you can also Option-Click any patch to delete it as well.

Advanced Controls

These controls let you customize the UI of this effect.

- **Clone Sticks to Mouse:** When enabled, drawing or placing a Rect, Ellipse, or Patch in Clone or Blend Clone mode immediately switches to positioning the sample region, making it faster to use.
- **New Patches Stay Selected:** When enabled, patches stay selected after you draw them, in preparation for further customization.
- **UI Line Thickness:** Lets you choose how thick the on-screen outlines should be.
- **Patches Stick to:** This parameter lets you deal with fixing dead pixels or blemishes on clips that have been stabilized.

  Source: Patches you place stay put, unless you apply motion stabilization to the shot, in which case the patches are transformed along with the image so they remain "stuck" to the feature in the source clip they're fixing.

  Scene: If you're eliminating a blemish on a moving subject, you can use the FX Tracker to track the thing you're fixing, so the patch follows along with it.

- **Output Mode:** This lets you see different representations of the patched effect you're creating. There are four options.

  Patched Result: The final result, with each patch repairing the blemish it's covering.

  Patch Locations: Shows a key where each placed patch is white against black.

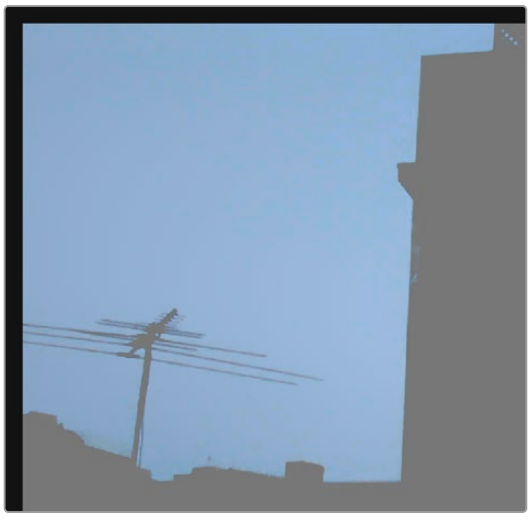
  Differences: Shows the difference of each patch against the original image.

  Difference Magnitude: Shows a more pronounced Differences representation.

Deband (Studio Version Only)

Low bit-depth media that has areas with shallow gradients of color, such as a sky or a wall, often exhibit color banding, seen as visible stripes, because there aren't enough color values to smoothly represent the gradiation from light blue to darker blue in the sky.

An example of banding in the sky of an image



Minimizing banding using the Deband filter

This filter is designed to isolate the edges of color banding and minimize them by dithering pixels from either side to soften the transition. This filter works best when applied to regions of the image that have been isolated with a secondary qualifier or window, otherwise you risk all edges within your image being dithered and thus softened (although this can be an interesting stylistic effect).

Deband Parameters

Deband controls include:

- **Edge Threshold:** Adjusts how well-defined an edge needs to be in order to be affected by this filter; lowering this excludes fainter edges, while raising this includes them.
- **Radius:** Lowers or raises the intensity of dithering in areas that will be affected.
- **Post Refine:** Narrows (by lowering) or widens (by raising) the areas affected by dithering.
- **Display Edge:** A checkbox that shows you a black and white high-contrast preview of which edges are being detected for dithering, which can help you fine-tune your results.

Deflicker (Studio Version Only)

The Deflicker plugin handles such diverse issues as flickering exposure in timelapse clips, flickering fluorescent lighting, flickering in archival film sources, and in certain subtle cases even the “rolling bars” found on video screens shot with cameras having mismatched shutter speeds. Two key aspects to this filter are that it only targets rapid, temporally unstable variations in lightness, and that it’s able to target only the areas of an image where flickering appears, leaving all other parts of the image untouched. As a result, this plugin can often repair problems once considered “unfixable.”

Original image with flicker bars in the blue screen

Result setting Deflicker to Fluoro Light, (clip courtesy Redline Films)

Main Parameters

By default, the top section of this plugin exposes a single control, which in many cases may be all you need.

- **Deflicker Settings pop-up menu:** The top two options, Timelapse and Fluoro Light, are presets that effectively eliminate two different categories of flickering artifacts. If neither of these presets is quite as effective as you’d hoped, a third option, Advanced Controls, opens up the Isolate Flicker controls at the heart of this plugin to let you tailor it further to your needs.

Temporal NR

Hidden by default, these controls only appear when you set Deflicker Setting to Advanced Controls, and let you choose how to detect motion in the scene so that flickering may be correctly addressed relative to the motion of subjects and items within the frame where it appears.

- **Frames Either Side:** Specifies the number of frames to analyze to determine what’s in motion. Higher values are not always better; the best setting is, again, scene dependent. The default is 3.
- **Mo.Est. Type:** Picks the method DaVinci Resolve uses to analyze the image to detect motion. Despite the names of the available options, which options will work best is highly scene

dependent. The default, Faster, is less processor intensive, but less accurate, however this can be an advantage and actually do a better job with high detail images that would confuse the Better option. Choosing Better is more accurate, but more processor intensive, and Better will try harder to match fine details which can sometimes cause problems. None lets you disable motion analysis altogether, which can work well (and will be considerably faster) in situations where there's no motion in the scene at all. The default is Better.

- **Motion Range:** Three settings, Small, Medium, and Large, let you choose the speed of the motion in the frame that should be detected.
- **Luma Threshold:** Determines the threshold above which changes in luma will not be considered flicker. The range is 0–100, 0 deflickers nothing, 100 applies deflickering to everything. The default is 100.
- **Chroma Threshold:** Determines the threshold above which changes in chroma will not be considered flicker. The range is 0–100, 0 deflickers nothing, 100 applies deflickering to everything. The default is 100.
- **Luma Chroma Same Threshold:** Lets you choose whether to gang the Luma and Chroma Threshold sliders or not.
- **Motion Threshold:** Defines the threshold above which motion will not be considered flicker.

Speed Optimization Options

Closed by default, opening this control group reveals two controls:

- **Reduced-Detail Motion checkbox:** On by default, reduces the amount of detail that's analyzed to detect flicker. In many cases, this setting makes no visible difference but increases processing speed. Disable this setting if your clip has fine detail that is being smoothed too aggressively.
- **Limit Analysis Area checkbox:** Turning this on reveals controls over a sample box that you can use to limit deflickering to a specific region of the image. This option is useful when:
  a) Only one part of the image is flickering, so focusing on just that area speeds the operation considerably, or
  b) Part of the image is being smoothed too much by deflickering that's fixing another part of the image very well.

Restore Original Detail After Deflicker

Closed by default, opening this control group reveals two controls:

- **Detail to Restore slider:** Lets you quickly isolate grain, fine detail, and sharp edges that should not be affected by the deflicker operation, preserving those fine details exactly.
- **Show Detail Restored checkbox:** Turning this checkbox on lets you see the edges that are detected and used by the Detail to Restore slider, to help you tune this operation.

Output

The Output pop-up menu lets you choose what Deflicker outputs, with options to help you troubleshoot problem clips. Here are the available options:

- **Deflickered Result:** The final, repaired result. This is the default setting.
- **Detected Flicker:** This option shows you a mask that highlights the parts of the image that are being detected as having flickering, to help you evaluate whether the correct parts of the image are being targeted. This mask can be very subtle, however.
- **Magnified Flicker:** This options shows you an exaggerated version of the Detected Flicker mask, to make it easier to see what the Deflicker plugin is doing.

Dust Buster (Studio Version Only)

This plugin is also designed to eliminate dust, dirt, and other imperfections and artifacts from clips, but it does so only with user guidance, for clips where the Automatic Dirt Removal plugin yields unsatisfactory results. This guidance consists of moving through the clip frame-by-frame and drawing boxes around imperfections you want to eliminate. Once you've drawn a box, the offending imperfection is auto-magically eliminated in the most seamless way possible. This works well for dirt and dust, but it also works for really big stains and blotches, as seen below.

(Previous page) Drawing a box around dirt in the original image, (Above) Result in the Dust Buster plugin

In many respects, the Dust Buster is similar to the Dead Pixel Fixer, however the Dust Buster effect is designed to repair transient bits of dust and dirt that only last for a frame or two, whereas the Dead Pixel Fixer is designed to work on blemishes that are fixed in place for the duration of a clip.

General

These top level controls let you choose how to draw patches with which to repair temporally unstable dust and dirt in the frame, whether or not to show their on-screen controls, and how.

- **Navigation Controls:** Four buttons let you jump to frames on which you've drawn patches. There are four buttons:

  First Modified Frame: Jumps the playhead to the first frame of that clip with a patch.

  Previous Modified Frame: Jumps the playhead to the last frame back with a patch.

  Next Modified Frame: Jumps the playhead to the next frame forward with a patch.

  Last Modified Frame: Jumps the playhead to the last frame of that clip with a patch.

- **Draw Rect:** Click and drag to place a rectangular patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
- **Draw Ellipse:** Click and drag to place an elliptical patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
- **Place Patch:** Lets you place small patches specifically for tiny details such as dead pixels. When you choose this option, a New Patch Size slider appears that lets you adjust the size of the patches you're about to place prior to placing them. Once drawn, you can click on the edge of any patch and drag to reposition it.
- **New Patch Size:** (only when Place Patch is selected) Lets you choose how large of a patch to place using the Place Patch tool.
- **Show Patches:** This checkbox lets you show or hide the onscreen outline of every patch in the Viewer.
- **Reset Frame:** Clears all patches from the current frame.

Patch Type

There are six methods you can use to attempt to fix the contents of a selected patch. When drawing new patches, the currently selected Patch Type will determine what the next patch will be. When you've selected an existing patch, changing the Patch Type will change how that patch works.

- **Auto:** The default method. Once you've drawn a bounding box, the two frames prior to and the two frames after the current clip will be analyzed and compared to the current image. The best of these 5 frames will be sampled to remove the imperfection in the current frame. Images two frames away are prioritized since that will avoid the appearance of frozen grain, but only if they're a suitable match to the content of the current frame.
- **+/- 1 Frame:** In this mode, if you draw a bounding box from left to right, the next frame will be drawn upon to remove the imperfection. If you draw a bounding box from right to left, the previous frame will be used.
- **+/- 2 Frames:** If you draw a bounding box from left to right, the image two frames forward will be drawn upon to remove the imperfection. If you draw a bounding box from right to left, the image two frames back will be used.
- **Spatial:** Automatically fills the interior of the selected patch with pixels drawn from the surroundings of the patch, using the Fill Method. This works well for small blemishes, but for large blemishes a pattern might be discernible, which gives away the effect.
- **Clone:** Clone mode copies part of the image to fill a shape or patch placed over the thing you want to remove. In this mode, clicking and dragging to place a Rect or Ellipse over an imperfection is followed by a second click to place the sample region you want to clone. Clicking once to place a Patch will be followed by a second click to place the sample region. Selecting an existing shape or patch and choosing Clone lets you click on the shape to position the clone region. The sample region is indicated by a dotted shape that's connected to the original shape.

- **Blend Clone:** Operates similarly to Clone mode, except the copied part of the image that fills the Rect, Ellipse, or Patch is blended with the image to integrate it more softly.
- **Fill Method:** When using the Spatial Patch Type, the fill method determines how the blemish in the image is repaired.

  Grid: Samples the pixels surrounding the Rect, Ellipse, or Patch, and blurs them inward both horizontally and vertically. Extremely effective for tiny blemishes. For larger blemishes, a grid-like pattern may emerge.

  Horizontal: Samples the pixels to the left and right of the Rect, Ellipse, or Patch, and blurs them inward.

  Vertical: Samples the pixels to the top and bottom of the Rect, Ellipse, or Patch, and blurs them inward.

  Patchy: Samples pixels from all around the Rect, Ellipse, or Patch, and expands and blurs them together to create a soft, non-uniform region with which to repair the blemish. Doesn't have the patterning of the grid methods of fill, but produces an extremely smooth result.

  Smooth: Simply uses a gaussian blur to repair the blemish.

Patch Options

These options let you customize the effect of a patch filling over a blemish.

- **Variability:** (Spatial patches only) Raising this parameter lets you make the Fill Method less uniform.
- **Soft Edges:** Lets you soften the edges of the patch.
- **Size Adjust:** Lets you change the size of a patch after its creation.
- **Mute:** Lets you turn a particular patch on or off via keyframing. Useful for blemishes that only show up for a few pixels of a shot.
- **Delete Patch:** Deletes the currently selected patch; you can also Option-Click any patch to delete it as well.

Advanced Controls

These controls let you customize the UI of this effect.

- **Clone Sticks to Mouse:** When enabled, drawing or placing a Rect, Ellipse, or Patch in Clone or Blend Clone mode immediately switches to positioning the sample region, making it faster to use.
- **New Patches Stay Selected:** When enabled, patches stay selected after you draw them, in preparation for further customization.
- **UI Line Thickness:** Lets you choose how thick the on-screen outlines should be.
- **Output Mode:** This lets you see different representations of the patched effect you're creating. There are four options.

  Patched Result: The final result, with each patch repairing the blemish it's covering.

  Patch Locations: Shows a key where each placed patch is white against black.

  Differences: Shows the difference of each patch against the original image.

  Difference Magnitude: Shows a more pronounced Differences representation.

Frame Replacer (Studio Version Only)

The Frame Replacer allows you to reuse or blend adjacent frames together to help remove any corrupt frames or artifacts that show up for the duration of just a single frame. It's useful for fixing problems like a damaged film frame or a video frame that has pixelated digital breakup.

- **Replace This Frame:** Checking this box selects the specific frame in the clip that you want to replace. This will also automatically apply a keyframe at the appropriate location in the clip.
- **Replacement Method:** Allows you to choose the method by which the new frame is created.

  From Previous: Replaces the selected frame with the one immediately before it, effectively duplicating the frame.

  From Next: Replaces the selected frame with the one immediately after it, effectively duplicating the frame.

  Blend Prev/Next: Replaces the selected frame with a blend of the frames immediately before and after it.

  Optical Flow: Replaces the selected frame using DaVinci Resolve's optical flow technology with a blend of the frames before and after it.

Noise Reduction (Studio Version Only)

Based on the Noise Reduction controls in the Color page, the Resolve FX Noise Reduction is divided into two types of GPU-accelerated noise reduction designed to subdue noise in problematic clips. Both methods of noise reduction can be used separately or together, in varying amounts depending on the needs of the particular material you're working on.

Temporal NR Controls

The Temporal NR controls analyze images across multiple frames to isolate noise from detail. Motion estimation settings let you exclude moving subjects from this operation to prevent unwanted motion artifacts.

- **Frames Either Side:** The number of frames on either side of the current frame that you want averaged to separate detail from the noise. You can choose between 0 and 5 frames. 0 applies no frame averaging; higher values apply more frame averaging, at the expense of being significantly more computationally intensive. A higher frame setting may yield a better analysis, but may also yield unwanted artifacts if there are fast-moving images in the frame. A value of 1 may yield better results for fast-moving images. If you need to use higher frame values, but see artifacts, you can also try adjusting the Motion Threshold to fix the issue.
- **Motion Est. Type:** Picks the method DaVinci Resolve uses to detect motion in the image. The default, Faster, is less processor intensive, but less accurate. Choosing Better can effectively exclude motion more accurately, but is more processor intensive. None lets you disable motion estimation altogether, resulting in the application of Temporal NR to the entire image.
- **Motion Range:** Three settings, Small, Medium, and Large, let you set the speed of motion that Motion Estimation should expect to exclude. A Small setting assumes slow-moving subjects with little or no motion blur, allowing Temporal NR to affect more of the image at a given Motion Threshold setting. A Large setting assumes fast motion with blur occupying a larger area of the image, which excludes more of the image from Temporal NR at the same Motion Threshold setting. Choose the setting that gives you the best compromise between reducing noise and the introduction of motion artifacts when adjusting the Motion Threshold parameter.

Temporal Threshold Controls

The Temporal Threshold parameters allow you to control which image characteristics get more or less noise reduction.

- **Luma Threshold:** Lets you determine how much or how little Temporal NR to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.
- **Chroma Threshold:** Determines how much Temporal NR os applied to the chroma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image. However, you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.
- **Luma Chroma Same Threshold:** Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, disabling this checkbox ungangs these parameters, allowing you to adjust different noise reduction amounts to each component of the image, depending on where the noise happens to be worst.
- **Motion:** Defines the threshold separating which moving pixels are in motion (above this threshold) versus which moving pixels are static (below this threshold). Using Motion Estimation, Temporal NR is not applied to regions of the image that fall above this threshold, to prevent motion artifacts by not applying frame-averaging to parts of the image that are in motion. Lower values omit more of the image from Temporal NR by considering more subtle movements. Higher values apply Temporal NR to more of the image by requiring faster motion for exclusion. You can choose between 0 and 100, where 0 applies Temporal NR to no pixels, and 100 applies Temporal NR to all pixels. The default value is 50, which is a suitable compromise for many clips. Be aware that if you set too high a Motion Threshold, you may see artifacts in moving parts of the image.
- **Blend:** Lets you dissolve between the image as it's being affected by the Temporal NR parameters (at 0.0) and the image with no noise reduction (100.0). This parameter lets you easily split the difference when using aggressive temporal noise reduction.

Spatial NR Controls

The Spatial NR controls let you smooth out regions of high-frequency noise throughout the image, while attempting to avoid softening by preserving detail. It's effective for reducing noise that Temporal NR can't.

- **Mode:** The Mode drop-down menu lets you switch Spatial NR between three different algorithms. All three modes of operation use the same controls, so you can switch between modes using the same settings to compare your results.

  Faster: Uses a computationally lightweight method of noise reduction that's good at lower settings, but may produce artifacts when applied at higher values.

  Better: Switches the Spatial NR controls to use a higher quality algorithm that produces greatly superior results to Faster, at the expense of being more processor intensive to render and not allowing you to decouple the Luma and Chroma Threshold sliders for individual adjustments to each color component.

  Enhanced: Does a significantly better job preserving image sharpness and detail when raising the Spatial Threshold sliders to eliminate noise. This improvement is particularly apparent when the Spatial Threshold sliders are raised to high values (what constitutes "high" varies with the image you're working on). At lower values, the improvement may be more subtle when compared to the "Better" mode, which is less processor intensive than the computationally expensive "Enhanced" setting. Additionally, "Enhanced" lets you decouple the Luma and Chroma threshold sliders so you can add different noise reduction amounts to each color component, as the image requires.

- **Radius:** Options include Large, Medium, and Small. A smaller radius offers greater real-time performance and can provide good quality when using low Luma and Chroma Threshold values. However, you may see more aliasing in regions of detail when using low NR Threshold values.

  Setting Radius to be progressively larger results in higher quality within areas of greater visual detail at high Luma and Chroma Threshold values, at the expense of slower performance. An NR Radius of Medium should provide suitable quality for most images when using medium NR Threshold settings. As with many operations, there's an adjustable tradeoff between quality and speed.

Spatial Threshold Controls

The Spatial Threshold parameters allow you to control which image characteristics get more or less noise reduction.

- **Luma:** Lets you determine how much or how little noise reduction to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.
- **Chroma:** Lets you determine how much or how little noise reduction to apply to the chroma component of the image by smoothing out regions of high-frequency noise while attempting to preserve the sharpness of significant edge details. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image. However, you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.
- **Luma Chroma Same Threshold:** Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, you can ungang these parameters to adjust different amounts of noise reduction to each component of the image.

  For example, if an image softens too much at a certain level of noise reduction, but you find more color speckling than luma noise, you can lower the Luma Threshold to preserve detail while raising the Chroma Threshold to eliminate color noise.
- **Blend:** Lets you dissolve between the image as it's being affected by the Spatial NR parameters (at 0.0) and the image with no noise reduction (100.0). This parameter lets you easily split the difference when using aggressive spatial noise reduction.

Global Blend

- **Blend:** Lets you dissolve between the image with no noise reduction (1.0) and the image with both Spatial NR and Temporal NR at their current settings (0.0).

Using Noise Reduction

The following procedure suggests a method of using the Noise Reduction (NR) parameters to achieve a controlled result.

Applying noise reduction to an image:

1. Enable Temporal NR by choosing 1 to 5 frames from the Number of Frames pop-up menu. Keep in mind that more frames dramatically increase the render time of this effect, while it may or may not significantly improve the result, depending on your material.
2. Choose options from the Motion Est. Type and Motion Range drop-down menus corresponding to how much motion is in the image. If there's a lot of motion, you may need to choose Better and Large. If there's not very much motion, lesser settings may suffice.

3 With Luma and Chroma Threshold linked, slowly raise either parameter until you just start to see a reduction in noise within nonmoving areas. Then make smaller adjustments to determine the maximum amount you can add without creating artifacts or overly softening detail.

4 If there's obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to address color speckling in the picture.

5 Suppose you're not satisfied with the tradeoff between the maximum possible threshold of noise reduction and the prevention of motion artifacts. In that case, you may want to adjust the Motion Threshold setting, lowering it to omit more of the motion from the noise reduction operation, or raising it to include more motion. If you're still not satisfied, you can also try better Motion Est. Type and Motion Range settings.

   Keep in mind that the strength of Temporal NR is to reduce noise in unmoving parts of the image. When you've achieved the best tradeoff between noise reduction in the still areas and avoidance of motion artifacts in the moving areas of the image, it's time to turn to Spatial NR to further eliminate noise throughout the rest of the picture.

6 Enable Spatial NR by raising either the Luma or Chroma Threshold parameters, which are linked by default, until you strike a suitable balance between the reduction of noise and an unwanted increase in image softness.

7 It's recommended to choose the Enhanced option from the Spatial NR mode pop-up, as it will yield the best possible results. However, this can be processor-intensive, so if you need better real-time performance, you can switch the mode to Faster and compare results.

8 If there's obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to apply more aggressive Spatial NR to address color speckling in the picture.

9 If you've had to use a high Spatial NR Luma or Chroma Threshold setting to reduce noise visibly, and areas of detail look a bit chunky or aliased, you can choose a larger setting from the Radius pop-up menu to enable a more detailed analysis of the scene.

   This will result in higher visual quality, but larger NR Radius settings are more processor-intensive and may reduce real-time performance if you don't have adequate GPU resources available to your system.

10 If you've found suitable noise reduction settings, but the result is too aggressive and makes the image appear too processed, you can try raising the Spatial NR and/or Temporal NR Blend parameters to fade between the noise reduction added by each set of controls, and the image as it was before you added noise reduction.

Try Applying Temporal NR First, then Applying Spatial NR

Because Temporal NR analyzes multiple frames for its noise isolation, it tends to be better at preserving detail accurately in regions of the image where there's little motion. If you try applying Temporal NR first and get a successful result, even if only in part of the image, you may reduce how much Spatial NR you have to apply, thus improving the overall quality of your final result.

Keep in mind that while Temporal NR does a great job in unmoving parts of an image but is less effective when dealing with subjects in motion, Spatial NR can reduce noise everywhere in the frame falling below its threshold, even when there's motion. Ultimately, a combination of the two is almost always going to be a winning combination.

Spatial NR Radius, How Large Should You Go?

Larger NR Radius settings can dramatically improve the quality of high-detail regions in shots where you're using aggressive Spatial noise reduction, but it's not necessary to always jump to the large Radius setting, which provides the highest precision. In many cases, when evaluating an image that you're applying noise reduction to, you may not be able to perceive the additional quality. You'll waste processing time on an unnecessary level of correction.

It's a good idea to evaluate the full-frame image on a large enough display to see the noise you're working on within the viewing context of the intended audience. Zooming really far into a clip while applying noise reduction may encourage you to use higher quality settings than are necessary because an excessively enlarged detail of an image lets you see subtle changes that you wouldn't notice at actual size.

Object Removal (Studio Version Only)

A Revival category plugin that's best used in the Color page, Object Removal uses the DaVinci Neural Engine to attempt to remove an object in the frame as automatically as possible. This plugin works best when removing a moving object that passes over a temporally stable background, or dirt on the lens of a shot where the camera is in motion. Smaller objects get better results than larger objects, but your results really depend on the footage. Here's a simple procedure that shows how to do this.

General

- **Show Mask Overlay:** Lets you see the actual mask used, highlighted in red, for the Object Removal.

Analysis

These controls are used to analyze the motion of the scene.

- **Scene Analysis:** Press this button to analyze the clip using the selected parameters and replace the object with the appropriate background. You will need to press this button again if you change any of the parameters in this section.
- **Assume No Motion:** If the camera has been locked off for the shot while the object moves through it, check this box to greatly simplify the background analysis.
- **Scene Mode:** Provides different methods of analyzing the scene, for improving the analysis of how the area that needs to be replaced moves, to best determine how to fill the hole left by the object being removed.

  Background: Analyzes the entire image except for the object region. Boundary analyzes the boundary area surrounding the object region. Object is for analyzing an object that moves with the background, like a sticker that's on a window while the camera moves.

  Boundary: Analyzes the boundary area surrounding the object region.

  Object: For analyzing an object that moves with the background, like a sticker that's on a window while the camera moves.
- **Analysis Boundary:** Sets the object's boundary size for analysis.
- **Show Scene Mask Overlay:** Toggles the scene mask overlay on or off, letting you see what's behind the mask.

Render

These parameters let you adjust how the Object Removal is blended into the background. The Object Removal plugin is highly footage dependent, and you won't always get a good result this easily. Problems with the result are shown via gray, either gray fringing or solid gray filling the replacement window. Gray shows you where the current settings are failing to find background content with which to fill in the patch you're removing.

- **Search Range:** If you notice while playing through the analyzed result that the object removal mask has gray fringing on some frames, you can try adjusting the "Search Range" slider, which is the distance, in frames, from the current frame that the Object Removal plugin is searching for replacement image detail.

  For example, if the Search Range is 20, it searches +/-20 frames from the current location, or 40 frames total. The allowance of 10 frames means we look at every fourth frame. You will generally get the best results for the smallest range that gives an acceptable result.

- **Blend Mode:** If the patch is successfully filled, but the result isn't blending well with the background, you can try changing the Blend mode. The default is Linear, which is a simple cloning operation, but you can also choose Adaptive Blend, which can provide better results except in certain situations where the edges of the replacement patch have a different color or brightness than the background.

Clean Plate

If you're noticing that the object removal mask is filled entirely with gray on some frames, this means that background fill couldn't be easily generated for those frames. In this case, you can try clicking the "Build Clean Plate" button.

- **Clean Plate Source:** Lets you set the source of the clean plate. Options are Gray Image, which is effectively no source; Internal, which takes a "best guess" approach to generating a background with which to fill the frame and integrates this with frames that could be successfully filled in; and External, which lets you connect your own plate from another node.
- **Build Clean Plate:** Executes the building of a new clean plate background based on the Clean Plate Source parameter set.
- **Show Clean Plate:** Checking this box lets you see behind the mask to the clean plate behind it.

To remove a moving object from a clip:

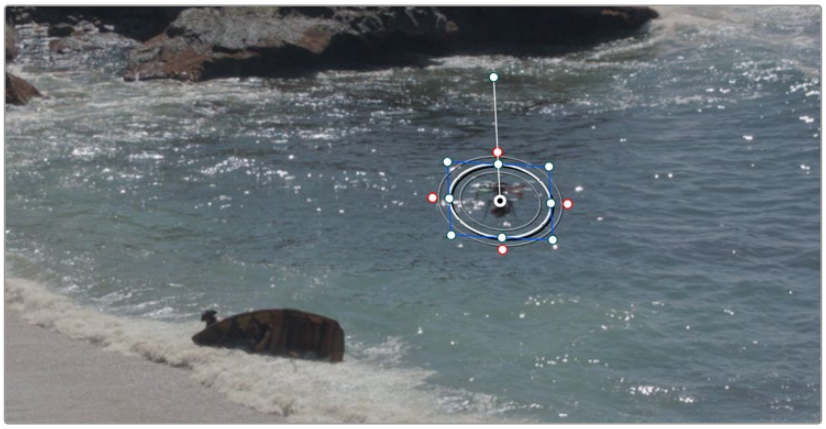
1 In this example, a drone is flying through a long shot that's being simultaneously recorded. We'll remove the drone using a window to identify the feature to be removed using the Object Removal plugin.

The original shot with a drone that needs to be removed

In simple cases, it's often easiest to apply the Object Removal effect to a Corrector node, so you can use a window or qualifier within that node to isolate the feature you want to remove. That's what we'll do in this example.

2 Use the Window palette to draw a window around the object that needs to be removed. You'll get the best results using windows or masks that hug the feature being removed fairly closely.

3 Track or keyframe the window to move with the feature you're removing. Again, you'll get better results the closer your window hugs the object being removed, and it's good to have some softness at the edge of this window.

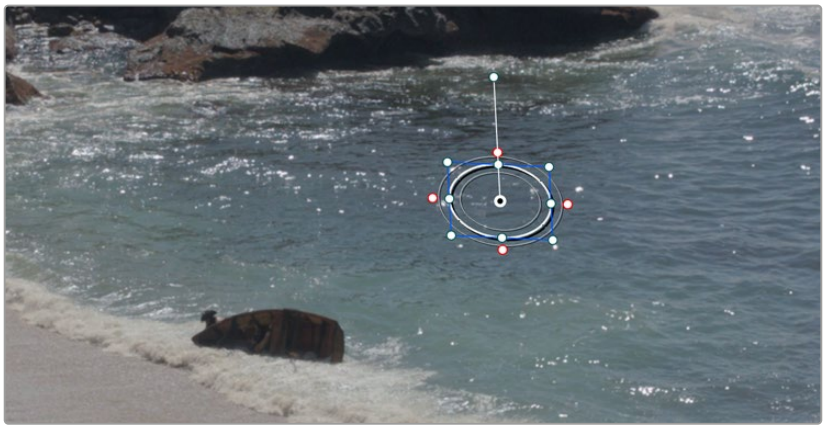


The object that needs to be removed is isolated with a window

4 Drag and drop the Object Removal plugin onto the node in which you've just isolated the feature to be removed.

5 Click the Scene Analysis button, and wait for the analysis to finish. If the object you're removing is moving but the camera is locked, you can turn on the "Assume No Motion" checkbox to improve your results in this case.

If your footage is ideal for object removal, the object will disappear once analysis is complete, replaced by a seamless background derived from detail found on neighboring frames.



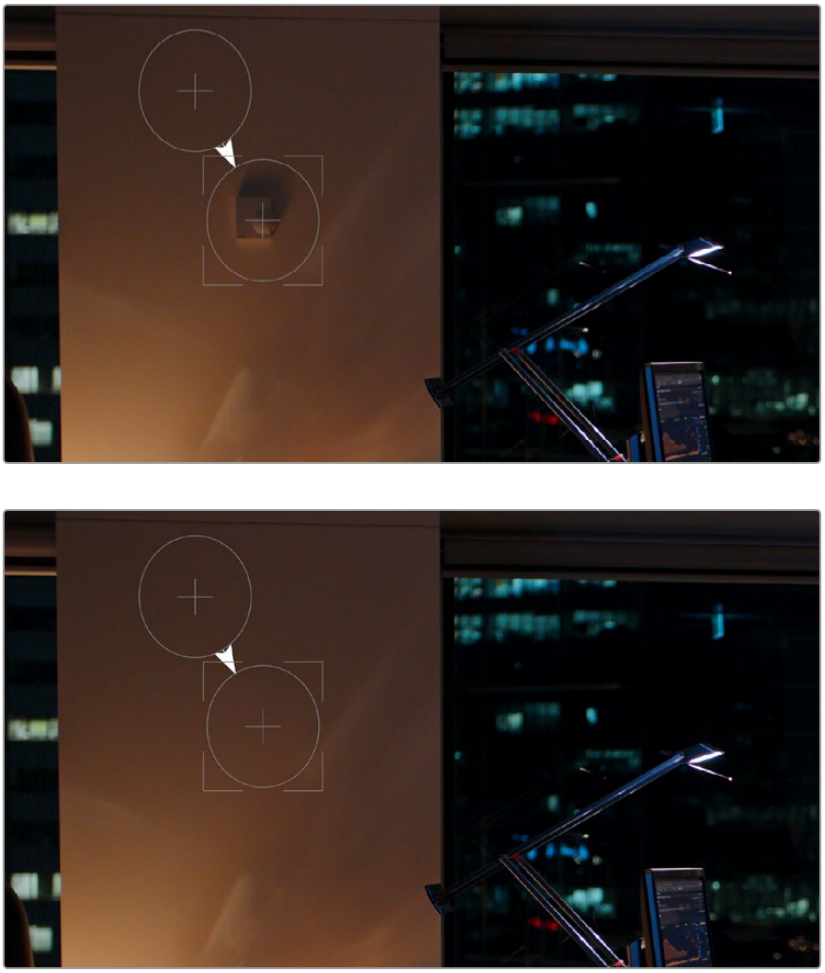
The result after object removal analysis is complete

Patch Replacer (Studio Version Only)

The Patch Replacer is a quick fix when you need to “paint out” an unwanted feature from the image. For those of you who’ve been using windows and Node Sizing to do small digital paint jobs, this plugin offers more options and a streamlined workflow.

On adding the plugin, an onscreen control consisting of two patches appears, with an arrow connecting them indicating which patch is being copied into the other. The patch behind the arrow is the “source” patch, used to sample part of the image, and the patch in front of the arrow is the “target” patch, used to cover up the unwanted feature using pixels from the source patch.

To use the Patch Replacer, simply drag the target patch over the feature you want to obscure, resize it to fit using the corner controls (the source patch is automatically resized to match), and then drag the source patch to an area of the image that can convincingly be used to fill the target patch.



(Top) Original image, (Botom) Removing the thermostat with the Patch Replacer

The source and target patches can be motion tracked using the FX tracker, so this tool is effective even if the subject or camera is moving.

Main Controls

The Fill-in Method pop-up menu is arguably the most important, as it defines what method to use to fill the destination patch with whatever is in the source patch. The rest of the primary controls work differently depending on which Fill-in method you choose.

- **Clone:** Simply copies the source patch into the target patch. When Clone is selected, the Replacement Detail slider (which defaults to 1) lets you fade out the source patch, while Region Shape lets you choose a different kind of shape to use, and Blur Shape Edges lets you feather the edge of this operation, to more convincingly blend the source with the target area.
- **Blend Clone:** A much more sophisticated method of obscuring the target area using pixels from the source patch, and in many cases will yield better results more quickly than cloning. The source patch is copied into the target patch in such a way as to combine the source detail with the lighting found inside of the target area, creating in most instances a fast, seamless match. The Keep Original Detail checkbox, when turned on, merges detail from the source and target patches to create a composite, rather than a fill. The Variability slider lets you adjust how solid the center of the patch is. The Blur Shape Edges slider works a bit differently with Blend Clone selected, but the idea is the same, feathering the effect from the outside in to obscure instances where there's a noticeable border around the target area.
- **Fast Mask:** Eliminates the source patch, doing instead a quick neighboring pixel blend that works well with small patches but can betray a grid pattern on larger patches. Region Shape and Blur Shape Edges are both adjustable.
- **Blend Mask:** Eliminates the source patch, and essentially does the Blend Clone operation but without the source. Works well on small patches, but can become too blurred on larger patch sizes. Gives you access to the Variability slider of the Blend Clone.

Patch Positions

Source X and Y, Target X and Y, and Target Width and Height are provided as explicit controls both for numeric adjustment, should that be necessary, and also to allow for keyframing in case you need to change the position and/or size of the source and fill patches over time.

Keep in mind that the source and target patches can be motion tracked using the FX tracker, although two checkboxes, Source Follows Track and Target Follows Track, let you disable FX tracker match moving when necessary.

The Align Source to Target button moves the source patch directly over the target patch, allowing you to quickly reset and iterate the location of the source patch.

Onscreen Controls

The Control Visibility pop-up menu lets you choose whether the source and target onscreen controls are visible as you work. Show (the default) leaves all onscreen controls visible all the time. Auto Hide hides all onscreen controls whenever you're dragging one, letting you see the image as you adjust it without having these controls in the way. Hide makes all onscreen controls invisible, so you can see a clean version of the image with the effect, however you can still edit the effect if you remember where the controls are.

Chapter 161

Resolve FX Sharpen

These plugins offer a newer and more detailed method of sharpening specific details in images than the sharpen operation found in the Blur palette.

Three different plugins offer different ways of using the same fundamental algorithm to perform different tasks.

Main Controls 3419
Adjust Small Skin Texture Granularity 3419

Sharpen (Studio Version Only)

The Sharpen filter functions by separating the image into four levels of detail, the underlying structure, the fine scale details, the medium scale details, and the large scale details, each of which encompasses differently sized structures that comprise the overall image. In this way, the Sharpen filter lets you apply different amounts of sharpening to each of the fine, medium, and large structures of the image, giving you enormous control over how these different structures of image detail are affected.

Main Controls

Controls the overall sharpening effect.

- **Sharpen Amount:** The primary global control that lets you add sharpening to the image. To refine the result, use the controls in Detail Levels to choose how much sharpness to apply to each size of structure this plugin can operate upon. 1.800 is the default value. 0 is no sharpening, 5.000 is maximum sharpening.

Detail Levels

Lets you customize the sharpen effect in a variety of highly specific ways.

- **Fine Detail Size:** This slider adjusts the threshold of what is considered to be a fine detail, although this also alters which image structures are affected by the Medium and Large Details sliders as well. Lowering this slider omits larger structures of the image from sharpening. The default is 0.050.
- **Fine Detail:** At its default setting, the Fine Details slider governs the sharpness of extremely fine detail such as skin pores and strands of hair, or small speckles on textured surfaces. Lower settings apply less sharpening to these structures, while higher settings apply more sharpening.
- **Medium Details:** This slider governs the sharpness of coarser detail such as freckles, wrinkles, clusters of hair, and surface details with greater edge definition. Lower settings apply less sharpening to these structures, while higher settings apply more sharpening.
- **Large Details:** This slider governs the sharpness of the largest details in the image, such as eyelids, the shadows at the edges of lips and noses, and the edges where hair meets the face, and the most contrasty edge details throughout the image. Lower settings apply less sharpening to these structures, while higher settings apply more sharpening.

Chroma

A special purpose control that you want to handle with care.

- **Sharpen Chroma:** Selectively sharpens the chroma of the image while leaving the luma (Y) alone.

Sharpen Edges (Studio Version Only)

A variation of the Sharpen filter that's streamlined for detecting edges to create a key used to limit sharpening to the selected edge details of an image. This is a good filter to use when attempting to make mildly soft-focus clips less objectionable.

Main Controls

Controls the overall sharpening effect accomplished with this plugin.

- **Sharpen Amount:** The primary global control for adding sharpening to the edges detected by this filter.
- **Sharpen Radius:** Controls the granularity of the detail that's added using Sharpen Amount.

Edge Detection Controls

These controls let you customize the sharpen effect in very specific ways.

- **Display Edges:** This checkbox lets you see a grayscale preview of the edges that are being detected for sharpening while you use the other controls in this group. If you turn this checkbox on, you can see precisely the effect that the four other controls in this section have on the key that determines which parts of the image are sharpened.
- **Pre Denoise:** Smooths the matte to remove individual pixels of noise. Reducing Pre Denoise lets you minimize edges from the key that you don't want to sharpen and soften edges that are jagged because of excessive noise. Raising Pre Denoise adds more edges to the sharpening operation and strengthens the edges that are already there.
- **Edge Detect Threshold:** Lets you adjust how strong edge detail needs to be in order to be included in the key. Reducing this parameter includes more edges in the operation, while raising it excludes edges from the operation.
- **Edge Mask Strength:** Lets you increase the intensity of the edges in the key. Reducing Edge Mask Strength diminishes the edges and reduces the intensity of sharpening in those areas. Raising Edge Mask Strength intensifies the edges and adds more of the image within the region of each detected edge to the sharpening operation.
- **Edge Blur:** Lets you control the softness of the edges in the key. Reducing Edge Blur sharpens the key and narrows the edges that are affected by sharpening. Increasing Edge Blur softens the key and potentially includes a wider area of image detail in the sharpening operation.

Soften and Sharpen (Studio Version Only)

A variation of the Sharpen filter that's streamlined for letting you both smooth some details and add sharpness to other details of the image based on the size of the structures. It can be used with any image for which you want to smooth some features while sharpening others, but this is an operation that's often used for minimizing unwanted blemishes, wrinkles, or scarring when used within a window or qualifier that's isolating the skin.

The advantage of using Soften and Sharpen is that you can use the Small Texture slider to leave a bit of natural skin detail intact, such as pores and other small naturalistic details, while you use the Medium and Large Texture controls to smooth out unwanted details in whatever proportion gives you a naturalistic result.

TIP: The best way to achieve a more natural result is to leave Small Texture at 0 or just above, while reducing Medium Texture just enough to minimize whatever details merit minimizing and reducing Large Texture by somewhat less to minimize larger blemishes, while leaving overall face detail intact. This is the logic behind the default values of Small 0.000, Medium –0.800, and Large –0.300.

Main Controls

Each of the Small, Medium, and Large Texture sliders can be moved into both negative and positive values. A value of 0 means no change is made to the corresponding details of the image. Negative values remove the corresponding details from the image, eventually leaving only the underlying smooth structure of the image at –1.000. Positive values add sharpness to the corresponding details of the image, to a maximum value of 1.000.

- **Small Texture:** Affects extremely fine detail such as skin pores and strands of hair.
- **Medium Texture:** Impacts coarser detail such as freckles, wrinkles, and clusters of hair.
- **Large Texture:** Affects the largest details in the image such as eyelids, eyebrows, the edges of lips and noses, and the edges where hair meets the face.

TIP: What's identifiable as a small, medium, or large structure depends in large part on how the subject of the shot is framed. These structures differ depending on whether you're grading a subject in a long shot (where they appear small) versus a subject in closeup (where they appear large).

Adjust Small Skin Texture Granularity

This control lets you adjust the distinction between the Small and Medium/Large texture controls in the previous group of controls.

- **Small Texture Size:** Defines the threshold that differentiates Small Textures from Medium and Large Textures, to help you fine-tune the Small Texture that you want to preserve. Raising this value includes more of the image as small details, while lowering this value excludes more of the image from small details.

Chapter 162

Resolve FX Stylize

The plugins found in this category all enable different ways of creating artistic modifications to the image.

Abstraction (Studio Version Only)

A deceptively powerful filter that lets you create a wide range of cartoon-like renders by simplifying an image into adjustable pools of similar color with optional outlines.

Main Controls

These controls create the foundation of this effect.

- **Pre Blur:** Simplifies the image by blurring unwanted details prior to this filter taking effect.
- **Abstraction Strength and Iterate Abstraction:** These parameters work together to then smooth the image, creating pools of simplified color within the details of the image.

  Abstraction Strength: Must be higher than 0 for the Iteration No. parameter to have an effect. Higher Abstraction Strength simplifies image detail even more by averaging adjacent regions of color together.

  Iterate Abstraction: Reduces the amount of small detail in the image even further by "widening" adjacent areas of similar color to blend together as one.

Quantization Controls

These controls simplify the pools of color even more aggressively by quantizing the bit depth used to stylize the image. The result is an even sharper flattening of each region of color.

- **Quantization:** A checkbox turns this function on.
- **Steps:** Raising this parameter lets you subdivide each region of color into a greater number of separate regions.
- **Softness:** Lets you blur the border between each level of color.

Draw Edge Controls

Adds an edge to the regions of color created by this effect.

- **Draw Edge:** Enables edge drawing.
- **Edge Strength:** Raising this value results in thicker and better-defined edges.
- **Edge Detection Threshold:** Raising this value restricts edges to only the boldest edge details in the picture.

Blanking Fill

This plugin is specifically designed to quickly fill black frame blanking with a stylized image derived from the clip itself, to make blanking less intrusive for viewers in documentaries and news segments. In the following example, the Blanking Fill plugin is used to add image to the left and right of "pillarboxed" standard definition 4:3 video that appears within a High Definition or Ultra High Definition 16:9 aspect ratio.

Original standard definition image

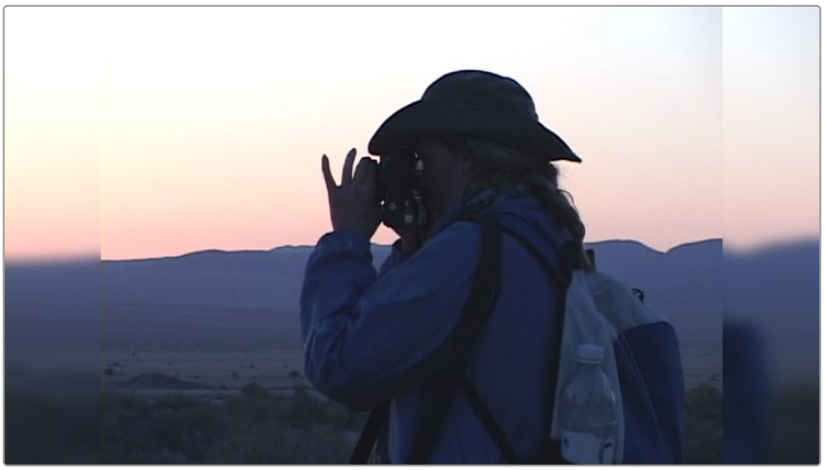

Image with default Blanking Fill applied

A variety of controls let you easily customize this effect to suit your own purposes.

Source

These controls let you transform the clip in different ways, which also affects how that clip is used to fill the blanking area.

- **Zoom:** Zooms the clip while keeping it within the native domain of definition. Good for quickly cropping unwanted pixels around the edges so they're hidden and aren't used for blanking fill.
- **Crop Left and Right:** Crops both the left and right edges of the image and increases the area at the sides with blanking fill.
- **Same Left/Right Sliders:** On by default, locks both sliders together so moving one moves the other by a mirrored amount.
- **Crop Top and Bottom:** Crops both the top and bottom edges of the image and increases the vertical area with blanking fill.
- **Same Top/Bottom Sliders:** On by default, locks both sliders together so moving one moves the other by a mirrored amount.
- **Center:** If checked, re-centers the image area if a sizing operation has offset it.

Fill Extent

These controls let you choose how the current duplicate of the image is stretched to fill the blanking area.

- **Zoom Mode:** There are three options:

  Stretch to Timeline: Automatically warps the image to stretch it to fit the full frame. Keeps features in the blanking fill area level with where they appear in the original image.

  Zoom to Timeline: Automatically zooms into the image to fit the full frame. Results in the clip looking “inset” from the blanking fill image.

  Manual: Reveals Expand and Aspect sliders that let you manually choose how much to zoom and stretch the image to fit the blanking fill area.

- **Warp Top Layer:** lets you use onscreen controls to choose a section of the edge of an image to stretch out to fill blanking in the frame. In this mode, there are two sets of onscreen controls you can use to customize the result:

  A set of outer handles let you choose how far out to warp the edges of the image to fill whatever blanking there is. These default to the project frame size.

  A set of inner handles lets you choose how much of the image you want to stretch out. These default to the current title safe boundary. If you customize these, choosing too narrow an edge results in a more extreme warping and stretching effect, while choosing a wider edge to stretch looks more natural, but affects more of the frame.

- **Expand:** (Only appears when Zoom Mode is set to Manual) Zooms the image.
- **Aspect:** (Only appears when Zoom Mode is set to Manual) Stretches the image.

The original 4:3 image edited into a 16:9 timeline with black pillar boxing to the left and right as a result

The image with Blanking Fill set to Warp Top Layer, stretching the left and right edges to fill the blanking area

Fill Appearance

These controls let you change the look of the image being used to fill the blanking area.

- **Blend Edges:** Lets you feather the edges where the original image meets the blanking fill area.
- **Blur Background:** Lets you choose how much or how little to blur the image that fills the blanking fill area.
- **Fade Amount:** Lets you fade or tint the blanking fill area. At 0, there's no fade applied. At 1.000, the blanking area is filled with a solid color defined by the Fade Color control.
- **Fade Color:** A color picker/eyedropper combination that lets you choose a color with which to fade, tint, or fill the blanking fill area.

Drop Shadow

These controls let you add a drop shadow to "lift" the foreground image against the blanking fill image.

- **Shadow Strength:** Lets you choose how solid the drop shadow appears.
- **Drop Angle:** Lets you choose the angle the drop shadow appears at. At 0 the drop shadow is centered.
- **Drop Distance:** Offsets the drop shadow farther in the direction of the Drop Angle
- **Blur:** Softens the drop shadow.
- **Color:** Tints the drop shadow.

Defocus Background

The Defocus Background effect lets you blur only the background of an image and provides a detailed set of tools to mimic shooting with a shallow depth of field.

The original image with a busy, distracting background

Using the Defocus Background effect to blur the background, making it less distracting and mimicking a shallower depth of field

The Defocus Background effect does not qualify or isolate the foreground subject. In order to use the Defocus Background, you must first isolate the foreground subject using an effect or mask using another tool like Magic Mask or a Power Window. You can then apply Defocus Background either to the same node or connect the key output from a previous node.

Connecting the key output of the Magic Mask to the Defocus Background effect; Defocus Background requires a key generated from another tool like Magic Mask or a Power Window to work.

Adjust Mask

These controls let you adjust the mask that separates the sharply focused areas from the areas you want to blur.

The Mask Preview option shows where the defocus operations will take place (black areas).

- **Mask Preview:** Checking this box will bring up a black and white preview of your mask. The white areas of the mask will stay sharp, while black areas of the mask are what will be blurred using the mask controls below. This is convenient to have up while you're perfecting the mask, then disabled to see the output of the Effects and Advanced options.
- **Mask Invert:** Checking this box will invert the mask, making the white areas black and vice-versa.
- **Mask Blur:** This control adjusts the size of the Blur around the mask, letting you smoothly blend the foreground and background together.
- **Mask Contrast:** This controls how strong the divide is between the focused and blurred regions of the matte.
- **Adjust Pivot:** This allows you to set where the divide is between the focused and blurred regions of the matte.

Effects

These controls set the main characteristics of the blurred area.

- **Blur:** This slider controls the size and how much blur to apply to the blurred area.
- **Saturation:** This slider controls the saturation of the blurred area. 1.000 (default) is full saturation. A value of 0.000 makes the blurred areas monochrome.
- **Colorize:** This slider controls the amount of color to tint the blurred areas. 0.000 is the default (no colorization).
- **Color:** This is the color picker for the Colorize operation above.

Advanced Options

These controls let you adjust some of the physical characteristics of the blurred area.

- **Blur Type:** This lets you choose the blurring algorithm used to make the blur. Either Lens blur or Gaussian blur are options.
- **Anamorphism (Lens Blur):** This slider lets you set the aspect ratio of the blur to match different lens types.
- **Highlights (Lens Blur):** Lets you adjust how the highlights of the image affect the blur, dilating or eroding the image.

Drop Shadow

Lets you add a simple drop shadow to any clip, using that clip's native or generated alpha channel to create the shape of the shadow.

- **Shadow Strength:** Lets you choose how solid the drop shadow appears.
- **Drop Angle:** Lets you choose the angle the drop shadow appears at. At 0 the drop shadow is centered.
- **Drop Distance:** Offsets the drop shadow farther in the direction of the Drop Angle
- **Blur:** Softens the drop shadow.
- **Color:** Tints the drop shadow.

Edge Detect

An edge detection effect that isolates high-contrast boundaries with options for customizing which edges create outlines. With the edges isolated, this allows you to sharpen soft clips or to create a glow around a subject.

(Top) Original image, (Bottom) Image with default edge detect applied

Main

- **Mode:** Lets you choose between RGB and Grayscale edges. RGB is the default. RGB finds edges based on color and brightness, while Grayscale detects edges based solely on brightness changes.
- **Edge color:** (only enabled if Mode is set to Grayscale) Lets you colorize the edge outlines that are generated.

Detection

These controls determine the strength and parameters of the detected edges.

- **Edge Width:** Lets you set the thickness of the resulting edges.
- **Brightness:** Lets you set how bright you want the edges to be.
- **Gamma:** Applies a gamma curve to the edge detection. A gamma below one adds brightness to mid-strength edges, making more edges “detected,” while a gamma above one darkens mid-strength edges, reducing the edges to all but the strongest detected.
- **Blur:** Softens the final result, allowing the edges to blend in more naturally.
- **Edge Mask Overlay:** This checkbox overlays the edges on top of the current frame to observe the filter’s results. Unchecking this box shows only the detected edges.

Filters

These controls determine how the edges are blended with the original frame.

- **Preprocess:** Lets you choose which method of de-noising filtering to use. The default is None.

  Filter: Reduces texture and filters out detail at the chosen Scale parameter below.

  Flatten: Flattens smooth areas of the image, leaving edges only where they divide between other flat regions in the image. The Strength parameter below controls the amount of this smoothing.

- **Half-Edges Only:** Edges are detected between regions of different brightness. This option lets you determine which side of the edge to keep. The default is None (both sides of the edge are kept).

  Keep Light Side: Edge selects only the brighter half of the edge. Useful, for example, in creating a light-wrap effect on a person's face as only the lighter (face side) of the edge is selected, limiting the increased brightness of the light wrap to the face only and not the background. The Half-Edge Gain slider allows you to further boost the brightness of the edge, separately from the main Brightness control.

  Keep Dark Side: Edge selects only the darker half of the edge. Useful, for example, in creating a glow effect on a person's face as only the darker (background side) of the edge is selected, allowing a halo to form around the face, but not on it. The Half-Edge Gain slider allows you to further boost the brightness of the edge, separately from the main Brightness control.

Advanced Options

These controls allow you to select some advanced parameters for the effect.

- **Normalize Per Frame:** Performs a brightness adjustment on each incoming frame to a consistent level, causing edges to remain visible as the scene changes brightness or flickers. Use this setting if your scene has content that has constant changes in brightness levels, otherwise uncheck this box.
- **Clamp Brightness:** Keeps the output edges from becoming too bright if the contrast of the content is too high.

For example, if you wanted to make a slight glow around the woman in the frame below using edge detect:

- Select RGB Edges, Check the Edge Mask Overlay box, and adjust the Blur to about .5 to blend them into the frame subtly.
- Next select Flatten from the Preprocess control to smooth out the fine details in the image, ensuring that only the highlights from the woman's hat, arm, and phone are detected, as well as the bright fluorescent light on the wall. These are what we want to "glow." Adjust the Strength slider to taste.
- Then select "Keep Dark Side" in the Half-Edges Only box. This ensures that the glow radiates out from the edges and not onto the woman and the light. Adjust the Half-Edge Gain slider to taste.

The shot before the Edge effect

The Edge Detect effect only on the same image with the parameters described above

The Edge Detect result; notice the glow coming from the light and around the woman's hat, arm, and phone.

Emboss

An emboss effect with several options to create different kinds of outline and emboss effects.

- **Emboss Style:** This pop-up lets you choose from among Relief, Emboss Over, Sobel, and Laplacian types of embossing.
- **Power:** Lets you adjust how pronounced the emboss effect is.
- **Angle:** Lets you choose the apparent angle at which the emboss effect is rendered.

Channels

Three checkboxes let you choose to use the Red, Green, and Blue channels to create this effect.

Mirrors

An effect that lets you reflect part of the image in any direction you like. At its simplest, this can create a split mirror effect like that found at the end of Prince's "When Doves Cry." At its most complicated, multiple reflections can be set up, to create whirling Kaleidoscope patterns in the image.

Main Controls

These controls let you choose what kind of effect this plugin has.

- **Mirror Placement:** Lets you choose different types of mirror effects including Individual (a simple reflection), Rosette, and Kaleidoscope.
- **Reflect at Borders:** Lets you add another reflection of the image whenever the angle and position of your reflection would result in offscreen black coming into the frame.

Individual Controls

When Mirror Placement is set to Individual, a series of six sets of Mirror parameters lets you add multiple mirrored edges in different combinations; by default only one is on, but you can turn more edges on to create more complicated mirror effects. Each group of Mirror parameters has the following parameters:

- **Enable Mirror:** Turns that mirror reflection on.
- **X and Y Position:** Positions the center of the mirror split reflection.
- **Angle:** Lets you adjust the angle of the seam along which a reflection will run.
- **Flip:** Flips which side of the image is reflected.

Rosette Controls

When Mirror Placement is set to Rosette, a single set of parameters creates a variety of circular patterns.

- **X and Y Position:** Positions the center of the circular rosette reflection.
- **Angle:** Lets you adjust the orientation of the rosette pattern about its center.
- **Wedge Width:** Lets you adjust the thickness of the wedges around the outside of the rosette pattern, and by extension how many wedges there will be. Thicker wedges results in fewer reflections around the rosette pattern and thinner wedges result in more reflections around the rosette pattern.

Kaleidoscope Controls

When Mirror Placement is set to Kaleidoscope, a single set of parameters lets you create a variety of kaleidoscopic images:

- **X and Y Position:** Positions the center of the mirror split reflection.
- **Center Size:** Lets you shrink or expand the cells comprising the kaleidoscopic image.
- **Angle:** Lets you adjust the angle of the seam along which a reflection will run.
- **Number of Sides:** Three sides produce a triangular pattern, while four sides produce a rectalinear pattern aligned with the currently selected angle.

Pencil Sketch in DaVinci Resolve (Studio Version Only)

A plugin with highly customizable controls for making an image look like it was drawn.

- **Color Sketch:** Check this box to toggle between a color or grayscale sketch.
- **Sketch Stroke Controls:** Parameters to control the thickness of outlines, the threshold at which they appear around objects in the frame, and their length.
- **Sketch Tone Controls:** Parameters to control how many levels of tonality are in the rendered result, and contrast controls to influence how much of the image falls into shadows, mid-tones, and highlights.
- **Sketch Texture Controls:** Parameters to apply a customizable stippled texture over the image, with a checkbox to auto animate it.

(Top) The original image, (Bottom) The image with Pencil Sketch applied

Prism Blur

Simulates flat chromatic aberration and a vignetted lens.

- **X and Y Position:** Let you change the center of the effect within the frame about which chromatic aberration is created.
- **Blur Strength:** Lets you blur the primary image.
- **Aberration Distance:** Adjusts how far the aberration effect appears from the source image.
- **Aberration Strength:** Intensifies the zoom blur used to create the chromatic aberration effect to intensify it.
- **Vignette Size:** Lets you add edge vignetting to the image; setting this to 0 removes the vignette, while 1 is the maximum size of a vignette using this filter.
- **Vignette Sharpness:** Lets you adjust the feathering of the vignette effect; lowering this value softens the edge, while raising this value sharpens, but never fully eliminates the softness from this edge. The Vignette effect is designed to fall off in a way that simulates how a lens would exhibit vignetting.

Scanlines

Simulates television scanlines, or any effect where you want alternating lines to darken the image. A variety of parameters makes this an extremely flexible effect that can be applied in numerous ways.

Appearance

Let you customize the type of scanline effect you want.

- **Line Frequency:** Lets you choose how many or few lines are superimposed on the image; fewer lines automatically space themselves to be thicker as they're uniformly distributed across the image.
- **Line Sharpness:** Lets you blur the border between each line, softening the effect.
- **Line Angle:** Lets you rotate the lines to appear at any angle; the default is 0 which results in horizontal lines.
- **Line Width:** Lets you increase or decrease the width of the blanking lines that obscure the image (which default to black but are tinted by the Color 2 parameter), thus increasing or decreasing the amount of image showing through.
- **Line Shift:** Lets you offset the lines being overlaid on the image. Animating Line Shift lets you create a rolling scanlines effect.

Color

Lets you tint and shift channels of the alternating scanlines created by this filter. Exaggerated, this can create numerous other stylistic effects.

- **Color 1 and Color 2:** Color picker and eyedropper controls that let you tint each alternating set of lines (eyedroppers let you sample a color from the RGB image being input into the current node).
- **Red, Green, and Blue Offset:** Lets you offset individual channels.
- **Scanlines Only:** Lets you see just the scanlines in isolation while you adjust them.

Composite

Lets you choose how to composite the scanlines effect against the original image.

- **Scanlines Only:** Lets you output an image consisting only of the scanlines patter you've created. Good for creating different kinds of patterned textures and mattes.
- **Composite Type:** Lets you choose which composite mode is used to blend the scanline effect into the image.

Sky Replacement

Replacing a drab, colorless sky with a more vibrant one or matching skies shot on different days are common colorist tasks that are made more efficient with the Sky Replacement effect. The benefits of using Sky Replacement instead of traditional compositing methods are a focused specific toolset allowing you to:

- Dynamically match the foreground to the brightness and color cast of the sky.
- Use Tracking options to move the sky along with the clip's camera movement.
- Add realistic computer generated sky elements, like sky color, horizon haze, clouds, and light sources.

(Top) The original bland sky, (Bottom) The image with a new better looking sky.

Selecting the Sky to be Replaced

It should be noted that the Sky Replacement effect does not do any sky selection itself, but rather takes that selection from other tools and focuses on blending the selection seamlessly with either a background plate of another sky or its own artificial sky generator. The benefit of separating the sky selection and the replacement tools is deliberate, as qualifying a sky is usually trivial, while getting a good mask at the horizon is not. This allows the colorist to use the right qualifier (HSL, Window, Magic Mask, etc.) for the particular scene, and then pass that on to the Sky Replacement effect. Another benefit of this arrangement is that the Sky Replacement effect can be applied to the same node as your qualifier, letting you select and replace the sky all in one node, and both tools can be updated concurrently as you use them.

To select the sky to be replaced and connect it to the Sky Replacement FX:

1. In a color node, use any Qualifier (Power Window, HSL, 3D, Magic Mask, etc.) to get a clean key of the sky and horizon.
2. Then drag the Sky Replacement effect from the Effects Library onto the same node.
3. Or create a new color node, drag the alpha output from the previous node (blue square), to the alpha input of the new node (blue triangle), and drag the Sky replacement effect from the Effects Library to the new node.

Selecting the Replacement Sky

Once your original sky is qualified, you have two choices on what to replace the sky with, either an artificially generated sky (created in the Sky Replacement Parameters below), or new footage of a previously shot sky as a background plate.

To connect a sky background plate to the Sky Replacement FX:

1. In a color node, qualify the sky and add the Sky Replacement FX.
2. Right-click on the node with the Sky Replacement FX, and select Add OFX Input from the drop-down menu. An additional color and alpha input appear on the node.
3. Drag the clip of the sky background plate from the Media Pool into the Node tree to make a new external matte of the clip.
4. Add a serial node off the external matte to make a new color node, so you can reposition and grade the sky background plate as necessary.
5. Connect the color output of the new color node (green square) to the Sky Replacement color input (the lower green triangle on the node). This will now use the video of the background plate for the sky replacement.

The node tree showing how to add your own sky background plate footage to the Sky Replacement effect.

Sky Mask Adjustments

These options let you make final adjustments to the source mask from whatever qualifier you've used.

- **Preview Mask:** Check this box to see the mask as a black and white matte; white is where the new sky will come through.
- **Shift Edge:** Shifts the mask boundary into, or away from, the horizon.
- **Refine:** Adjusts the mask boundary to the image edges.
- **Black Level:** Adjusts the transparency level of the mask.
- **White Level:** Adjusts the opacity level of the mask.

Source Sky Appearance

These tools let you customize the look of the new incoming sky. They have no effect on the artificial sky, but only on a video clip used as a sky background plate.

- **Color Space:** Lets you adjust the incoming sky's color space. Defaults to timeline settings.
- **Gamma:** Lets you adjust the incoming sky's gamma. Defaults to timeline settings.
- **Detail:** Lets you adjust the incoming sky's midtone detail.
- **Brightness:** Lets you adjust the incoming sky's brightness.
- **Saturation:** Lets you adjust the incoming sky's saturation.
- **Temperature:** Lets you adjust the incoming sky's color temperature.
- **Tint:** Lets you adjust the incoming sky's tint.
- **Opacity:** Lets you adjust the incoming sky's opacity, if you want to blend it in with the sky from the original footage.

The same car shot with a more dramatic storm footage used as the replacement sky, adjusted with the Source Sky Appearance tools.

Artificial Sky

These options let you generate realistic looking artificial sky elements. They are broken into three categories: Sky, Cloud, and Hotspot (stand in for the sun or moon). By default, the opacities for these elements are all set to zero (off). In order to see them, you must increase the opacity for each category to a positive number.

- **Preview Artificial Sky:** Checking this box shows all the Artificial Sky categories alone, without being composited with the foreground plate.

- **Sky Opacity:** Lets you adjust the opacity of the sky. Zero is totally off, and one is completely opaque. Any value in between is used to blend the artificial sky in with the source sky.
- **Sky Color:** Lets you set the color of the sky.
- **Horizon Color:** Lets you set the color of the horizon haze that blends with the sky color.
- **Horizon Softness:** Lets you adjust how soft the horizon blends into the sky.
- **Horizon Height:** Lets you set how high the horizon reaches in the frame.
- **Horizon Angle:** Lets you adjust the angle of the horizon.
- **Cloud Opacity:** Lets you adjust the opacity of the clouds in regards to the sky. Lower values blend the clouds in more; higher values make them stand out.
- **Cloud Color:** Lets you set the color of the clouds.
- **Cloud Scale:** Lets you set the size of the noise pattern that creates the clouds, letting you choose how close the clouds are to the foreground.
- **Cloud Shape:** Lets you adjust the horizontal/vertical ratio of the clouds. Lower values equal puffier (cumulus) clouds, while higher values make them more lengthened (cirrus).
- **Cloud Tilt:** Lets you adjust the angle of the sky relative to the ground, to match the foreground angle.
- **Cloud Detail:** Lets you determine the ratio of large to fine detail in the clouds.
- **Cloud Fill:** Lets you adjust the amount of cloud cover in the sky.
- **Cloud Contrast:** Lets you adjust how contrasty the cloud cover is compared to the sky.
- **Cloud Time:** Lets you change the noise pattern of the clouds. Using this control with keyframes will let you change the cloud pattern over time.
- **Hotspot Brightness:** Lets you adjust the intensity of the hotspot. Zero is no hotspot. There is an on-screen control for this option in the Viewer.
- **Hotspot Color:** Lets you adjust the color of the hotspot.
- **Hotspot Position:** Lets you adjust the position of the hotspot. There is an on-screen control for this option in the Viewer.
- **Hotspot Size:** Lets you adjust the size of the hotspot.
- **Hotspot Sharpness:** Lets you adjust the sharpness of the edges of the hotspot.

Sky Position

These tools let you track the motion in the foreground clip, in order to realistically move the sky along with any camera movement.

- **Match Motion:** Lets you choose which tracking method to use.

  Keyframing Only: Lets you manually adjust the sky movement by keyframing the position controls.

  Track Foreground: Automatically performs a track based on the foreground elements in the composite.

  Track Original Sky: Automatically performs a track based on the sky in the original clip. Only works when the sky has existing details like clouds. This is the best and most reliable tracking method to use if your footage allows.

  Use FX tracker: Links to the track generated by the FX tracker in the tracker controls.

- **Adjust Size:** Lets you adjust the size of the sky, so that it can cover the range of motion defined in the tracker.
- **Adjust Position:** Lets you manually adjust the X and Y positions of the sky.
- **Auto-Size for Motion:** Analyzes the track and automatically sets the size and position of the sky to encompass the track's extents.
- **Flip Horizontal:** Flips the sky on its horizontal axis.

Sky Integration

These controls help you match the attributes of the final sky to the foreground footage.

- **Preview Final Sky:** Check this box to view only the final sky output, including motion and any keyframed parameters.
- **Lens Distortion:** Adjust this to warp the sky to match the curvature of the original camera lens.
- **Lens Defocus:** Adjust this to move the sky out of focus and match the depth of field of the original lens.
- **Exposure:** Lets you adjust the overall brightness of the sky.
- **Add Grain:** These controls are a simplified set of tools to emulate the grain patterns found on motion picture film. Check this box to turn the grain pattern on or off.

  Grain: Determines the amount of grain to add in the sky.

  Size: Determines the size of the grain in the sky.

  Softness: Determines how crisp the individual grains are.

  Saturation: Adds color to the grain. 0 is monochromatic.

Foreground Appearance

Turning on these controls automatically attempts to adjust the overall look of the foreground, based on an analysis of parameters of the final sky.

- **Adjust Foreground:** Check this box to activate the Foreground Appearance tools below.
- **Auto Adaptation:** Selects the method by which the Foreground Appearance analysis is generated.

  None: No automatic settings are applied. You can manually adjust the parameters below.

  Globally Applied: The color cast is calculated from the visible sky and then applied globally to the foreground, with no variations in brightness. However, the color cast will update dynamically if the sky changes over time.

  Match Horizon: The color cast is calculated from the visible sky but is weighted towards the horizon, its distance set with the Localization control. This will make brighter/darker areas of the sky apply bright/darker changes to the foreground. For example, if you have a dark sky but a moon on the horizon, the foreground will be brighter around the moon than elsewhere. This also updates dynamically over time.

- **Adaptation Amount:** Lets you select how much adaptive color adjustment to make.
- **Localization (Match Horizon only):** Lets you determine how far or near the color cast reaches from the horizon.
- **Brightness:** Lets you adjust the foreground's gain or brightness.
- **Saturation:** Lets you adjust the foreground's saturation.
- **Temperature:** Lets you adjust the foreground's color temperature.
- **Tint:** Lets you adjust the foreground's tint.

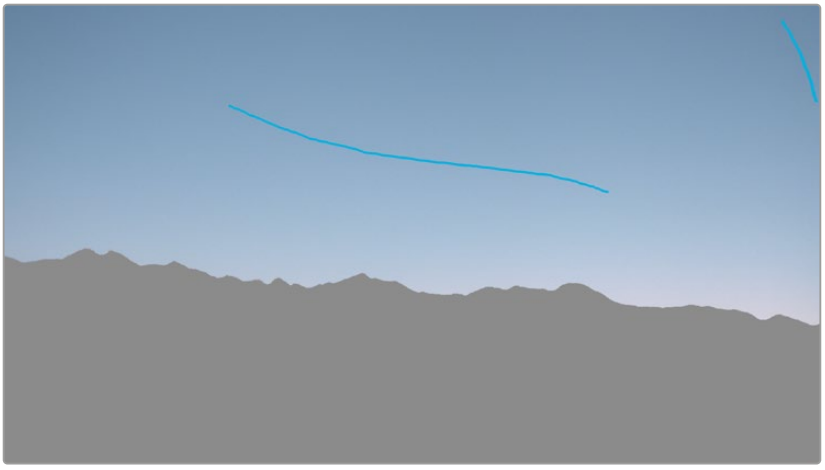
Sky Replacement Workflow

Here's a sample workflow for replacing the sky with one generated by the artificial sky tools.

This is the original clip, with the sky we want to replace. To start with, we simply make a new color node.

The original shot we want to replace the sky on.

Next we need to qualify the sky. For this clip, we can apply the Magic Mask (object) tool to the node to select just the sky we want to replace. You could also use the HSL qualifier, 3D qualifier, or even a power window to do the same thing.

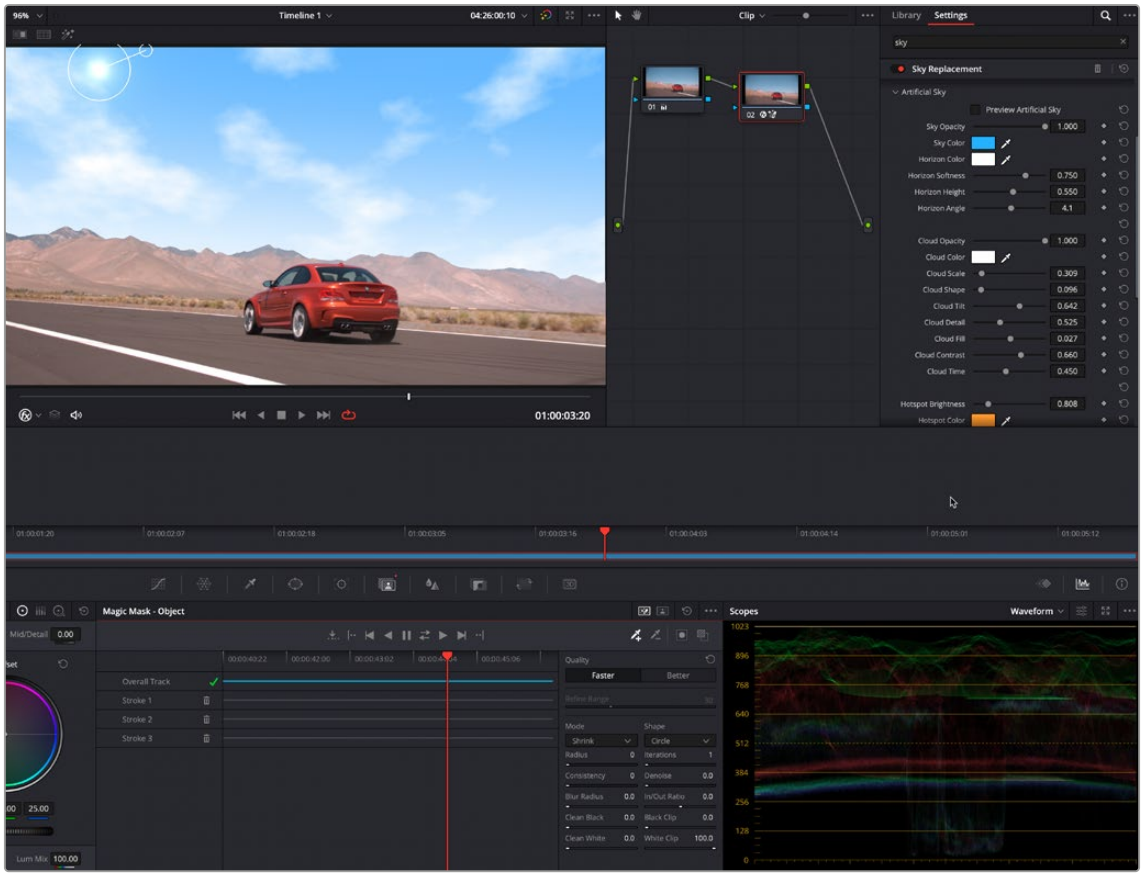


The sky qualified using the Magic Mask tool.

Now that the sky is selected, we can drag and drop the Sky Replacement effect from the Effects Library onto the same node that our Magic Mask is on.

The black area is where we will create our new sky.

Now that both toolsets are active on the same node, we can adjust both the Magic Mask and the Sky Replacement parameters at the same time. This makes the complete sky replacement a one node process.



You can use both the Magic Mask (or any qualifier) and the Sky Replacement tools on the same node.

Using the Artificial Sky Controls, we can create a new, more interesting sky. Then, using the Sky position tools, we can track the sky to the camera movement of the original clip. Finally, adding the Foreground Appearance toolset, we can seamlessly blend the foreground and sky together.

The final replaced sky that tracks with the camera movement.

Stylize (Studio Version Only)

A plugin that lets you apply one of a variety of painterly styles to an image based on analyses of different paintings, in such a way as to provide a temporally stable result for moving images as the style strokes will appear to be applied to individual objects in the scene that move and flow in a consistent way. There are two controls:

- **Styles:** A pop-up menu lets you choose an artistic style to apply to the image.
- **Style Scale:** This slider lets you adjust how large or small the applied art strokes should be applied.

(Top) The original image, (Bottom) The image with Style Transfer applied and set to Dance with a Style Scale of 4

TIP: This plugin is more flexible than you think, if you apply Style Transfer in a layered way against the original image. You can do this using a duplicate layer in the Edit page, or using two nodes representing the Style Transfer effect and original image connected with a Merge node in the Fusion page or a Layer node in the Color page. Once that's set up, simply combine the Style Transfer output with the original image using composite modes and opacity adjustments for more sophisticated blending. In particular, using the Luminosity composite mode lets you combine the texture from the Style Transfer while retaining the color of the original image, or using the Saturation composite mode lets you combine the color from the Style Transfer while retaining the texture of the original clip.

Tilt-Shift Blur (Studio Version Only)

Simulates depth-of-field effects using a progressive blur that's applied with a generated Z-depth map. The default settings create a "miniaturization" illusion, where the image appears to be tiny due to the top and bottom depth-of-field settings used.

Main Controls

These controls select and control the overall effect.

- **Blur Type:** You can choose between Fast Blur and Lens Blur (Lens Blur is the default).
- **Blur Strength:** A slider lets you adjust the amount of blur you add.

Lens Iris

The Lens Iris controls are only available when Blur Type is set to Lens Blur. This is a simplified set of controls from those of the Lens Blur filter.

- **Iris Shape:** Lets you choose what type of apertures you want to use, with which to influence the shape of the bokeh effect. Aperture Shape options include Triangle, Square, Pentagon, Hexagon, Heptagon, or Octagon shaped aperture.
- **Blade Curvature:** (Only available with Real and Creative Apertures) Lets you round off the edges of the Aperture Shape you selected.
- **Rotation:** Lets you adjust the angle the shape appears at.
- **Anamorphism:** Lets you adjust the aspect ratio of this effect in order to match the lens blur created by anamorphic lenses.
- **Highlights:** Lets you adjust how the highlights of the image affect the blur, dilating or eroding the image more or less depending on how high Smooth Strength is.

Depth of Field

Additional Depth of Field settings let you adjust the depth map being used to create the depth-of-field effect.

- **Map Source:** Lets you choose the source for the depth map. Custom (default) lets you create the depth map in the effect. From Alpha In and From Second Input allow you to import depth maps created in other nodes.
- **Center X, Center Y, and Angle:** These parameters let you transform the depth map.
- **Focus Sweep:** Lets you dial in a region based on "distance" for isolation. White areas of the depth map are affected by the blur, while black areas of the depth map are ignored.
- **In Focus Range:** Lets you expand or contract the black center of the depth map that defines the blurred region.
- **Near Blur Range and Far Blur Range:** Two parameters let you individually adjust the falloff of the white bottom and top of the depth map.
- **Depth Map Preview:** This checkbox lets you see the grayscale depth map directly while making these adjustments. The white area will be blurred, while the black area will be unaffected.

TIP: To create more believable Depth of Field adjustments, use the Depth Map effect in conjunction with the Tilt-Shift Blur effect. You can feed the results of the depth map directly into the Tilt-Shift Blur effect as a blur map, by connecting the key output of the Depth Map node to the key input of the Tilt-Shift Blur node, and selecting “From Alpha In” in the Map Source dropdown in the Depth of Field section of the effect. From there adjust the Focus Sweep to dial in the area you want to isolate. If you’re not getting the expected results, try inverting the depth map.

Watercolor (Studio Version Only)

A variation on the Abstraction filter, this filter reduces images into simplified washes of softly blended colors, in a very painterly fashion.

- **Channels:** This pop-up menu lets you choose whether to use Luminance or RGB to derive the smoothed color from.
- **Show Gradient:** This checkbox lets you see the boundaries that define each area of smooth color, based on the value you choose from the Smoothness slider below.
- **Smoothness:** Adjusts the amount of detail in the final result. Low smoothness values result in more detail in the smoothed result, while higher values result in larger pools of lower detail yet smoother color.

Chapter 163

Resolve FX Temporal

DaVinci Resolve comes with several Resolve FX that focus on the application of an effect over time.

Contents

Motion Blur (Studio Version Only) 3444
Motion Trails (Studio Version Only) 3444
General 3444
Advanced Options 3444
Move Trail 3445
Smear (Studio Version Only) 3445
Stop Motion 3446
Advanced Options 3446

Motion Blur (Studio Version Only)

This effect replicates the Motion Blur panel in the Color page's Motion Effects palette. The Resolve FX version allows you to use these tools across the other pages in the program. Motion Blur settings use optical flow-based motion estimation to add artificial motion blur to clips that have none. This can be useful in cases where a program was shot using a fast shutter speed, and you later decide that the resulting video has too much strobing. By analyzing the motion within a clip, the Motion Blur settings can selectively apply blurring to the image based on the speed and direction of each moving element within the scene.

Three parameters let you set how much motion blur to add, and at what quality:

- **Motion Est. Type:** A setting of Better provides more accurate pixel mapping at the expense of being more processor intensive. Faster provides a more approximate result but is less processor intensive.
- **Motion Range:** Determines what speed of motion to consider when defining regions being blurred.
- **Motion Blur:** Raise this parameter to add more motion blur to the image, lower it to add less. The range is 0–100, where 0 applies no motion blur, and 100 applies maximum motion blur.
- **Blur Direction:** Allows you to chose which way the blur extends from the current frame. The options are: Both Directions, From Previous Frame, and Towards Next Frame.
- **Granularity:** Adjusts how much detail is added to the blur.

Motion Trails (Studio Version Only)

The Motion Trails effect copies the image to create ghost-like trails on moving images. This effect can be used to simulate clips shot with long shutter speeds and analog video feedback effects.

General

The first two sliders control the number and strength of the copied frames.

- **Trail Length:** Determines the number of copies that are used to create the trails.
- **Dropoff:** Sets the fade applied to each copied frame. The Dropoff value is compounded. For instance, using a value of .5 applies 50% opacity to the first copy, 25% to the second, 12.5% to the third, and so on.

Advanced Options

The advanced options are used to control how the overlapping copied frames are blended.

- **Composite Gamma:** The Composite Gamma menu provides four options for controlling the brightness of the overlapping frames.

  Timeline: Uses the Timeline Color Space setting in the Project Settings to control the overlapping brightness. This setting, by default, is Rec. 709, Gamma 2.4.

  Rec. 709: Uses a Rec. 709 color space with Gamma 2.2 to control the overlapping brightness.

  Linear: Uses Linear Gamma, often producing much stronger highlights.

  Custom: Provides a custom gamma slider which defaults to Gamma of 2.4. Setting this to a value of 1.0 is the same as setting the menu to Linear.

- **Input Alpha:** The choices in the Input Alpha menu determine how the Alpha channel is used for blending the frames. All options assume there is an Alpha channel present on the clip that has the Motion Trail applied.

  Ignore: This is the default option and will cause the alpha channel to be ignored. Disabling the Use Alpha checkbox when Ignore is selected will cause the Alpha to act as a stencil effect for the trails.

  Use in Compositing: This option uses the Alpha channel for the trails and compositing over the lower video track, assuming the Use Alpha checkbox is enabled.

Move Trail

This group of controls determines the offset, direction, size, and rotation of the copies. Adjustment amounts are applied as offsets from one copy to the next. For instance, if rotation is set to 5 degrees, the first trail copy is rotated 5 degrees, the second trail copy is rotated 10 degrees, the third copy is rotated 15 degrees, and so on.

- **Pan:** Adjusts the offset of the trail copies from the original image.
- **Pan Angle:** Changes the angle at which the trails are offset from the original image. The values are shown in degrees.
- **Zoom:** Adjust a scale adjustment, successively, to each copy.
- **Rotate:** Applies an angle of rotation, successively, to each copy.
- **Reuse Current Frame:** When this checkbox is disabled (the default), each copy uses the frame after the copy before it. For instance, the first copy is the current frame -1, and the second copy is the current frame -2. When this checkbox is enabled, all copies use the same frame as the current frame in the clip.
- **Border Type:** This menu determines how edges of the frame are handled when the copies are scaled smaller than the timeline resolution.

  Black: The area outside the image is set to black.

  Soften: This control blends the edges of the rectangular frame borders to give the images a more organic appearance.

  Replicate: Duplicates the outermost pixels along the edge of the image. The pixels are stretched out from each side to reach the timeline resolution boundary.

  Reflect: The image is flipped and flopped to create a mirrored image that extends to the timeline resolution frame boundary.

  Wrap-Around: Duplicates the image to create a video wall effect, used to fill in the space to the timeline resolution frame boundary.

Smear (Studio Version Only)

The Smear effect simulates motion blur in a clip by blending a user-definable number of frames.

- **Frames Either Side:** Determines the number of frames that are blended on either side of the current frame. For instance, entering a value of 2 uses two frames before and two frames after the current frame to create the effect.
- **Luma Threshold:** This control sets how bright a pixel must be to contribute to the smear effect. A lower value causes only darker pixels to be smeared. A higher value includes brighter pixels in the effect.
- **Chroma Threshold:** This control sets how saturated a pixel must be to contribute to the smear effect. A lower value causes only low saturated pixels to be smeared. A higher value includes more saturated pixels in the effect.

Stop Motion

This plugin is used to replicate the stuttering motion effect found in stop motion animations. Traditional stop motion animation exposes each frame of the shot individually, while the subject is manually moved in tiny increments between frames. An extremely labor intensive process, often individual frames were repeated in a shot to speed up the production which resulted in a staccato motion cadence.

Advanced Options

- **Set Reference Frame:** Selects the current frame in the Viewer as the reference frame.
- **Reference Frame:** The frame number of the reference frame used for the skip pattern. The frame number is calculated from the start of the entire original media clip (frame 0).
- **Sampling Variation:** This slider increasingly produces more uneven motion in the clip.
- **Frame Repeat:** Selects how many frames (from 1-10) to duplicate in the shot. A larger number makes a more staggered cadence.

Chapter 164

Resolve FX Texture

These plugins are designed to add texture to images, to replicate both naturalistic and other effects.

Analog Damage (Studio Version Only)

A Texture category plugin that simulates different kinds of signal degradation resulting from analog transmission and recording, Analog Damage can be used to create “old TV” or “junky videotape” effects of various kinds. A Preset pop-up menu lets you choose from a variety of different looks, while a Custom option lets you create your own.

(Top) The original image, (Bottom) The image with Analog Damage applied

- **Preset:** Lets you add a number of video damage types to your footage that DaVinci Resolve was designed to repair in the first place.

  It has the following categories of parameters:

- **Telecine Source:** Options for lens vignetting and automated shutter weave to the left and right.

  Vignetting: Darkens the image around the edges to replicate a poor lamp in a telecine.

  Vignette Aspect: Adjusts the width of the vignette effect.

  Shutter Weave: Replicates the slight movement of the image as the film reel unwinds on a telecine.

- **Broadcast Signal:** Options for customizable noise, detail loss, signal ghosting, and chroma misalignment.

  Noise Scale: Determines how fine the noise is.

  Signal Noise: Determines how much static is in the Luma signal.

  Chroma Noise: Determines how much static is in the Chroma signal.

  Detail Loss: Determines how much of the detail is lost in “transmission.”

  Chroma Detail Loss: Determines how much of the chroma detail is lost in “transmission.”

  Ghosting: Replicates the ghost image due to a reflected signal.

  Ghost Offset: Lets you reposition the ghost image.

  Chroma Misalignment: Determines how offset the color signal is from the brightness.

- **Color Dials:** Television-signal specific color adjustment controls.

  Brightness: Replicates a consumer television brightness control knob.

  Contrast: Replicates a consumer television contrast control knob.

  Color: Replicates a consumer television color (saturation) control knob.

  Tint: Replicates a consumer television tint control knob.

- **Scan:** Controls to simulate problems with television scanning.

  Image Aspect: Adjusts the shape of the frame, padding or cropping as necessary.

  H-Shift: Lets you roll the image horizontally.

  V-Shift: Lets you roll the image vertically.

  V-Hold/Latch: V-Hold interacts with the V-Hold Latch parameter to make it easy to use simple key framing to trigger animated vertical rolls that “bounce” over time in a realistic way for broadcast.

  Overscan: Allows you to adjust how much of the image is cropped for display on the screen.

  V-Scale: Lets you adjust the vertical scaling of the image.

  Vertical Blanking: Lets you determine the Vertical Blanking Interval size.

- **Scan lines:** Simulate customizable television scan lines that are capable of simulating moire and color artifacts.

  Line Sharpness: Lets you adjust the visible sharpness of the scan lines.

  Line Frequency: Lets you adjust how many scan lines are in the image.

  Colored Lines: Check this box to add color outlines to the scan lines.

- **TV Construction:** Controls to simulate issues with CRT phosphor brightness, tint, and defocus, and the ability to add a customizable curved border and warped screen curvature.

  Phosphor Brightness: Lets you adjust the brightness of the front screen, even when the tv should be “off.”

  Phosphor Tint: Lets you adjust the color of the front screen, even when the tv should be “off.”

  Defocus: Lets you adjust how much detail is lost to the screen.

  Screen Curvature: Lets you adjust how curved the picture tube is.

  Edge Mask: Check this box to add a black mask around the edge of the screen.

  Edges Transparent: Check this box to make the screen edges transparent for compositing.

  Mask Curvature: Lets you adjust the shape of the black mask.

  Mask Aspect: Lets you adjust the black mask’s aspect ratio.

- **VHS:** Lets you add a customizable “Restless Foot” to simulate recorded tape artifacts.

  Restless Foot Height: Lets you set how much restless foot intrudes from the bottom of the screen.

  Restless Foot Offset: Lets you choose which direction and how much to distort the restless foot.

  Restless Foot Jitter: Lets you adjust the shaking of the restless foot between frames.

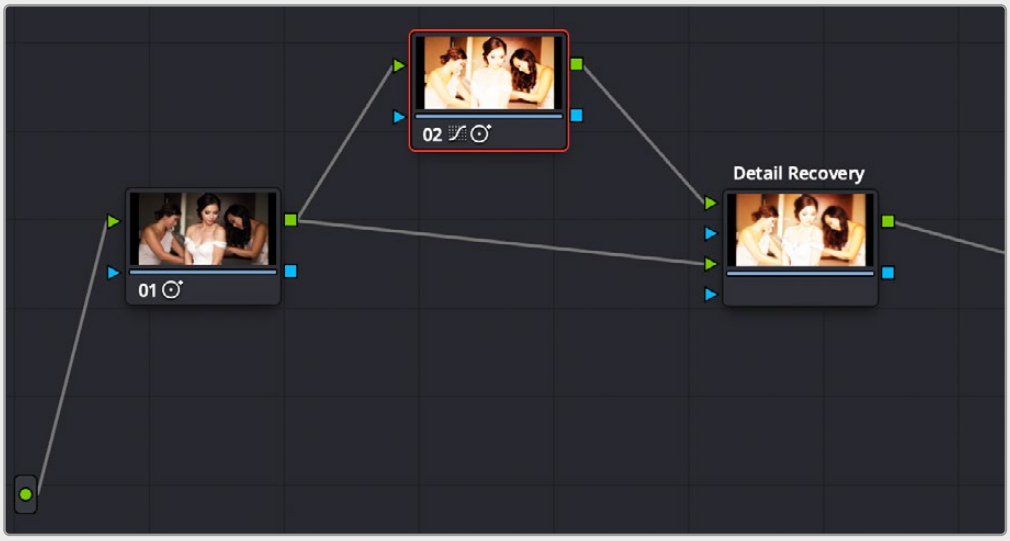
TIP: Using the Analog Damage plugin on the Fusion page makes it possible connect Modifiers to add automatic animation (such as Perturb) to different parameters in order to quickly and easily create automated video damage effects.

Detail Recovery (Studio Version Only)

Detail Recovery is a utilitarian effect that lets you extract image detail from the second input, in order to re-add it to the image coming in the first input. In this way, you can selectively add detail back to an image in which it’s been removed. Because of how it works, this is an effect that’s intended to be used on the Color page.

To use Detail Recovery, you must add it to the node tree as a Resolve FX node (dragging it directly from the Open FX library into the node tree as its own node), in order to expose both of the RGB inputs that appear on the node when you do this. By default, the first RGB input is for the image you want to add detail to, and the second RGB input is for the image you’re extracting image detail from.

In the following example, Node 1 is the base grade, and Node 2 is a grade in which the highlights are being blown out for stylistic effect. The Detail Recovery node is then being added to add specific image detail from Node 1 back to the output of Node 2.



Setting up the Detail Recovery effect to add image detail from Node 1 to the image coming from Node 2

The result, compared with the image in Node 2, is an image that’s still harshly exposed, but that has traces of fine image detail so it doesn’t look so clipped.

(Top) The image with highlights compressed harshly, (Bottom) The image with high-frequency detail added back

Detail Recovery has the following parameters.

Detail Recovery

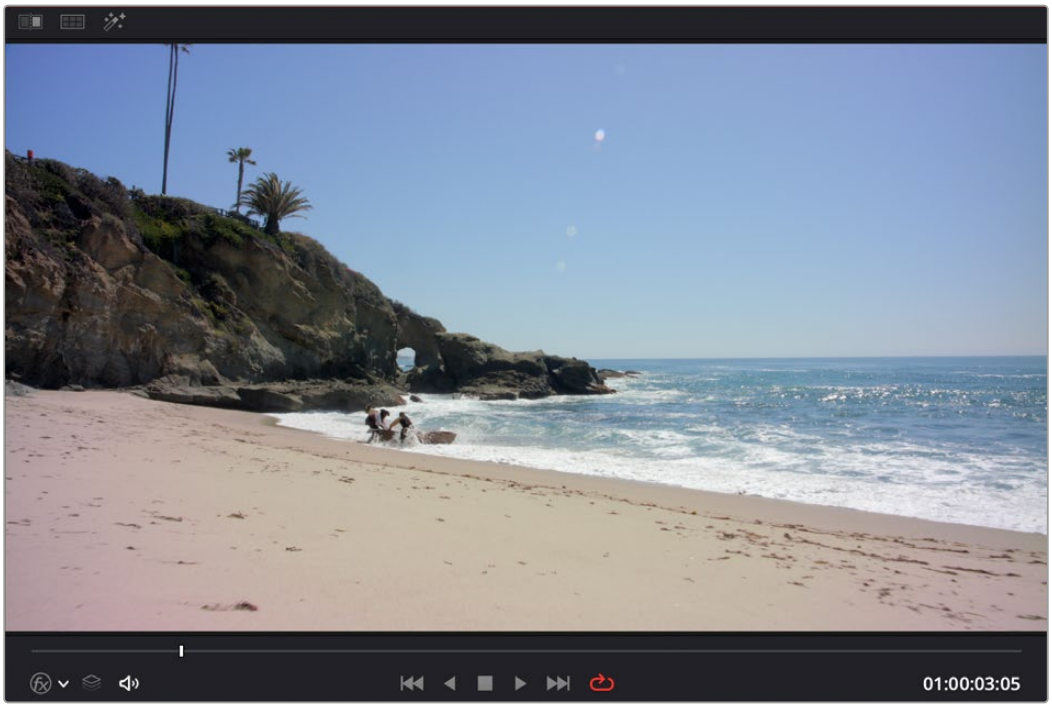
- **Transfer Direction:** This drop-down menu lets you choose which input provides the detail and which input the detail is combined with.

Details Extraction

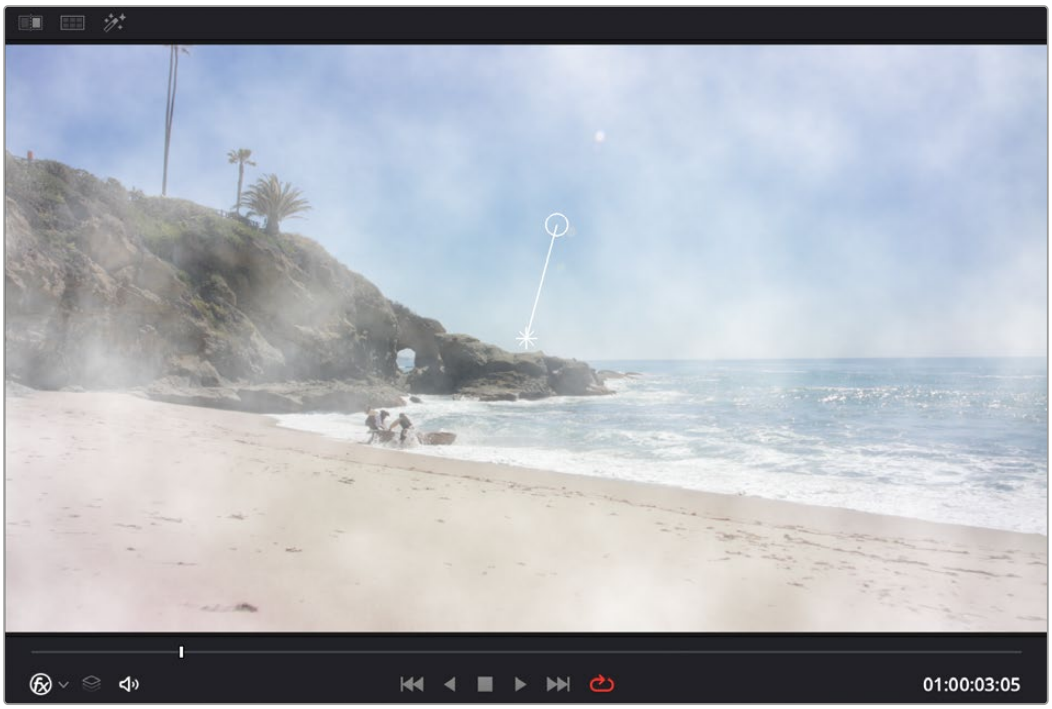
- **Frequency Cutoff:** A slider that lets you choose how much detail you want to extract for recovery. Lower values isolate finer details; higher values include progressively larger details.
- **Detail/Edge Balance:** This lets you choose between recovering all details or from the stronger edges only.
- **Strength:** This slider lets you exaggerate or attenuate the detail that's extracted for recovery.
- **Detail Mix:** At a value of 1.000, this slider blends the extracted detail with the image you're adding it to so that both layers blend together. At a value of 0.000, the extracted detail replaces whatever overlapping pixels are in the image you're adding it to. Using this slider, you can choose the best blend for your purposes.
- **Preview Detail checkbox:** Turning this checkbox on lets you see the detail that's being extracted using the Frequency Cutoff and Strength sliders.

Fast Noise

Fast Noise creates computer-generated noise patterns that can be composited on, or used to warp a video clip for a variety of special effects, such as smoke, haze, or water ripples.



Original image



The image with Fast Noise's Smoke preset applied.
The onscreen controls for position and rotation are visible.

Appearance

Controls for what noise pattern is generated. All parameters are keyframeable for changing the noise pattern over time.

- **Preset:** Select from some common noise pattern use cases: Mist, Smoke, Water Surface, River, and Heat Haze. Default is the standard noise pattern, and Custom is auto-selected if you change any of the parameters below.
- **Scale:** The size of the noise pattern.
- **H/V Ratio:** Controls the horizontal/vertical spread ratio.
- **Detail Level:** How many levels of fine detail to generate.
- **Detail Balance:** Applies weighting to the different scales of detail. The slider lets you choose between stronger large detail or stronger fine detail. A value of 0.000 removes fine detail entirely.
- **Evolution:** Changes the noise pattern gradually. This slider controls the “progress” of the noise pattern over time, rather than just modifying its current state.

Adjustment

Controls for adjusting the parameters of the noise pattern once it’s been generated. Especially useful for modifying the noise pattern’s Alpha channel for compositing. All parameters are keyframeable for changing the noise pattern over time.

- **Brightness:** Increases or decreases the gain of the noise pattern.
- **Contrast:** Moving this slider to the right makes the light areas lighter and dark areas darker in the noise pattern, increasing the contrast. Moving it to the left reduces the contrast.
- **Saturation:** This slider controls the scale between a grayscale and color noise pattern. A value of 0.000 is completely grayscale, and a value of 1.000 is fully color.
- **Color Tint:** Sets the overall color of the effect.
- **Invert Dark Regions:** Check this box to invert the dark regions to white and darken the edges in the noise pattern.
- **Invert Pattern:** Check this box to invert the color of the noise.
- **Allow Negative Values:** Check this box to apply negative values to the Output section below.

Position

Controls that adjust the center and direction of the noise pattern.

- **Position X/Y:** Location of the center of the noise pattern.
- **Rotation:** Rotates the noise pattern around its center.
- **Position Reference:** Controls how to position the effect when a clip is re-sized or moved in the Timeline.

  Sizing and FX Tracker: The noise pattern follows Sizing and FX Tracker adjustments in the Color page. For example, if you used the FX Tracker to track a camera pan, the noise pattern would move with the pan, rather than stay in one place as the shot panned underneath it.

  Keyframed Positions: The noise pattern position can be adjusted as normal using keyframes.

  The position and rotation controls can also be adjusted directly in the Viewer when the Open FX Overlay mode is selected from the drop-down menu in the bottom left of the Viewer. Dragging the star in the Viewer adjusts the X/Y position. Dragging the circle clockwise or counterclockwise sets the rotation.

Auto-Animation

These controls allow you to adjust the animation of the noise pattern.

- **Velocity X/Y:** How far to automatically advance each frame from the start position. You can keyframe these controls to change the noise pattern's direction, without adjusting its actual X/Y position. This lets you mimic motions like smoke changing direction in the wind.
- **Seethe:** Controls how far to automatically evolve each frame from the starting Evolution value.
- **Randomize Start Frame:** Aligns the skipping cycle to the current frame. This allows you to re-use a favorite effect in multiple clips without it looking exactly identical in each instance.
- **Start Frame:** Lets you set the reference frame for the skip pattern. This allows you to control the sequence of noise you get, just in case you need to match it to the same noise pattern on another clip. This frame will be repeated.

Output

These controls allow you to choose how to adjust the output of the noise pattern.

- **Preview Noise:** Checking this box shows the noise pattern alone.
- **Output:** Choose how to use the noise pattern.

  Composite Onto Clip: The noise pattern is placed on top of or mixed into the video clip.

  Composite Type: Selects composite mode for the noise pattern.

  Put Into Alpha Channel: The noise is inserted into the node's Alpha channel, allowing you to use the noise pattern for compositing purposes. Please note, you will also need to right click on the node and select "Use OFX Alpha" to activate this setting. Alternatively, you can drag the Fast Noise effect directly into the Node Graph as an FX Node instead of applying it to a corrector node, and you can use the Alpha without additional settings.

  Use to Warp Image: The noise pattern is used to distort the image.

  Input Alpha: Controls what to do with the input Alpha channel.

  - **Limits Warping Effect:** Limits the warp to certain areas as defined by the Alpha channel. For example, when you want to have a water ripple or heat shimmer on only certain part of the clip.
  - **Gets Warped as Well:** The warp affects the Alpha channel in addition to the RGB channels. For example, when warping a logo with a transparent background.

JPEG Damage

Simulates the kinds of minor or major artifacts you get when doing JPEG compression; useful for simulating compression damage.

- **Quality:** Lets you lower the bit depth of the image.
- **Resolution:** Lets you increase the size of macroblocking artifacts that appear.
- **Block Aspect Ratio:** Lets you adjust the macroblocks to be more square or rectangular.
- **Frequency Scale:** Sharpens the effect.
- **Scale Component:** Lets you base this effect on All Frequencies, the X-Frequency, or the Y-Frequency.

Texture Pop (Studio Version Only)

Texture Pop is a more sophisticated and flexible version of the Midtone Detail control found in the Primaries and HDR palette. Using the controls of this effect, you can either remove texture or exaggerate it. There are two modes of operation that determine how specific a result you can achieve.

- In Simple mode, you can apply more extreme versions of the Midtone Detail effect found in the Primaries and HDR palette. A single Details slider lets you soften or sharpen midtone detail in the image with a greater range of operation, while a Strength slider lets you exaggerate the effect further or attenuate the effect to back it off.
- In Advanced mode, you can fine-tune the softness or sharpness of high, medium, and low-frequency image detail with great specificity via seven individual “details” sliders, labeled Rough, Coarse, Medium, Small, Fine, and Tiny. This lets you adjust the textural characteristics of multiple frequencies of image detail in different ways, for example softening Fine detail while intensifying Medium detail. The Strength slider lets you exaggerate or attenuate the overall effect caused by all sliders.

In either mode, the Details/Range sliders default to 0.000, which causes no change to the image. This is the level to choose to preserve the original quality of detail in the image. They range from -1.000 (maximum softening) to +1.000 (maximum sharpening). Additionally, a set of Tonal Range controls (described later) lets you choose how much of this effect is applied to the Shadows, Midtones, and Highlights of the image, giving you even more specific control over which parts of the image are softened and/or sharpened.

Understanding Advanced Mode

Advanced mode is the most exciting way to use this effect. The best way to learn what Advanced mode does is to set all of the Details sliders to -1.000, and then raise each one individually to see what kind of image detail get reintroduced, and ultimately enhanced, if you raise each slider above 0.000. In the following image, each of the Details sliders has been set to -1, which is the maximum smoothing for each setting. The result is an image with minimal detail.

In the following example, a person and the mechanical details of a helicopter shot are smoothed by setting each detail slider to -1.000. You can see that the resulting images both retain the broad strokes of color and contrast that define each region of color, but outside of high-contrast edges, all textural detail has been smoothed to a clean gradient.

(Previous page) An image of a person with all detail smoothed,
(Above) An image of mechanical detail with all detail smoothed

Then, by raising each of the Details sliders back to 0 or even +1 one at a time, you can see exactly what kind of detail that slider is affecting. As you can see in the example of the person, the Tiny and Fine sliders are affecting only the smallest details, hairs, lines, and pores of the skin. In the helicopter detail, you can see the kind of small textures, tiny lines, and rivet details that come back.

(Top) The same image of the person with the Tiny and Fine sliders raised to add subtle detail back to the image, (Bottom) The helicopter detail with Tiny and Fine detail added back to the image

Here are two sets of generalizations that hold true if you're thinking about the detail of a human face.

- Tiny, Fine, and Small controls affect the smallest details in an image, including the pores (tiny), blemishes (fine), and wrinkles (small) of average closeup shots. Other features affected would include high-frequency edge detail of strands of hair, leaves on a tree, or text on a page of paper or screen.
- Rough, Coarse, and Medium tend to affect progressively smaller shadow contouring of faces, bodies, and objects.

Of course, the granularity of a particular type of image detail depends on how much of a closeup or long shot the clip is. When the camera is closer to the subject being adjusted, you'll be able to adjust much finer details. When the camera is distant, then even large details on the subject are affected by the Tiny, Fine, and Small controls. This means when you create an adjustment for a subject in a closeup, you'll need to make changes to the adjustment if you try and apply it to a long shot.

Mode Controls

- **Operating Mode:** Lets you choose between the Simple and Advanced modes of this plugin.
- **Color Mode:** Lets you choose between working in RGB and Luma/Chroma mode. In RGB, a single set of parameters affect all three color channels at once. In Luma/Chroma mode, two sets of controls let you fine-tune the luma and the chroma separately.
- **Output Mode:** Lets you choose between outputting the Final Result, Differences mode, which lets you see the effect differenced against the original image, and Difference Magnitude, which shows a high-contrast differencing comparison.

Details Controls

- **Strength:** Lets you exaggerate the effect of the other Details sliders further, or attenuate the effect to back it off.
- **Details:** (Simple mode only) Lets you soften or sharpen midtone detail in the image with a greater range of operation.
- **Rough/Coarse/Medium:** (Advanced mode only) These three sliders affect progressively larger contours of the image, appearing to affect the shadows and structure of the image.
- **Small/Fine/Tiny:** (Advanced mode only) These three sliders affect progressively smaller details and texture of the image, adjusting medium to tiny details, lines, and specks.

Tonal Range Controls

- **Shadows:** Lets you reduce the effect you've created in the shadows of the image, as defined by the Low Range parameter.
- **Midtones:** Lets you reduce the effect you've created in the midtones of the image, as defined by the Low and High Range parameters.
- **Highlights:** Lets you reduce the effect you've created in the highlights of the image, as defined by the High Range parameter.
- **Low Range:** Lets you define the image value that defines the transition from Shadows to Midtones.
- **High Range:** Lets you define the image value that defines the transition from Midtones to Highlights.

Chapter 165

Resolve FX Transform

The plugins in this category allow different types of animated and non-animated transforms than are possible in the Sizing palette or Clip Transform controls of the Inspector.

Match Move (Studio Version Only)

TIP: Match move workflows are now much more effectively accomplished in the Fusion page using the tools and methods found there.

The Match Move filter is a patch-based tracker that follows a pattern region defined by a tracker control. You can place as many trackers as you like by applying this filter to a node and clicking on a feature you want to track in the Viewer. Ideal features for tracking are high contrast details that have sharp angles that are clearly defined.

Each tracker control consists of (a) a center point that indicates where the tracked motion path will be centered, (b) an inner box that identifies the patch of image you're tracking (that can be resized), (c) an outer box that defines the search region for the track (that can also be resized), and (d) a patch window that shows you a zoomed in closeup of the patch you're tracking. Patch windows can be resized, and the other tracking controls hidden or shown, using controls in the Display Options section of the Match Move controls.

A tracker control in the Match Move filter

If you've accidentally placed a tracker control somewhere you don't want one, you can either drag anywhere within the inner box to move it to another location, or you can Option-click it to delete that tracker.

Once placed, you can choose how much image detail is considered for analysis by resizing that tracker control. To resize a tracker, move the pointer over the edge of the inner box, and drag to shrink or enlarge it.

This plugin will automatically derive as much motion data as the number of trackers you've placed allows:

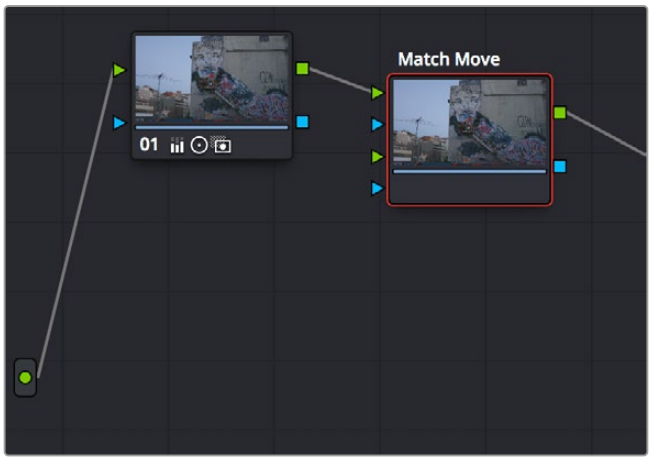
- One tracker tracks horizontal and vertical position (pan and tilt).
- Two or more trackers also track rotation.
- Four or more trackers also track perspective.
- If you place six or more trackers, then the Match Move filter is capable of automatically choosing the best tracker data from the overall collection to give you the most accurate track that's possible.

A Match Move Workflow

The following example shows the simplest complete workflow for importing a foreground clip to composite with a match move to follow a background clip that's already in the timeline. This workflow is suitable for such operations as placing a graphic as a sign on a side of a building, or into the display of a phone.

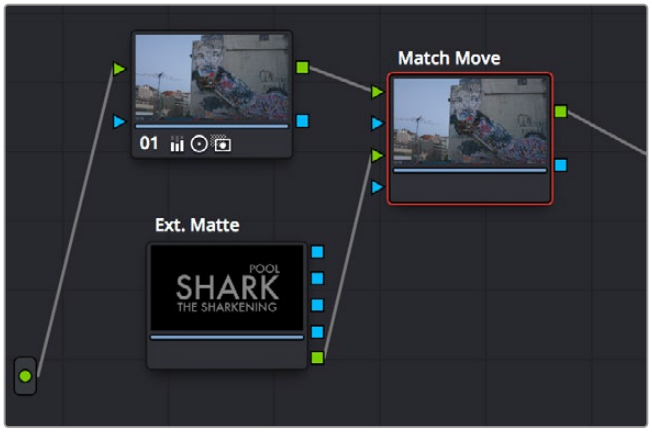
To match move:

1. Open the Media Pool in the Edit page, right-click a clip you want to match move to a clip in the Timeline, and choose “Add as Matte For Color Page Clip” to add it to the Color page Node Editor of the currently selected clip as a Timeline Matte. This is currently the only way you can match move and composite a foreground clip against a background clip in the Color page.
2. Open the Color page, make sure the background clip you want to match move to is selected, then open the OpenFX library and drag the Match Move plugin directly onto the connection from the last node in the tree to the Output, to add it as a stand-alone FX node.



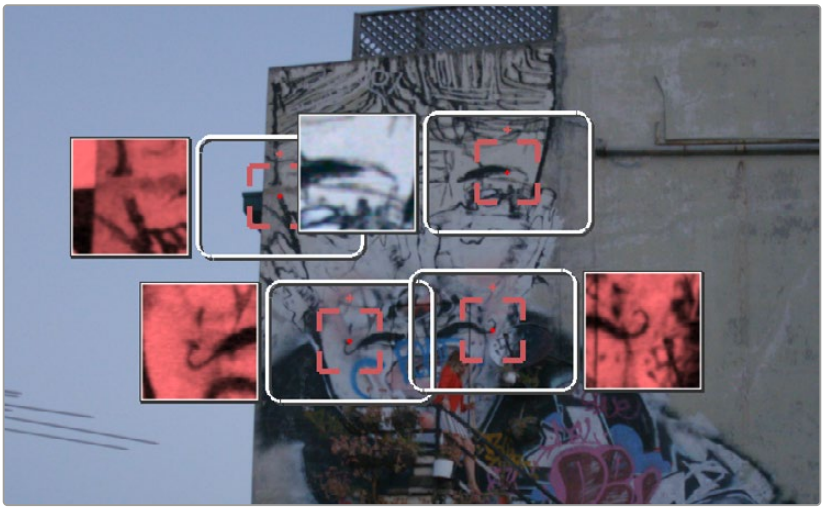
Adding the Match Move filter as a stand-alone FX node

3. Right-click any corrector node in the node tree (Node 01 in this example) and choose the clip you added in step 1 in the Add Matte > Timeline Mattes submenu of the contextual menu to expose that clip as an Ext. Matte node. Delete the connection between the new Ext. Matte node and the node it’s connected to, and then reconnect its RGB output to the second input of the FX node.



Connecting the foreground image to the second input of the FX node

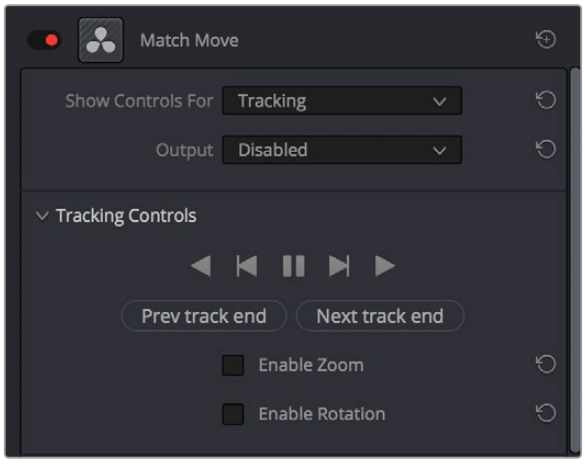
4 Select the FX node, make sure the OpenFX onscreen controls are enabled, choose whether you want to start at the first or last frames of the clip to begin the tracking process, and then click within the Viewer to place tracker controls on the surface of the image you're going to attach the foreground image to. If you want to do a perspective track, place at least four tracker patches in areas you know won't be occluded by other things in the frame. Choose features that are high contrast and angular for the best results, and try to make sure the features you track won't go offscreen or be occluded by other features within the frame. As you place tracking controls, their patch window will be tinted the color of the channel that DaVinci Resolve automatically determines will provide the best tracking result.



Adding tracker controls to the feature you need to Match Move to

5 (Optional) If necessary, you can delete trackers you don't want by Option-clicking them.

6 Now that your tracker controls are all set up, you're ready to begin the tracking analysis. If the playhead is at the beginning of the clip, click Track Forward, otherwise click Track Backward. DaVinci Resolve will automatically analyze all tracker controls within the clip until the last frame of the clip is reached.



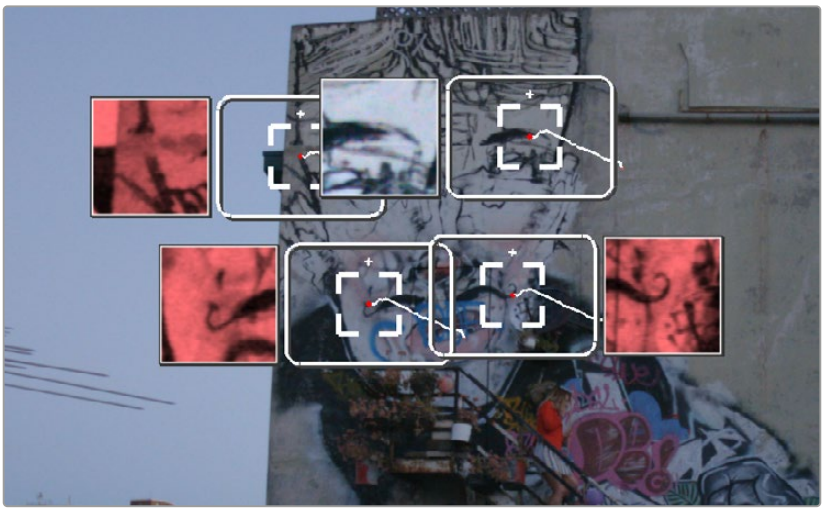
Using the Tracking controls

7 (Optional) If anything occludes a patch that's being tracked, or if the tracked feature starts going off the edge of the frame, that tracker control may veer off course and will eventually turn off. If this happens, there's a way to continue the track that's surprisingly easy:

a) Click the Track Forward or Track Backward button again to stop the analysis.

b) Move the playhead back to the last good frame of tracking data, then click the inner box of each tracker control that went wrong to make sure they're turned on (you know it's on if the patch window is displayed), and then click "Clear tracking forward" or "Clear tracking backward" as necessary to delete the incorrect tracking data. When you're done, click the inner box of each tracker that went wrong to turn it back off again, so it doesn't continue trying to track incorrectly (you know it's off if the patch window is hidden).

c) Now, place additional trackers on different features of the same surface to replace the trackers that you had to turn off.

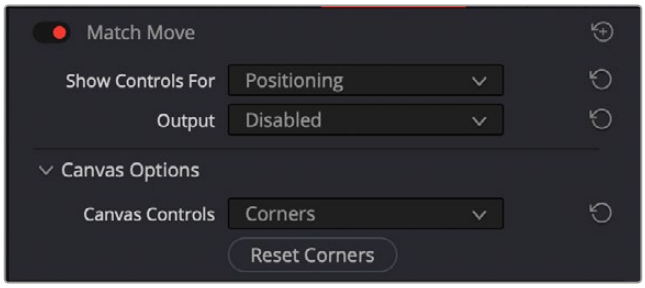


Placing more tracking controls to cover for tracking controls that turn themselves off when going offscreen or being occluded by other moving features in the image

d) Click "Track forward" again to continue the track, and DaVinci Resolve will automatically use those additional features to continue the analysis.

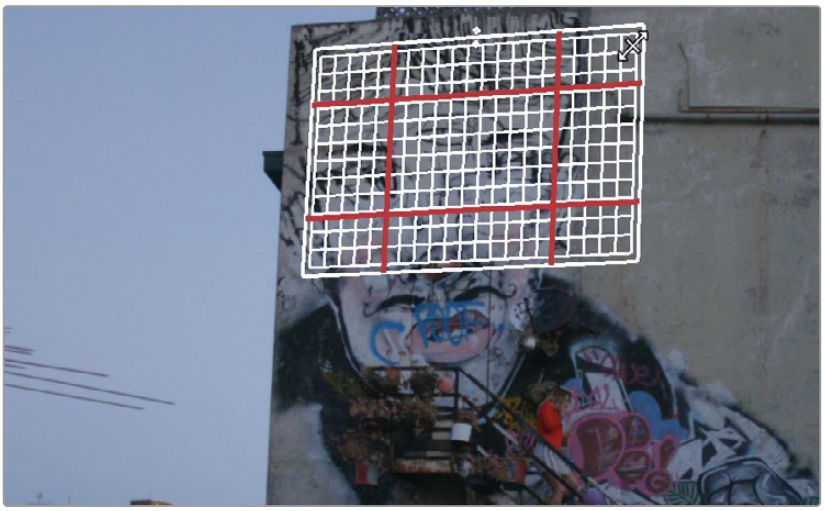
e) When the analysis is complete, turn the trackers you disabled back on again. All trackers that are turned on contribute data to the match move, for whichever ranges of frames they contain valid tracking data.

8 When DaVinci Resolve finishes its analysis, move the playhead back to the first frame of the track, and choose Positioning from the "Show controls for" pop-up menu. This takes you to the next stage in the Match Moving process.



Choosing the Positioning controls

9 A grid appears, covering the Viewer. This is the positioning canvas, and it lets you corner-pin the area in which the foreground image you connected in step 3 will be composited and tracked. You can corner-pin and resize it by dragging it by the corners, and you can move it by dragging the center.



Resizing the canvas to fit the foreground image into the background

10 Once you've positioned the grid, scrub back and forth to verify that it tracks correctly and looks right once it's in motion.

11 Choose Compositing from the "Show controls for" pop-up menu to expose the compositing controls.

12 Set the Output pop-up menu to "Composite" to output the final match-moved composite. If necessary, you can use the Composite Type and Plate Cropping controls to choose how the foreground image is blended with the background and whether you need to crop unwanted parts of the image from the edges.

The final match moved composite

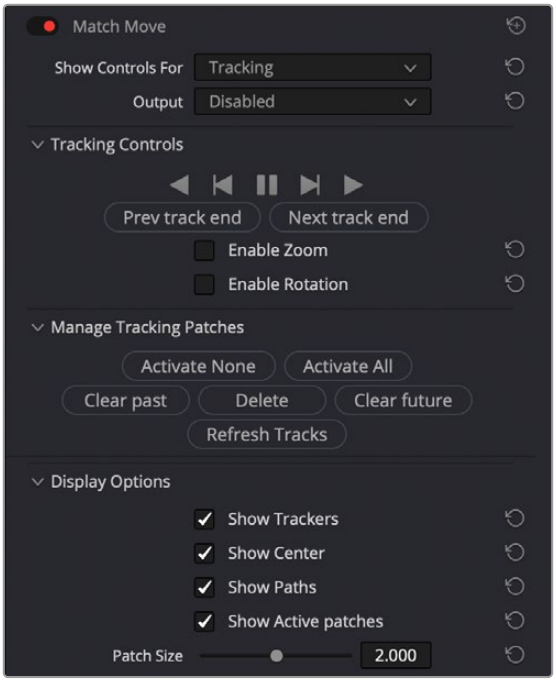
At this point, you've finished the match move.

Main Controls

The "Show controls for" pop-up menu lets you choose one of four pages of controls that take you through the match moving workflow. The Output pop-up menu lets you choose what you want to output, with choices for Disabled, Positioning Reference, and Composite.

Tracking Controls

The Tracking Controls govern the first stage of the match moving process, and this page of controls provides everything you need for setting up, executing, and refining multi-patch motion tracks.



The controls that are exposed when Main Controls is set to Tracking Controls

The Tracking Controls group

The primary controls used to initiate tracking. These consist of the tracking buttons that let you execute tracks either automatically using the outer Track Forward or Track Backward buttons, or manually using the inner Track Next or Track Previous buttons. The middle button lets you pause tracking.

The Next Track End and Previous Track End let you jump to previous and subsequent tracked sections of frames; in cases where there may be gaps in your tracking data, these controls let you jump to different segments of contiguous tracking data.

Two checkboxes let you choose whether you want to track and analyze Zoom and/or Rotation. These must be set before you begin tracking.

The Manage Tracking Patches group

The two buttons at the top let you choose which tracking patches are enabled to contribute to the overall match moving result, or disabled. Activate None and Deactivate All let you turn all patches on or off at once.

Clear Past and Clear Future let you clear bad tracking data forward or back in time from the playhead's current position, for enabled tracker controls. Delete Tracking lets you delete the tracking data at the current frame only for enabled tracker controls.

Refresh Tracks updates a tracker control's patch when the feature it's tracking changes shape, color, or lighting enough to interrupt the track. Select one or more trackers and click Place New Patch in Track to update the tracked feature at that frame.

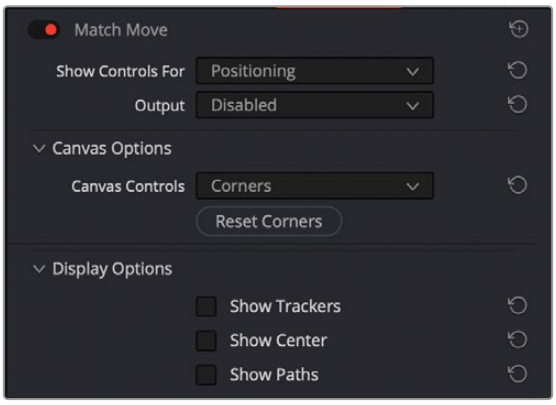
The Display Options group

This group lets you turn the visibility of different onscreen controls off and on. Checkboxes let you Show Trackers, Show Center (the red tracking center point), Show Paths (the tracked motion paths), and Show Active Patches. A slider lets you adjust the size of each patch window.

Show Comp Result lets you see the composited foreground layer against the background layer.

Positioning

The Positioning controls govern the second stage of the match moving process. They provide everything you need to transform the foreground image to fit against the background by moving, corner-pinning, and resizing.



The controls that are exposed when Main Controls is set to Positioning

Canvas Options

The Canvas Controls pop-up menu lets you switch between corner-pin controls, where dragging the four corners lets you corner-pin, dragging the center lets you reposition, and dragging the top, bottom, and sides lets you resize vertically or horizontally.

A Reset Corners button lets you reset the grid to full screen, if you need to scrap what you're doing and try again.

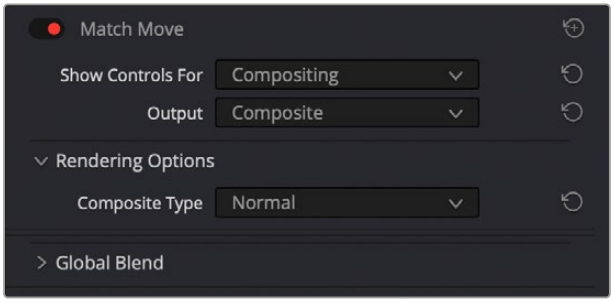
The Display Options group

This group lets you turn the visibility of different onscreen controls off and on. Checkboxes let you Show Trackers, Show Center (the red tracking center point), and Show Paths (the tracked motion paths).

Show Comp Result lets you see the composited foreground layer against the background layer.

Compositing

The Compositing controls govern the third stage of the match moving process, to use when fitting the foreground image against the background image to make a seamless composite. Note, if you need to color correct the foreground image to match the background, you'll need to add a corrector node between the Ext. Matte that's routing in the foreground image into the Color page and the FX node that's doing the compositing.



The controls that are exposed when Main Controls is set to Compositing

Rendering Options

The Composite Type pop-up menu lets you choose whether the composite that's being output is an overlay of the Ext. Matte over the background, or the background Plate only.

Plate Cropping

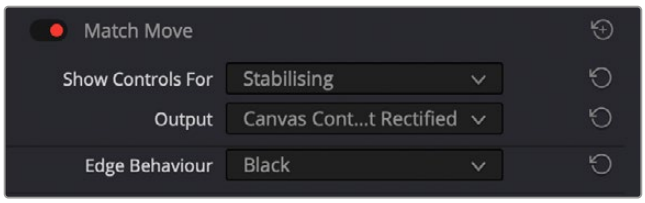
Four sliders let you crop the Left, Right, Top, and Bottom of the image, if necessary.

Global Blend

The Blend slider, present in every Resolve FX plugin in DaVinci Resolve, lets you adjust the opacity of the effect, effectively controlling the opacity of the foreground layer.

Stabilizing

The Stabilizing controls actually have nothing to do with match moving, but instead allow you to use the motion tracking accomplished with the Tracking Controls to stabilize the image. An Edge Behavior pop-up menu lets you choose how to handle blanking around the edges as a result of the background image being transformed to keep the subject of the frame in place.



The controls that are exposed when Main Controls is set to Stabilizing

Surface Tracker (Studio Version Only)

The Surface Tracker is used for applying textures and effects to flexible or deformable moving surfaces, like cloth and skin. The Surface Tracker ensures that the folding and deforming of the texture or effect is realistically matched to the folding and deforming of the surface that it is attached to in the image.

The Surface tracker is a complex effect, with many different options and controls to create the most realistic composites possible. But in all cases you simply move from left to right, using the buttons in the effect's settings.

1. Click the Bounds button, and click on the screen to define the area on the surface where you wish to apply the new texture. The bounds should select one surface at a time and not go over/on object edges.
2. Click on the Mesh button to define the control points along the natural folds and curves of the surface within the bounds.
3. Click on the Track button to analyze the motion of the surface over time, using the Mesh you just set.
4. Click on the Result button to composite the texture on top of the moving Mesh.

It is recommended that you use the Surface Tracker as a separate FX Node (dragged from the effects library directly into the node tree), rather than applied to a normal corrector node. This allows you to have access to an additional Alpha input for applying textures that have some transparency built in to them.

Across all the tabs in the Surface Tracker, the Tracked Range shows the start and end frame numbers of your clip that contain tracking data. Any existing tracking data will be reset if you modify the bounds, or mesh layout, and you will need to re-track it.

(Previous Page) The Surface Tracker in action, (Above) overlaying the logo, and warping and conforming it realistically to the folds of the shirt.

Bounds

This is where you are prompted to draw an area on the image that you want to apply the texture to. Ideally, you want to choose a frame in the clip that has the surface you want to track as close and as flat-on to the camera as possible. This frame becomes the default reference frame for the effect. Make sure that the Open FX Overlay controls are active in the Viewer to use the tool. Simply click on the image to make multiple points around the area you want to define (a minimum of three points

are required), and the effect will connect them automatically as a polygon. Boundary points should be **on** the surface for tracking, not around it. If points are accidentally placed on object edges or the background instead, it will cause errors in the tracking.

You may add multiple boundaries and multiple holes to the same image, and all boundaries will join together into one shape before subtracting the holes. The purpose of multiple boundaries and holes are to allow you to mask out complex surfaces with regions not for tracking. For example, you can make a boundary around someone's face, but use multiple holes to exclude the eyes and mouth as those change appearance quickly as the subject blinks and talks, making them exceptionally difficult to track.

Multiple boundaries are designed to work on the same surface; using multiple boundaries on different surfaces within the image will cause poor results. Separate surfaces are best tracked by using multiple instances of the Surface Tracker instead.

The boundary is not useful for rotoscoping objects, only for analyzing the motion of a surface. Rotoscoping of foreground objects can be done as described in the Tracking Using a Mask section below.

- **Click to Add Points:** These are the controls used to make boundary areas on the image.

  Boundary: The currently selected boundary area on the image. You can change the current boundary or hole by using the drop-down menu. If there are issues with the boundary (i.e., crossed edges, too few points, etc.), an error message will appear next to the boundary name.

  + Bound: Adds a boundary polygon to the image. You can have multiple boundaries defined for the same surface, and they will be joined together into one shape.

  + Hole: Adds an area to exclude tracking from the surface. Used to remove overly complex and changing parts of a surface from the effect's calculations.

  Delete: Lets you delete the boundary or hole selected in the Boundary field. Currently, this operation is not undo-able, so be careful around this button.

  Clear All: Lets you delete all boundaries and holes in the effect.

Mesh

With the boundaries now defined, you can establish the mesh over the surface to be tracked. The initial mesh serves as the starting point for tracking, so for best results the mesh should be placed when your surface is as flat-on and closest to the camera as possible.

The mesh can be manually adjusted by dragging current points (multiple points can be moved by holding command and dragging an area around the points) or clicking on an area to place new ones. Option-clicking a point will remove it from the mesh. Manually adding mesh points can be useful if there are flexible portions of the surface known to be a point where the texture should fold but which is not initially identified when placing the mesh. For example, an extended arm may not have a mesh point active at the elbow, but with a mouse click (and a basic knowledge of human anatomy), you can manually add one there. Another use case would be to add points to an area with little detail, but you know will develop detail as it rotates into view. Placing mesh points in blank areas that show little detail will not improve results and may actually degrade them, so very few points on smooth areas is desirable. A good rule of thumb is that if more than five points are created inside the boundaries, the mesh may be good enough for tracking. Points cannot be added or deleted after tracking.

A good mesh is a sign of good tracking as they go hand in hand. If your mesh has few points detected and the results don't track tightly, you can artificially improve your results. For example, make sure that the content is clearly visible. Tracking and point detection can fail if the surface is too bright (HDR), too dark, or low contrast due to working in log. To improve results, you can add a corrector node before the Surface Tracker to adjust contrast and levels manually, then run the Surface Tracker. You could

also use a corrector node with the Contrast Pop effect before the Surface Tracker to help track surfaces that are too smooth. In both cases simply disable the corrector node again after the tracking has finished.

- **Regenerate Mesh:** This button recreates the mesh at the current frame and settings and discards any manual changes that have been made.
- **Point Locations:** These controls determine which mode is used to generate the mesh points.

  Automatic: The Surface Tracker automatically locates the best details for tracking, and places mesh points on those details. In most cases Automatic will give you the best results.

  Point Number Limit: Lets you set the maximum amount of mesh points to place. The number of mesh points affects how the overlay will flex and fold, and should be set by the expected flexibility of the surface. They do not directly affect tracking speed.

  Minimum Point Spacing: Lets you set the minimum distance between mesh points. This prevents mesh points from bunching together too tightly in highly detailed areas and interfering with each other.

- **Uniform Grid:** Creates a regular grid of points in the boundary and relies on internal shape models to deform the grid during tracking. This may give better results than Automatic mode if your surface is highly detailed.

  Horizontal Spacing: Adjusts the horizontal distance between adjacent points in the uniform mesh.

  Vertical Spacing: Adjusts the vertical distance between adjacent points in the uniform mesh.

Track

This section of the effect tracks the motion of the mesh points over time. Use the Tracking Direction controls to complete the tracking procedure across the clip. After the tracking is complete, the effect does no more analysis, and any additional contrast assistance from previous nodes can be discarded after this step. For simple cases, the tracking may run completely without user intervention, but for more complex cases, a number of additional controls are used to refine the track.

Fixing a broken track will require some manual adjustments to both the mesh and the tracking data. At any time while tracking, mesh points can be adjusted either one by one, or with the lasso selection tool (Command - Drag) around the entire mesh or just parts of it. The lasso selection tool also has the ability to stretch, scale, and rotate the mesh points, making it easier to manually deform and place the mesh exactly where you want it to be, if for some reason the automatic tracking fails. However, additional mesh points cannot be added or deleted at this stage, without first resetting the tracking.

Command-Drag will allow you to lasso multiple mesh points, and scale, rotate, and stretch them, as needed.

Manually editing the mesh points at a frame only affects that frame directly; it does not affect neighboring tracking data. However, it does affect neighboring interpolated positions, which makes it good for tracking from that point onwards. For example:

- Tracking is good until frame 150 when a few points separate from the rest, disturbed by a lighting change. At frame 150 they can be manually moved back into place, then if tracking is resumed they will continue with their corrected positions.
- Tracking exists until frame 150, after which there is no data for a few frames until it resumes at 160. Editing the points at either frames 150 or 160 will cause the intermediate frames to be interpolated with these changes applied.
- Tracking exists up to frame 150 and at frame 160 onwards, frames 151-159 are interpolated. At frame 155 some points are adjusted. This creates tracking data at this frame, and now frames 151-154 interpolate from the last tracked frame to this current one, and then frames 156-159 from the current to the next tracked frame.

If an object in the frame occludes the tracked surface, for example tracking a mesh on a shirt, and the person's arm moves down through the mesh, breaking the track. You may be able to fix this issue by using an Alpha channel, as described in the Tracking Using a Mask section below.

Tracking data is also visible as keyframes in the Keyframe Editor in the FX node's Surface Tracker keyframing data, and it is also accessible as the last control at the bottom of the Track section where the data at a frame can be created or deleted directly.

- **Go to Start:** This button will snap the playhead to the first frame that has been tracked, or the frame where the boundary was created.
- **Go To End:** This button will snap the playhead to the last frame that has been tracked.
- **Tracking Direction Controls:** These controls perform the tracking analysis in the direction indicated. They are from left to right: Track Backwards, Track Backward One Frame, Pause Tracking, Track Forwards Then Reverse, Track Forwards One Frame, Track Forwards. Using these controls, you can set the track across the whole clip or limit the tracking to just a section of it.
- **Tracking Data Controls:** These controls allow you to manipulate the track data after it's been run.

  Remove Tracking Data Before This Frame: Clears all the tracking data before the current frame.

  Track From Last Known Match: This button will match the tracking data to the current frame and connect it to the last frame where tracking data exists. If there has been too much motion between those times, you can move the points approximately into place and try matching again. For example, the tracking occurs without issue until frame 150, but something moving across the scene causes an error in the track for six frames (151-157). The tracking data can be paused before it hits these frames, or these frame's tracking data can be deleted after the fact. Then at frame 158 you can press this button to continue the track from the last known good track at frame 150.

  Remove Tracking Data At This Frame: Clears the tracking data at the current frame.

  Remove Tracking Data After This Frame: Clears all the tracking data after the current frame.

- **Interaction Overlays:** These buttons control the visibility of the mesh overlays on the Viewer.

  Show: Shows the mesh at all times.

  Hide on Drag: Shows the mesh until a point is dragged, then it is hidden, allowing you to see the surface underneath for fine adjustments.

  Hide: Hides the mesh at all times.

- **Tracking Behavior:** These options allow you adjust the way the tracking operates.

  Motion Range: Controls how far to search for matches. Increase this slider if the surface is moving too quickly and the tracking fails to find it.

Mesh Rigidity: Controls how flexible the mesh is. Reduce this slider to make the mesh points more flexible. This gives you best results if the clip is noise-free and warping smoothly. Increase this slider to get a “stiffer” tracked surface with less internal warping.

Quality: The tracker can be very computationally intensive; it is recommended to use the Faster setting while making adjustments to the mesh, then use Better for the final track once all the parameters have been set correctly.

Tracking Keyframes: Controls the Surface Tracker in the standard Keyframe Editor. You can insert, delete, and navigate different keyframes from this option.

NOTE: The Surface Tracker creates data at each frame of the source clip. If the source clip is not at the same frame rate as the timeline, tracking may seem to stutter or skip frames. You can “bake” retiming into a clip by right-clicking on it on the Edit page and choosing “Render In Place” to create a result with exactly one frame for every timeline frame.

Result

Once the tracking data is complete, the Result section lets you determine what and how to composite a video layer on top of the moving surface.

- **Output:** There are six options for what to do with the resulting tracking data.

  Warp Input 2 Onto 1: Warps the Surface Tracker’s second RGB input to the shape and position of the tracked mesh and composites it onto the clip.

  Warp Input 2 Onto Blank: Warps the Surface Tracker’s second RGB input to the shape and position of the tracked mesh and passes the Alpha channel information, allowing you to perform the actual composite in another node or effect.

  Warp Input 1’s Alpha: Applies the results of the Surface Tracker to the first Key input (the second RGB and Key inputs are ignored). If the first Key input receives an Alpha channel from another node with, say, a drawn shape, or a key, or other Alpha data, it can be warped from the first frame to others.

  Create Mesh Alpha Mask: Produces an Alpha mask, which follows the position and shape of the outline of the mesh. All inputs and alphas are ignored.

  Stabilize-Warp Input 1: Performs an inverse warp to the Reference Frame (again, this should be a frame that ideally is as close to and flat-on to the camera as possible). The result is a stationary image within the boundary with all the lighting changes and details of the surface’s motion shown on it. This now stabilized image can be modified with any of DaVinci Resolve’s existing tools, bypassing any issues caused by this area’s motion in the original video clip. Once modified, you warp the result back onto the original footage by using a copy of the original Surface Tracker node but with the Rewarp Stabilized Clip setting here instead.

  Rewarp Stabilized Clip: Composites the output of the Stabilize-Warp Input 1 selection back onto the original video clip, after it’s been modified. This option is designed to be used in conjunction with a copy of a Surface node using Stabilize-Warp Input 1. It seamlessly blends whatever additional modifications that were made between the two Surface Trackers back together.

- **Overlay/Alpha Source:** Allows you to select which frames of the overlay or alpha are used to create the result.

  First Frame: Useful for freezing content from an overlay clip to use a still frame as a static texture. In DaVinci Resolve’s External Matte controls the offset can be chosen, but also you can use the same frame as the texture reference with Reference Frame.

Reference Frame: Starts at the currently defined reference frame (see below), instead of at frame 0. The reference frame is the frame which the mesh overlay is initially positioned in its “un-warped” state, and the positioning controls are active.

Each Frame: Treats the overlay or alpha as a clip, warping each frame in turn. This is necessary for animated overlays or re-warping stabilized content. It should be noted that in the Key controls on the Color page, when an External Matte is selected, options appear to control the lifetime of the external clip.

- **Expand/Contract:** Allows you to add or remove pixels from the edges of the overlay or alpha. It is important to note that the expanded area is not tracked and will not be stabilized to the content.
- **Softness:** Blurs the edge of the Expand/Contract tool to blend more realistically into the scene.
- **Motion Blur:** This slider lets you add motion blur to the overlay to preserve the illusion that it was actually captured with the scene.
- **Overlay Placement:** These controls let you set the initial transform options for the image you want to overlay on the mesh.

  Go To Reference: Moves the playhead to the selected reference frame.

  Set to Current: Sets the current frame under the playhead as the reference frame.

  Reference Frame: Shows the frame number at which the overlay is originally positioned and un-warped (the point from which the warp to every other frame is calculated). The positioning controls appear on screen when the clip is at the reference frame. A frame where the surface’s view is largest and least warped is the best starting point for rendering onto other frames.

  Positioning: Lets you choose how to adjust the overlay position.

  - **Sliders:** Choosing this option exposes a set of transform sliders (X/Y position, zoom, rotate, etc.) that let you manipulate the overlay’s initial position.
  - **Interactive Canvas:** Choosing this option exposes draggable frame controls in the Viewer, allowing you to transform the overlay using mouse controls. The Viewers shows a large grid with 9 regions; you can drag in any of them to move, skew, or warp the overlay.
  - **Interactive Pins:** Adjusting the image in this mode is done by manually placing control points, called pins, in the Timeline Viewer. Adding one pin only gives you position control. At least two points are required for scaling and rotation. Dragging on one of the pins scales or rotates the image around the other pin. Using three pins, you can create perspective distortions by dragging any one of the pins. You can add up to four pins for unique corner pinning distortions.

  Reset Position: Resets the on-screen overlay back to its default state.

- **Interaction Overlays:** These buttons control the visibility of the mesh overlays on the Viewer.

  Show: Shows the mesh at all times.

  Hide on Drag: Shows the mesh until a point is dragged, then it is hidden, allowing you to see the surface underneath for fine adjustments.

  Hide: Hides the mesh at all times.

- **Compositing:** Lets you set the composite blend mode for the overlay operation. For more detailed information on each blend mode, *see Chapter 50, “Compositing and Transforms in the Timeline.”*

  Composite Type: A drop-down menu of all the possible composite operations.

  Opacity: This slider controls the transparency of the overlay.

Using the Surface Tracker

The Surface Tracker is a deep and versatile tool that can be used to realistically isolate a moving surface for a variety of effects. The examples below can get you started on discovering its uses.

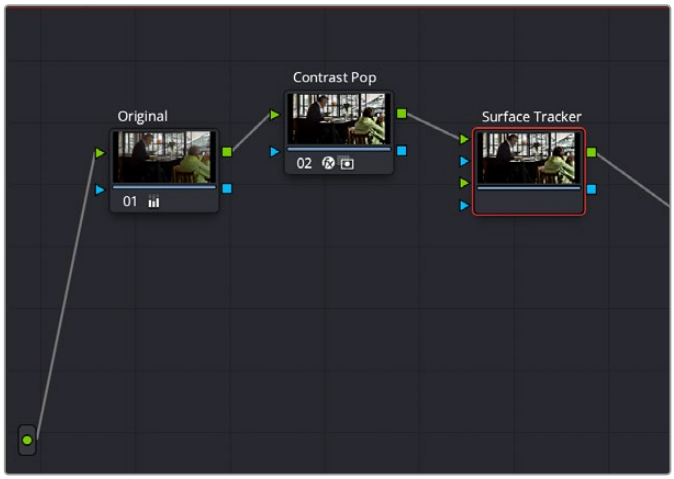
Using the Surface Tracker to Composite a Logo onto a Fabric Surface

One of the more common use cases of the Surface Tracker is to overlay a still graphic on top of a moving surface and have the graphic behave realistically as the surface deforms and warps. In this example, we will add a simple logo to the back of a jacket.

The first step is to define the boundary of where we want the surface analyzed. For best results, you need to place the boundary on the surface to be tracked, not around it, and try to find a frame where the surface is flat on to the camera and as large in the frame as possible.

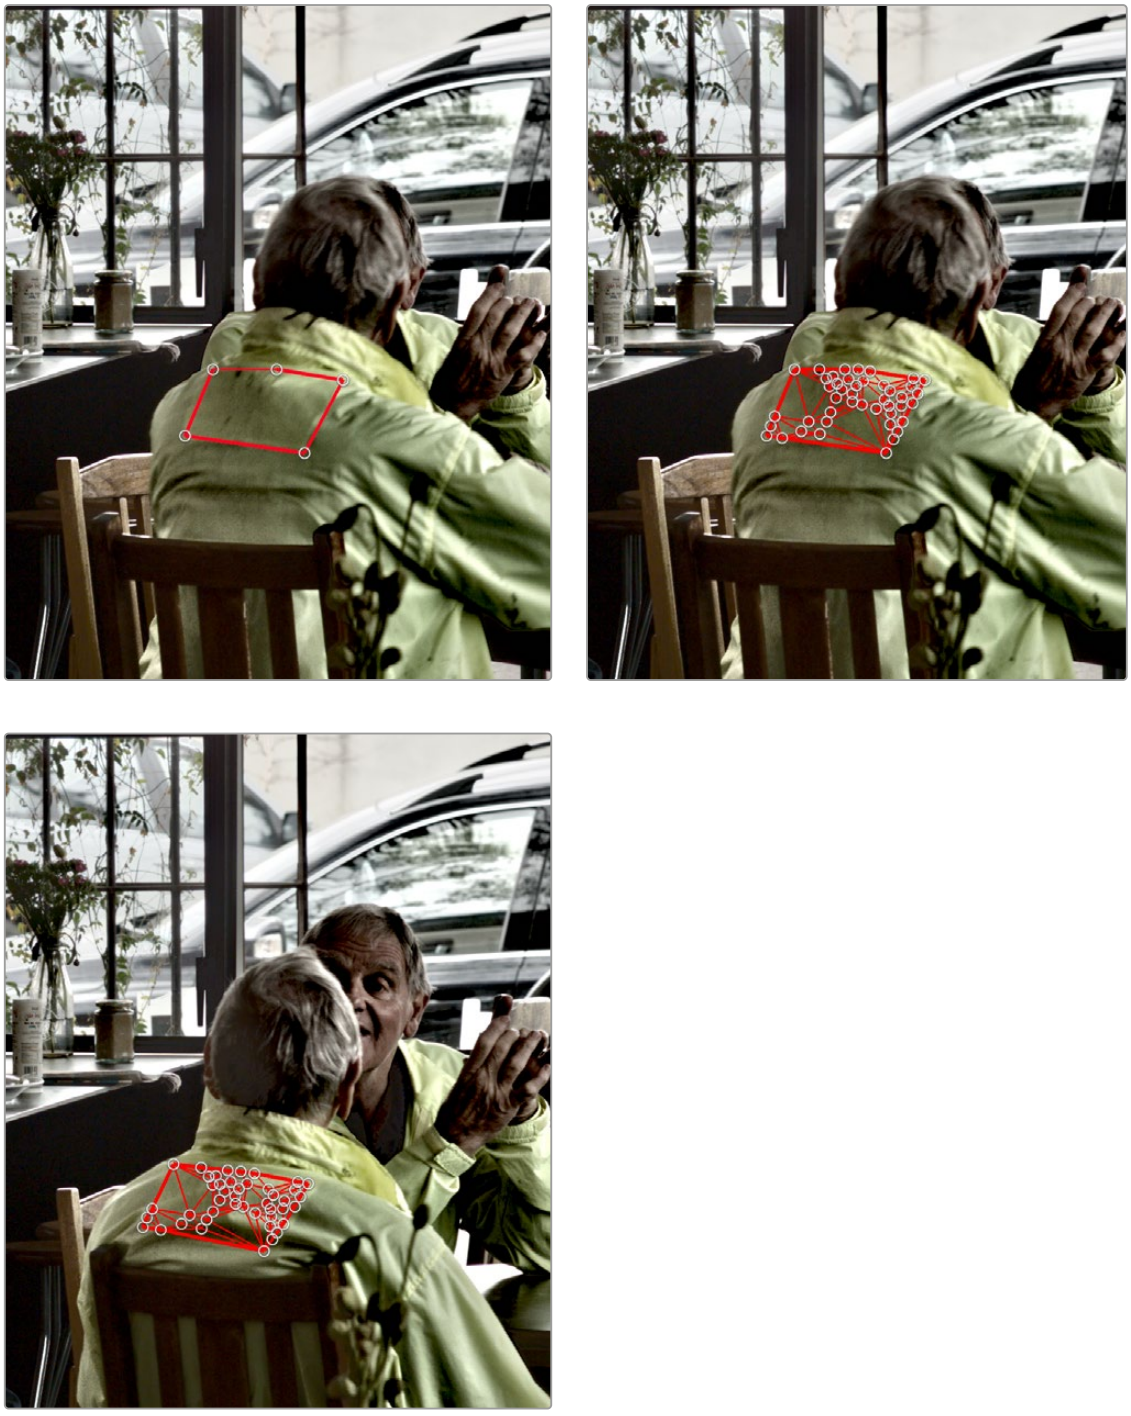
The next step is to define the Mesh within the surface to be warped. In this case, we will leave the Point Locations setting at Automatic to have the effect apply the mesh points. Ideally, there will be more than five mesh points for a good track. Unfortunately, this surface doesn't have enough detail to make a good mesh, so we will temporarily add a Contrast Pop node before the Surface Tracker in order to artificially enhance its details.

Creating the initial boundary to isolate the surface of the jacket where the logo will be applied



By adding the Contrast Pop FX before the Surface Tracker input, we can artificially increase the detail inside the boundary, giving it a better surface to form the mesh.

COLOR

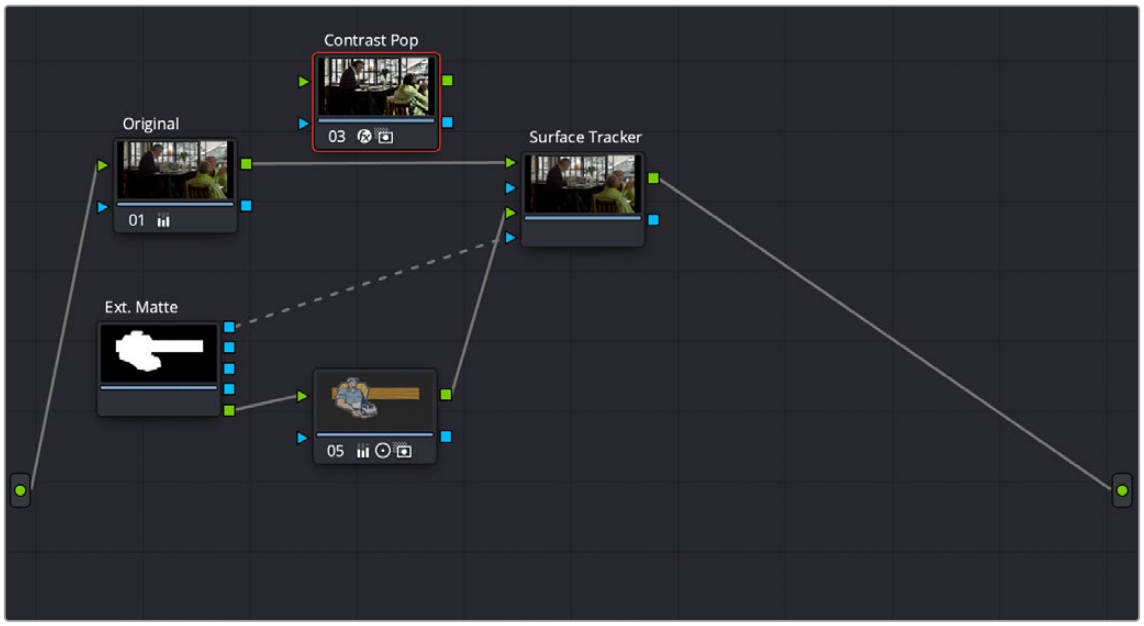


The Tracker analyzes the Mesh movement throughout the rest of the video clip.

Next, we will track the Mesh's motion using the Track Forward button and leave the rest of the controls at their defaults. Note that the track continues to warp and fold correctly, even when the subject leans back in his chair.

With the surface now correctly analyzed, we no longer need the Contrast Pop node, so we can disconnect it at this point. Next, we will drag the logo (a .png file with transparency) from the Media Pool, over into the node tree, where it comes in as a matte. We then add a corrector node after the matte, so we can adjust the color/saturation/brightness, etc. of the logo. Next, we set the RGB and Key

connections of the nodes through the matte and corrector nodes, and into the second RGB and Key inputs of the Surface Tracker. This is shown on the node tree below:

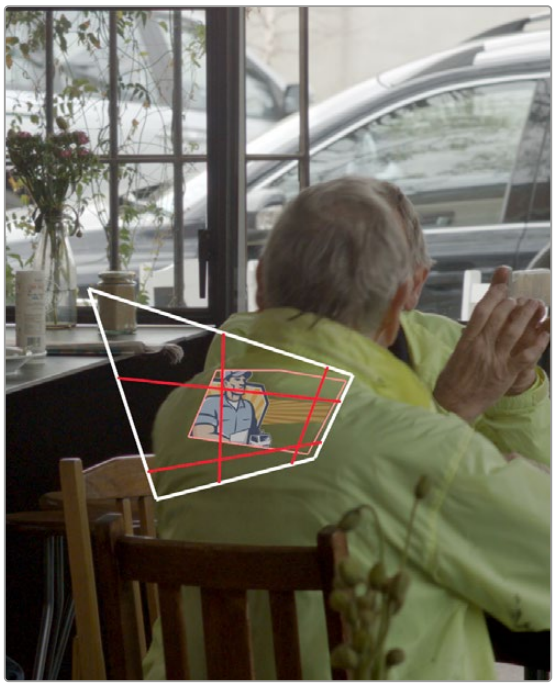


The node tree, showing the layout of the RGB and Key inputs to composite the logo over the jacket

Now, moving to the Result section, we set the following parameter:

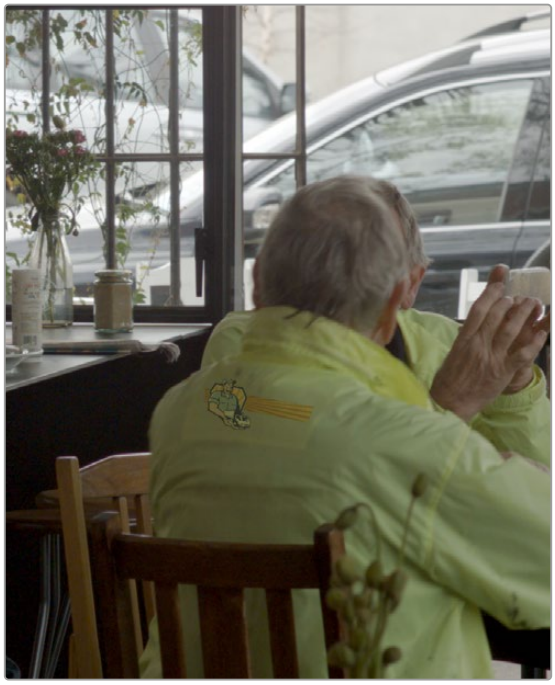
Output: Warp Input 2 onto 1 - This will take the second RGB and Key input (logo) and deform it over the original image coming in to RGB input 1.

Then we will click on the Go To Reference button to take the clip to its reference frame, and in Positioning, use the Interactive - Canvas tool to reframe the logo to look like it's on the same plane as the jacket.

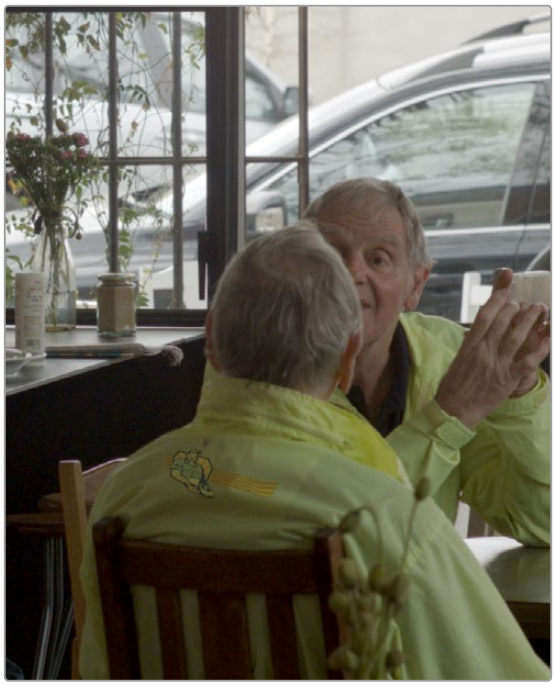


Adjusting the logo in the Interactive Canvas mode to transform it to make it appear it's in the same plane as the jacket

For the last step, we change the Composite Type from Normal to Overlay to make the logo blend in better to the surface of the jacket. Notice how the logo is deformed by the mesh to wrap around the curves and folds of the jacket, and it tracks along with the man as he leans back in his chair.

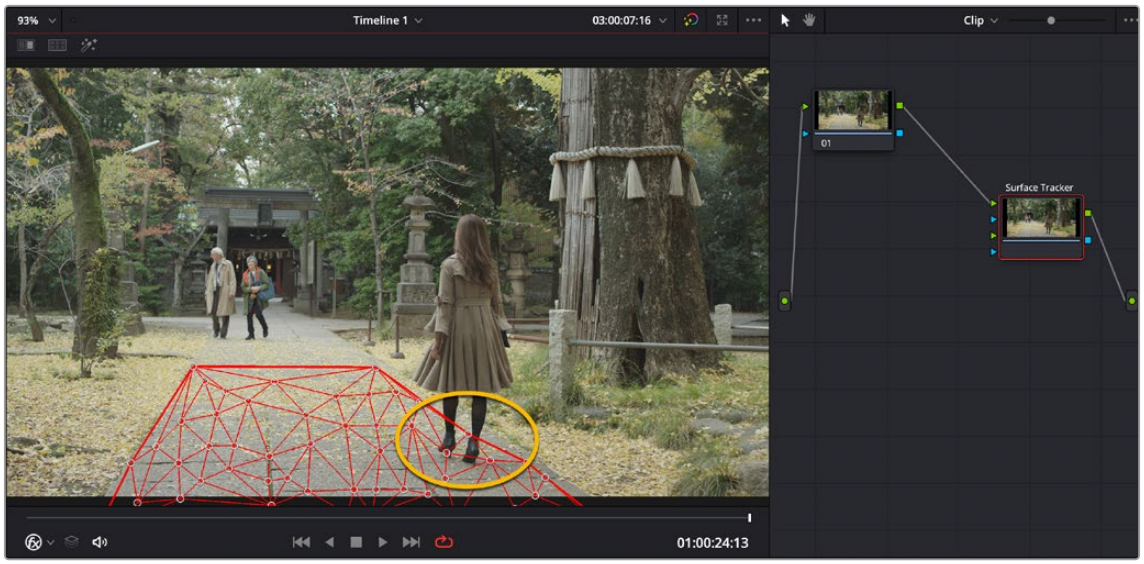


The finished Surface Tracker composite; the logo now adheres to the curves and folds of the jacket and tracks along with the man as he shifts positions in his chair.

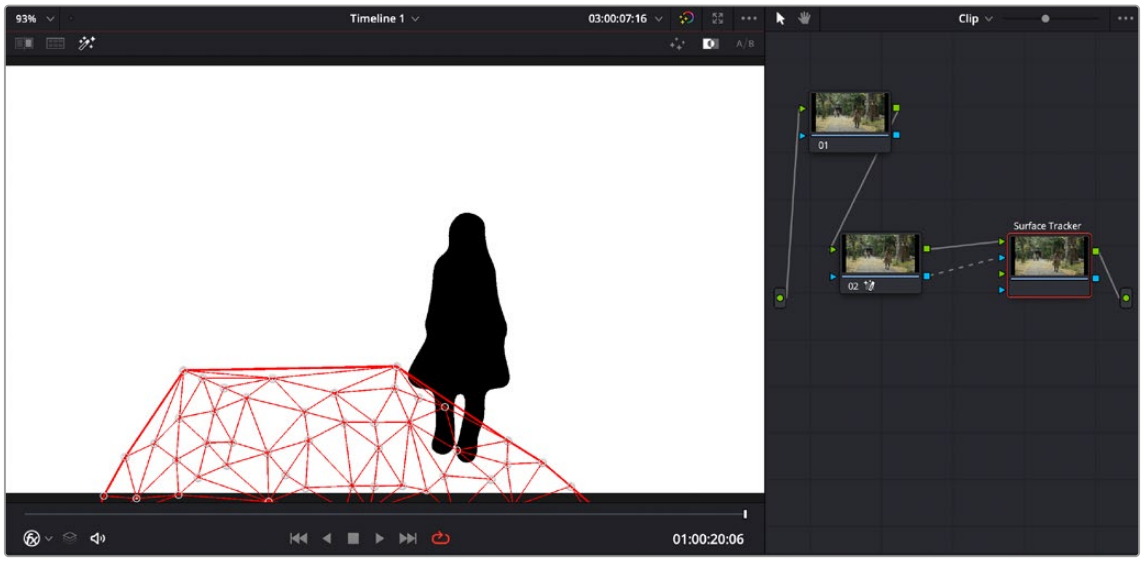


Tracking Using a Mask in the Surface Tracker

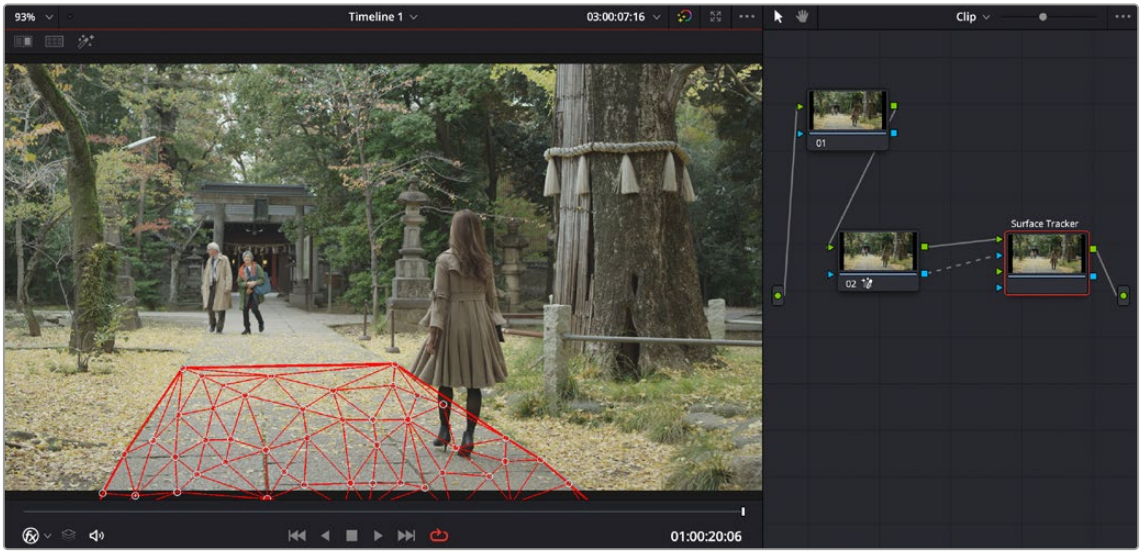
If there is an object occluding the surface to be tracked, then an input key can be used as a tracking mask to exclude the blocking object from the track. Areas of full alpha (completely white) in the Alpha channel are analyzed for tracking, while other areas are excluded. Any appropriate effect, window, or qualifier can be used as the Alpha channel generator. For example, in the shot below, the path has the surface mesh applied to it, however the woman walking over the path breaks the mesh tracking. By connecting a node's key output with a Magic Mask applied to it that picks out the shape of the walking woman, then inverting that mask (so the woman is black, while her surroundings are white), the mesh ignores her legs and feet as they pass through it and only tracks points in the white areas (everything other than the woman).



A problem trying to track the path's surface; as the woman walks through the mesh, the points attach themselves to her feet instead of the path, breaking the tracking on the right side of the path.



By connecting an inverted key from a Magic Mask node of just the woman, the tracking ignores the woman walking through the mesh (anything black), and only tracks points in the white part of the Alpha channel.



The resulting mesh is now properly attached to the path's right side and tracks correctly as she walks through it.

In the final step of the Surface Tracker, the overlay with alpha is composited over the original clip with alpha, so if using a tracking mask, it is recommended to disconnect it from the Surface Tracker's key input after the tracking is complete.

Using the Surface Tracker's Stabilize Warp

The Surface Tracker's Stabilize Warp operation allows you to use the mesh to freeze a section of video in place to make it easier to use with certain other operations. This is useful when the surface you are modifying is difficult to isolate with other tools due to its movement. Using the Surface Tracker to stabilize areas is a bit different to set up.

- Initially you want to set the Surface Tracker's mesh tracking on a surface you want to work on, as explained earlier in this chapter.
- Once complete, in the Result section you use the Output mode called Stabilize-Warp Input 1, and then feed that RGB output to a new corrector or FX node.
- This will isolate just the mesh surface and freeze it in place, allowing you to make any adjustments needed. This method is different than, say, a window qualifier, which sticks to the video and moves with it. In Stabilize Warp, the "window" (actually the mesh defined boundary) is frozen in place instead, and the video moves and warps within it.
- Once your adjustments are finished, you then feed the RGB output of the corrector node back into an exact copy of the first Surface Tracker node. The copied Surface Tracker node's Output then needs to be set to Rewarp Stabilized Clip instead. This re-lays the adjusted mesh back on to the original video clip. Directly copying an FX node like the Surface Tracker is not currently supported. To copy the Surface Tracker, you must grab a still into your Gallery, then right-click on it and append the still's node graph back into your same clip, deleting the excess duplicate nodes other than the Surface Tracker.

For example, in the clip below we will use the Surface Tracker to remove a small mole from the woman's chin. Normally, we could use a Patch Replacer FX to put a smooth area of skin nearby over the mole. This shot is tricky to use effectively in the Patch Replacer because the subject cocks her head while she's talking, as the camera trucks around her.

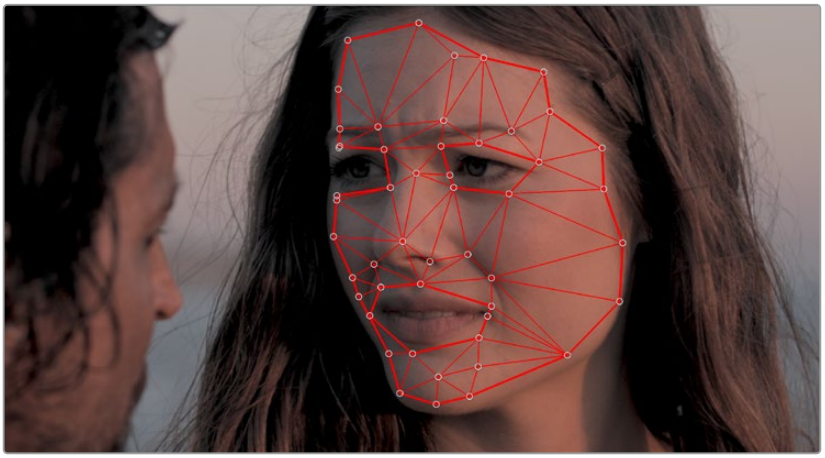
This movement on all axes means that the area of skin underneath the source patch is changing angle and lighting all the time, ruining the effect. While the patch replacer does

support tracking, the mole is on her chin and her talking also causes the skin around her cheek to deform, making it unsuitable for a simple track.

In this case, we can use the Surface Tracker's Stabilize Warp function to "hold" those face area pixels in place under the source and target patches, patch them, and then make a Rewarp Stabilized Clip version of the Surface Tracker to lay those corrected pixels back onto the original image.

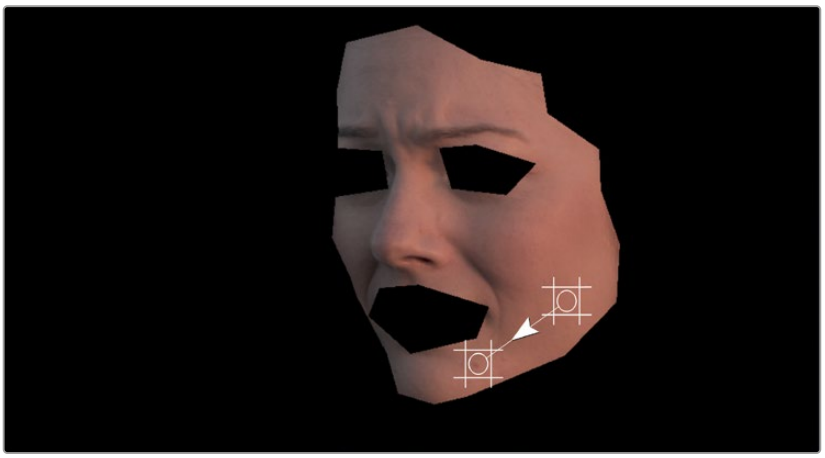
We want to remove this mole from the woman's chin. Because of camera movement, combined with her chin and cheek deforming as she talks, this is difficult to achieve with the Patch Replacer alone.

First we will create a mesh on her face and track it as described above. Making holes for the eyes and mouth so their rapid movement does not disturb the mesh on her face.



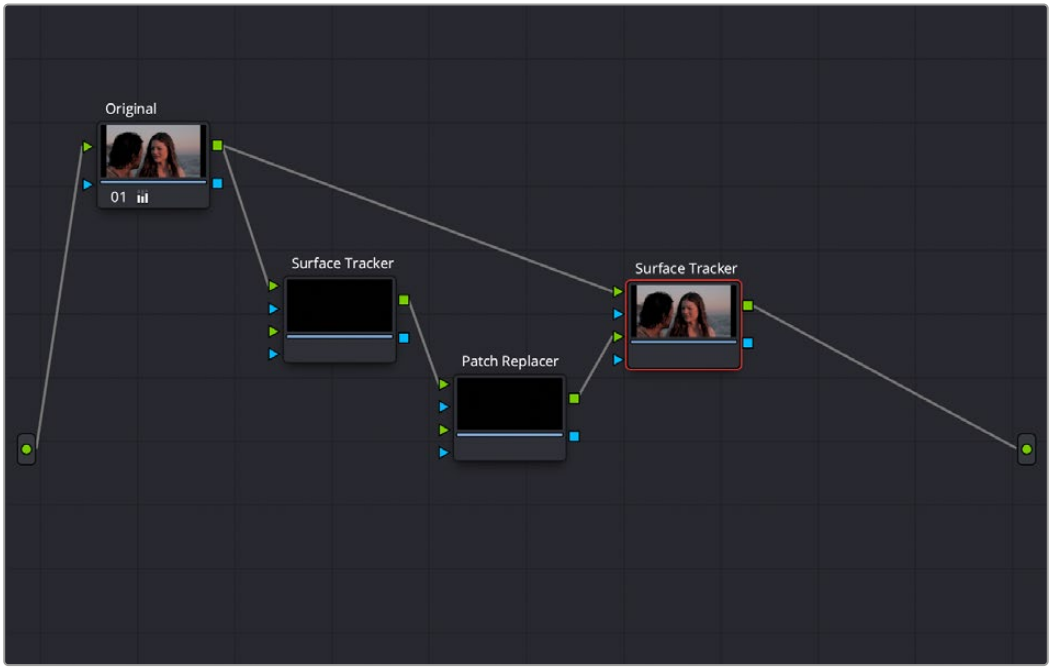
We apply the mesh to her face and track it, leaving holes in the mesh for her eyes and mouth.

Once the tracking is complete, in Result we will choose the Output mode Stabilize-Warp Input 1. This will freeze the mesh in place and give us the resulting output, which we will feed into a Patch Replacer node. Now we can simply use the Patch replacer statically to hide the mole using another area of skin. No tracking is required. Because the mesh is static, and the video warps within it, this area now perfectly matches the angles, lighting changes, and skin stretching of the area as she talks.



The frozen mesh stays in place (the face) and the video warps inside it. This allows us to use a static Patch Replacer to replace the mole area, with a smooth area on her cheek. No additional tracking is required.

At this point, we will then make an exact copy the Surface Tracker node, and place it after the Patch Replacer. To copy the Surface Tracker node, we must grab a still of the current clip, and then right-click on the still in the Gallery and select Append Node Graph to duplicate it back into our node tree. We want to delete any excess nodes added, and keep only the copy of the Surface Tracker. Then in the copied Surface Tracker, we need to select “Rewarp Stabilized Clip” from the Result tab’s Output mode. Then connect the original clip to RGB input 1, and the output from the Patch Replacer to RGB input 2, as shown in the node graph below:



The node tree showing the correct setup for Warp Stabilizing the mesh. The first Surface Tracker node has its Result Output set to “Stabilize-Warp Input 1.” The second copy of the Surface Tracker node has its Result Output set to “Rewarp Stabilized Clip.” The actual mole removal will take place in the Patch Replacer FX node.

Our finished effect now shows that the mole has been replaced, and regardless of her jaw movement or the camera position, the source patch always matches perfectly to the lighting and position changes over time. This makes for a much more seamless and convincing effect.

The resulting shot perfectly hides the mole (above), no matter her facial position or camera movement.

Transform

The Transform Resolve FX adds considerable control over the standard transforms in the Inspector's Sizing or the Color page Sizing palette. This effect includes all the standard Position, Tilt, Zoom, and Rotate controls but adds corner pinning, two kinds of on-screen controls, motion blur, and Edge behavior controls.

General

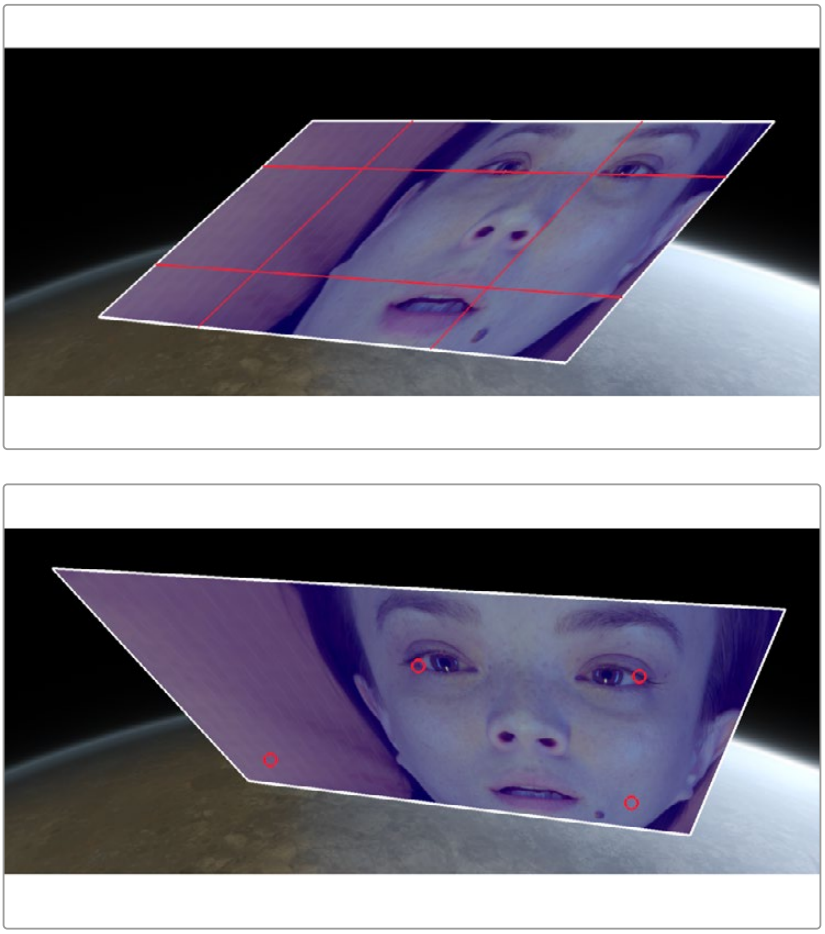
- **Control Mode:** This drop-down menu includes three methods for controlling the transforms. One is based on sliders in the Inspector, while the other two are based on manipulating the Viewer's image.

  Sliders: Uses sliders and checkboxes in the Inspector to control the transforms. This method has no Viewer overlays with which to control the position, scale, or rotation but provides exact control using numeric values.

  Interactive-Canvas: Choosing this mode moves the controls from the Inspector to the Timeline Viewer. The Viewer's controls are shown as a bold white outline and four vertices, one at each corner. You can drag on any part of the white outline for stretching, squeezing, and corning pinning. Dragging the center of the image repositions the frame. The red subdivision overlays make it easy to create shearing effects by dragging line segments to move two corners simultaneously.

Interactive-Pins: Adjusting the image in this mode is done by manually placing control points, called pins, in the Timeline Viewer. Adding one pin only gives you position control. At least two points are required for scaling and rotation. Dragging on one of the pins scales or rotates the image around the other pin. Using three pins, you can create perspective distortions by dragging any one of the pins. You can add up to four pins for unique corner pinning distortions.

TIP: You can Option-Click on a pin to remove it or use the Reset Canvas button to remove all the pins.



Resolve FX Transform Interactive-Canvas mode (Top) and Interactive-Pins mode (Bottom)

Only one Control mode can be active at a time. For instance, you cannot make adjustments with the sliders and then switch to one of the interactive methods. The sliders will be reset once a different method is selected. However, can you apply two Transform effects to a clip, adjusting one with Sliders and the other using an interactive method.

Position Controls

- **Canvas Keyframe:** Only displayed when the Control mode is set to Interactive-Canvas or Interactive-Pins. The Canvas Keyframe has no control except for a keyframe button allowing you to keyframe the changes you make in the Viewer.
- **Reset Canvas:** Resets any interactive changes made in the Viewer and any keyframes created from those changes.

The following parameters are only displayed when the Control Mode is set to Sliders.

- **Position X and Y:** Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.
- **Zoom:** Allows you to blow the image up or shrink it down.
- **Rotate:** Rotates the image around the center.
- **Width:** Stretches or squeezes the image in one direction only.
- **Height:** Stretches or squeezes the image in one direction only.
- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and bring the right of the image forward. Higher values stretch the image more extremely.
- **Flip Horizontal/Vertical:** Two checkboxes let you flip the image in different dimensions.

  Flip Horizontal: Reverses the image along the X-axis, left to right.

  Flip Vertical: Reverses the clip along the Y-axis, turning it upside down.

Image Adjustment

- **Crop:** This checkbox exposes the crop tools, allowing you to selectively remove parts of the frame from each side.
- **Edge Softness:** This control sets the amount of feathering to the Alpha channel for compositing.
- **Edge Rounding:** This control rounds the corners of the Alpha channel for compositing.

Animation

- **Motion Blur:** Keyframing the transform so the frame moves rapidly will create a blurring effect. The amount of the blur is controlled using the Motion Blur slider.

Advanced Options

- **Edge Behavior:** This menu determines how edges of the frame are handled when the transforms are scaled smaller than the Timeline Resolution.

  Transparent: The area outside the transformed image is set to be transparent, allowing the video on tracks underneath this one to be shown behind the image.

  Reflect: The image is flipped and flopped to create a mirrored image, which extends to the Timeline Resolution frame boundary.

  Wrap-Around: Duplicates the image to create a video wall effect, which is used to fill in the space to the Timeline Resolution frame boundary.

  Replicate: Duplicates the outermost pixels along the edge of the image. The pixels are stretched out from each side to reach the Timeline Resolution boundary.
- **Composite Type:** Sets the Composite type for blending multiple video layers together.

For more information on what each Composite type does, *see Chapter 50, "Compositing and Transforms in the Timeline."*

Global Blend

- **Blend:** Lets you dissolve between the image with no Transform applied and one with the Transform fully applied.

Video Collage

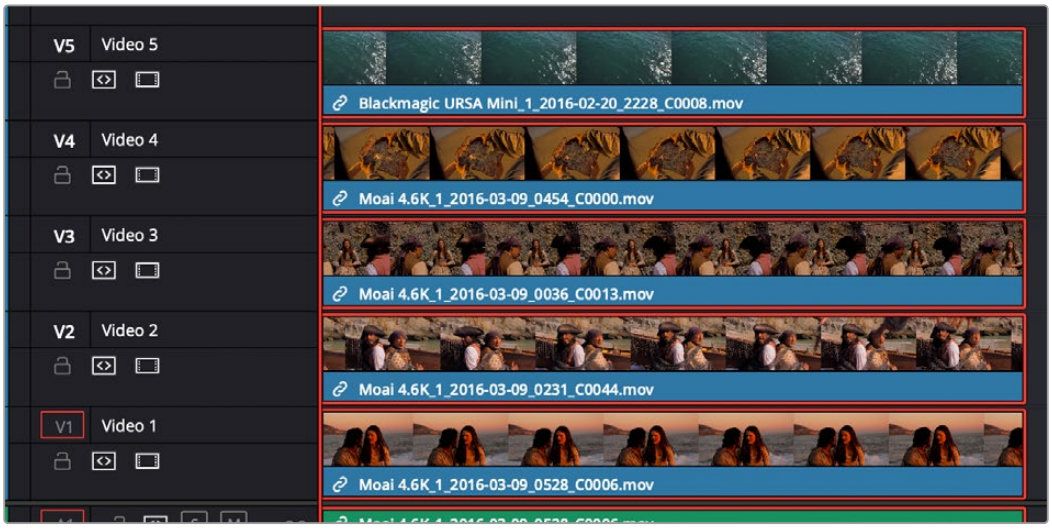
Video Collage is designed to make it easier to create grid-based layouts of multiple video layers to create different kinds of split-screen effects, where each video layer appears within a “tile” that can be styled in different ways. Layout controls let you choose how many rows and columns there are, which determine how many tiles are available to arrange tiles of video next to one another in different ways, with additional controls for creating offsets, changing the margins around and spacing between the tiles, and rounding the corners of each tile.

This effect is designed to be used in the Cut and Edit pages, and there are two ways that you can set this up, which are chosen using the Workflow drop-down menu.

Create Background

The Create Background option is perhaps the simplest way to create a split-screen using this effect. This mode creates a frame with holes in it, behind which you can position multiple layers of video. These clips are placed on tracks underneath the background clip in the Timeline, and use each clip’s individual sizing controls in the Inspector (which can be used via on-screen Transform controls in the Viewer) to scale and position them correctly within the holes. The Video Collage effect is applied to the topmost superimposed video or still image clip in the Timeline, in order to use that clip as a background for the frame.

In the following example, the Video Collage effect is applied to the clip on track 5, which has four other clips underneath it in a stack, each of which has been positioned to fit in one of the holes of the frame.



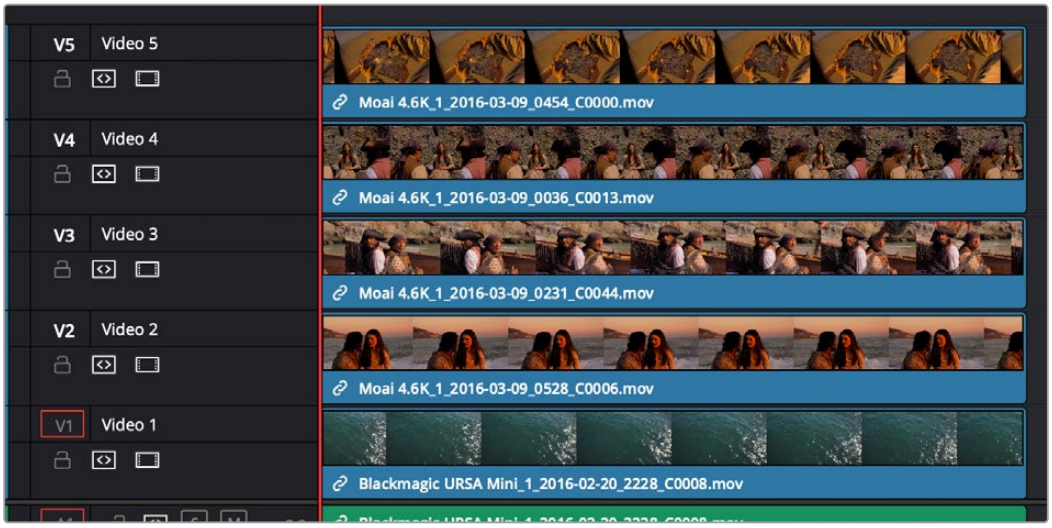
A stack of clips to create a split-screen effect; the top-most clip is used as the background by the Video Collage effect in Create Background mode, while the stack of clips underneath are all positioned to fit into the holes created in the top clip.

Create Background mode makes it easy to create a split-screen layout of different clips without having to resize them with precision to align the edges and sizes of each clip. The width of the frame that's created gives some wiggle-room to reposition and animate each individual clip within the hole it shows through. You can see the resulting effect created in the previous example below.

The resulting split-screen effect, with four clips arranged to show through the holes created in the top "background" clip that's creating the frame; you can see the onscreen controls corresponding to the clip on track 4 that have been used to position and resize it to fit.

Create Tile

This mode of operation is a bit more work to set up, as it requires you to create a layout in one instance of this effect, but it gives you more options, automatically transforming each layer of video in your stack of clips in the Timeline to fit a layout you design. The best way to work in Create Tile mode is to edit a stack of superimposed clips in the Timeline, but this time if there's a clip you want to use as the background, it should go at the bottom of the stack.



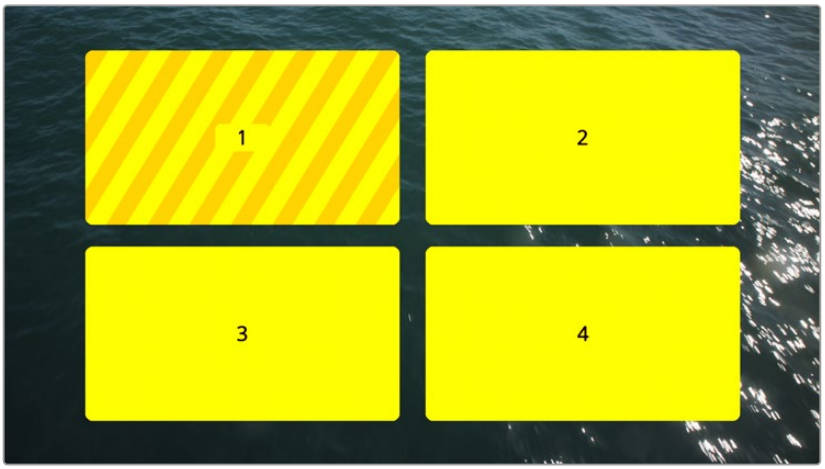
A stack of clips to create a split-screen effect in Tile mode; the bottom clip is going to be used as the background.

Then, apply the Video Collage clip to the topmost clip, and set the Workflow drop-down menu to Create Tile. Immediately, you'll see that the current layer has been fit inside the first rounded tile of the default layout of four tiles. For clarity, video tracks 4, 3, and 2 have been muted so you can see the current clip turned into a tile against the bottom clip that serves as the background for this arrangement.

The topmost clip set to create the first tile in a layout; video tracks 4, 3, and 2 are disabled to show the top clip against the bottom clip that's being used as the background.

Ultimately, you'll use Paste Attributes to apply a copy of this effect to each clip on the Timeline that's supposed to fit inside a tile, and once you choose which clip goes inside each tile, that's what will create the arrangement. Before you do that, however, you need to customize the layout.

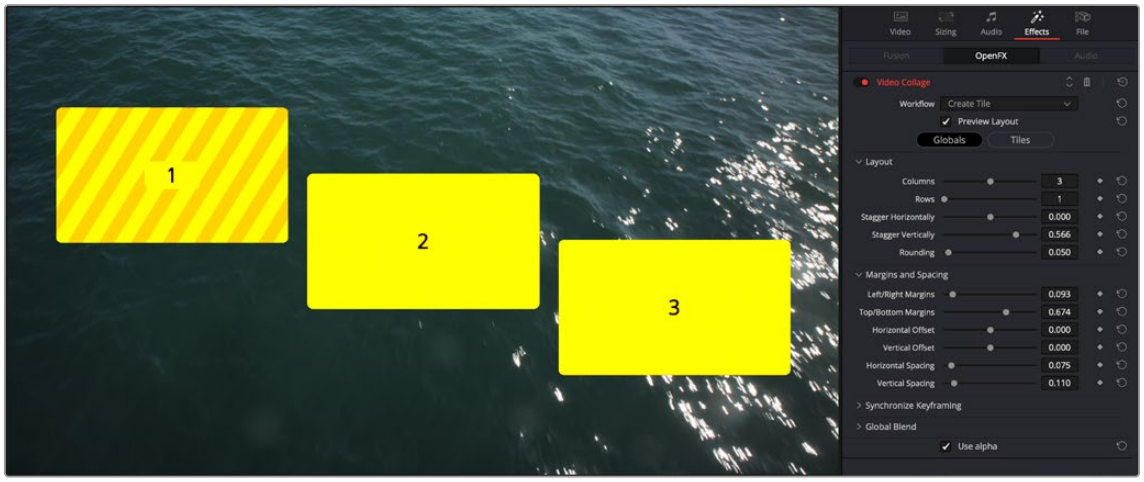
To get a preview of the entire layout for further customization, turn on the Preview Layout checkbox in the Inspector. This draws a preview of how all the tiles will be placed using the current layout. Using this preview, you can make whatever changes you want to set things up, before you copy this plugin to all the other clips in the stack.



Turning on Preview Layout to customize the layout

With Preview Layout enabled, you can use the Layout controls below to choose how many columns and rows of tiles there are, to stagger the tiles horizontally or vertically, to round or square off each tile

by a variable amount, and to alter the margins and spacing. In this way, you can create a wide variety of different symmetrical layouts really easily. In this example, we'll create a layout with one row, three columns, that's staggered vertically.



Our new customized layout, shown next to the Inspector controls for this effect

Now that this is done, we'll turn off Preview Layout to focus on the current clip's integration into our layout, and we can see that it doesn't quite fit into the box. Click the Tiles button in the Inspector. This reveals the Tile-specific controls, which include the Resize Content controls. Click the disclosure control to open these up, and use the Pan, Tilt, and Zoom controls to make this image fit into the tile full screen.

Tiles controls in the Inspector with Preview Layout disabled, so we can focus on customizing the current tile

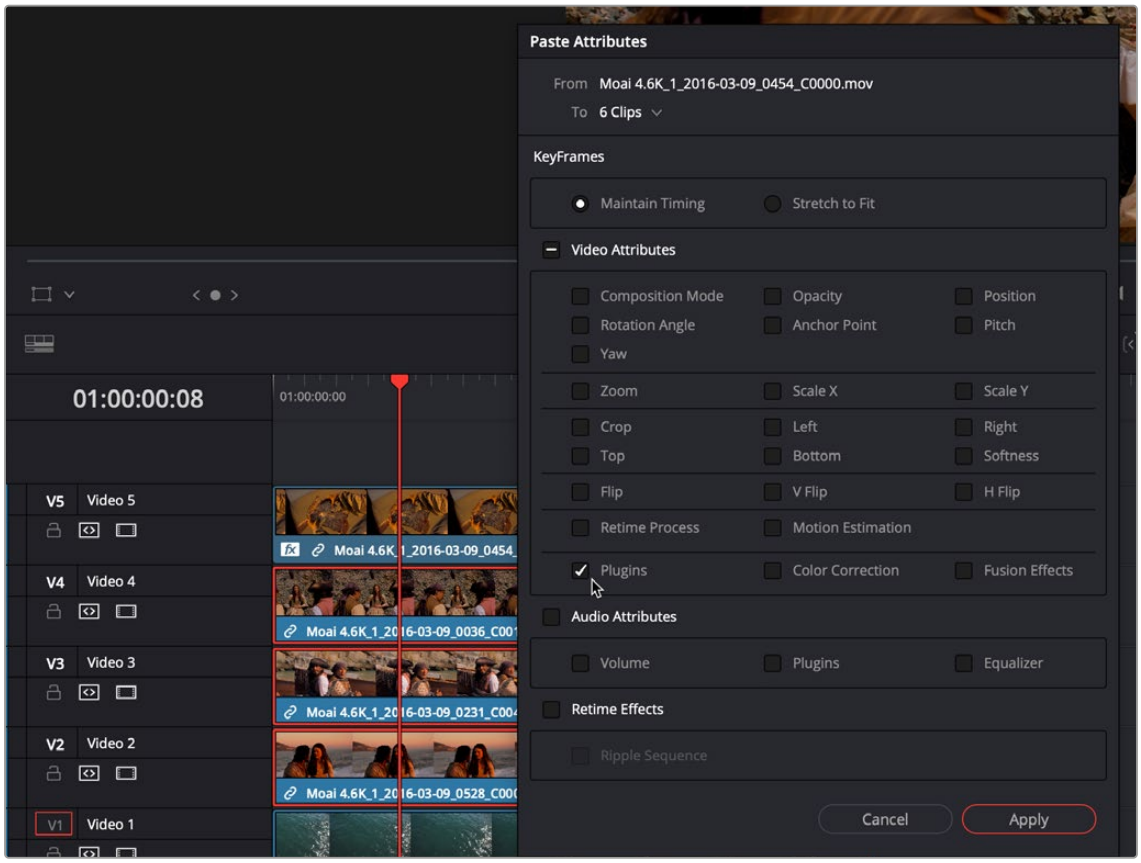
You should also note the Active Tile drop-down menu. This menu serves two purposes. First, it defines which tile the current clip is displayed within. This becomes important later on when you apply this effect to multiple superimposed clips. However, it also determines which tile you further customize using the Tile-based controls of the Inspector. If needed, tiles can be individually styled.

The Manual Tile Management checkbox is off by default, which enables DaVinci Resolve to automatically update the number of tile entries in the Active Tile drop-down menu with items equal to the number of grid positions (or grid nodes) defined by the rows and columns you've set, without you needing to do anything. For simple symmetrical layouts, this is easiest. However, if you turn Manual

Tile Management on, you gain the ability to add and delete tile positions manually, which enables other options. For now, we'll leave this turned off.

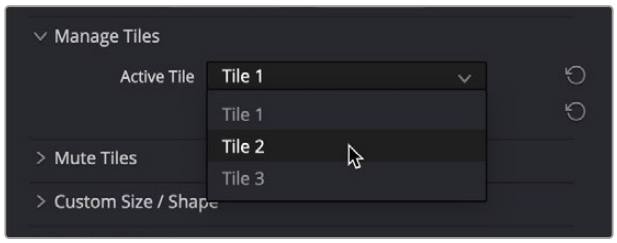
(Left) The Active Tile drop-down with Manual Tile Management turned off, (Right) The Active Tile controls with Manual Tile Management turned on, and additional controls for manual tile management displayed

So, now we've created a custom overall layout, and we've tailored the top clip in the stack to fit the first tile in the layout. Now it's time to apply this effect to the next two clips in the stack (remember the bottom clip will be used as a background, so it doesn't need this plugin applied to it). Select the top clip with the effect applied to it in the Timeline, and press Command-C to copy it. Then, select the next two clips, right-click one of them, and choose Paste Attributes (Option-V). When the Paste Attributes window appears, turn on the Plugins checkbox, in Video Attributes and click Apply. Those two clips disappear as they receive the Video Montage effect and fit themselves into Tile 1, just like the top clip.



Using Paste Attributes to apply the copied effect from the top clip to the other clips in this arrangement

To assign each clip to the correct tile in the layout, select each clip in the arrangement, one at a time, open the Effects panel of the Inspector, click the Tiles button in the Inspector (if necessary), and set each clip to be the next available tile in the Active Tile drop-down menu. In this example, the top clip was in Tile 1, the second clip down will be in Tile 2, and the third clip down will be in Tile 3.



Assigning the Active Tile for each layer in the Timeline

TIP: If you enable the Open FX Overlay of the Timeline Viewer, each tile has an overlay that lets you click a tile in the Viewer to make that the Active Tile.

If you like, you can rearrange which clips go into which tiles using this control, but for now we'll keep things simple. As you do this, each tile becomes populated, and the final layout is revealed, with the background clip showing behind everything. If necessary, you can use the Resize Content controls (in Tiles mode) to resize each tile's contents to fit the tile better.

The current layout, with each clip in the stack assigned to a different tile

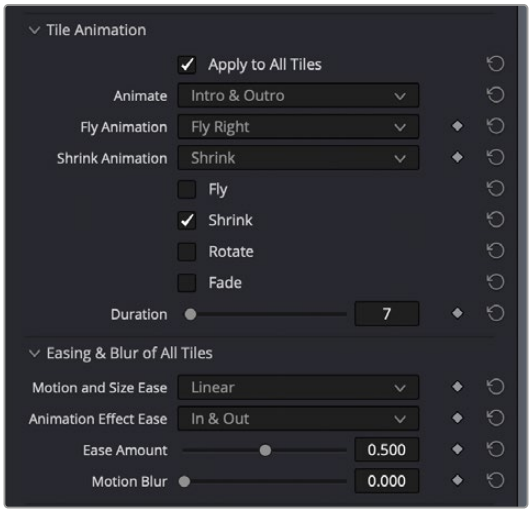
NOTE: If you've customized a layout, copied and pasted attributes to the other clips you want to use in that layout, and have assigned each clip to its position in the layout, and you then decide you need to make a change to the Globals layout controls, you'll need to go through the process of copying the updated effect, pasting attributes to the other clips, and reassigning each clip to the appropriate position in the layout to make that update to the other clips as well.

So, these are the overall workflows of the Video Collage effect. There is, of course, much more you can do, but this is the basis of how you create your initial layout.

Animating Tiles and Advanced Layouts

One of the more powerful aspects of the Video Collage effect is the ability to quickly and easily create animated intros and outros for each tile. These effects can be fully automated over a customizable duration, or their duration can be manually keyframed. All animations can be automatically eased, and you can also enable motion blur for the Fly, Shrink, and Rotate animations.

When you use these controls in Create Background mode, the transparent holes through which other clips in the background show through are animated to “open or close” to reveal the contents. When used in Create Tile mode, the actual tile and its contents are animated to fly, shrink, rotate, and/or fade to appear or disappear.



Tile Animation controls let you create automatic Intro and/or Outro animations.

Additionally, you have the ability to keyframe the Mute, Start and End Column and Row parameters, Tile Styling and Drop Shadow parameters, and other aspects of tiles in Tiles mode, either individually or all together.

In particular, the Start and End Column and Row parameters let you create tiles that span multiple grid positions, and also move tiles from one grid position to another. Without keyframing, this lets you create more kinds of layouts with asymmetric arrangements of large and small tiles. With keyframing, you gain the ability to easily create sophisticated grid-based animations to move tiles from position to position, and to have tiles expand and contract to encompass neighboring tiles in the layout, all with a minimum of keyframing.

Tile Animation controls let you create automatic Intro and/or Outro animations.

Keep in mind that, when using multiple instances of the Video Collage effect on superimposed clips in the Timeline, once you've defined your overall layout and used Paste Attributes to copy a particular instance of this effect with your layout to the rest of the clips, you need only keyframe each instance of each tile within the clip it's applied to. Furthermore, since Intro and Outro animations are applied to the entire duration of the clip, you can easily offset each Intro and Outro animation by offsetting the clips in the Timeline.

TIP: If you change the duration of clips in a stack that are creating a Video Collage effect, you can use the Synchronize Keyframing controls in Globals mode to offset all keyframes applied to that instance of the Video Collage effect by the same amount. You could do the same thing by opening the keyframe track or Curve Editor for all Video Collage parameters in the Timeline and offsetting them that way, but this provides a quick shortcut.

Video Collage Controls

Here's a detailed explanation of all the parameters found in the Video Collage effect.

- **Workflow:** Defines what the output of Video Collage is, depending on how you want to use it.

  Create Background: Outputs a frame with holes, behind which you can position individual layers of video to show through.

  Create Tile: Outputs a single tile, transformed and styled to be one element of a multi-tile layout
- **Preview Layout:** Turning on Preview Layout lets you see a graphical preview of the entire layout, and how each tile fits together. In Create Tile mode, this lets you configure how you want the layout to look before you copy the clip and use paste attributes to apply this effect to the rest of the video layers you want to arrange into a split-screen.
- **Globals/Tile buttons:** Choose between the Globals controls, which expose controls that let you adjust the overall layout, and the Tiles controls, which let you choose the currently active tile and style it.

Layout

These controls appear in Globals mode.

- **Columns:** Choose how many vertical columns worth of tiles there are.
- **Rows:** Choose how many horizontal rows worth of tiles there are.
- **Stagger Horizontally:** Lets you create an offset from one row to the next in a balanced way, so the rows are all staggered from one another.
- **Stagger Vertically:** Lets you create an offset from one column to the next in a balanced way, so the columns are all staggered from one another.
- **Rounding:** Rounds the edges of each tile in the layout. A value of 0.000 sets the edges to be square. Increasing rounding increasingly curves the corners of each tile, until a value of 1 sets the tile to be perfectly round.

Margins and Spacing

These controls appear in Globals mode.

- **Left/Right Margins:** Alters the spacing from the edge of the frame to the left and right edges of the group of all tiles. Increasing this parameter makes all tiles progressively more narrow, as they squeeze in towards the center of the frame.

- **Top/Bottom Margins:** Alters the spacing from the edge of the frame to the top and bottom edges of the group of all tiles. Increasing this parameter makes all tiles progressively shorter, as they squeeze in towards the center of the frame.
- **Horizontal and Vertical Offset:** These two sliders let you offset the group of all tiles from the center however you like.
- **Horizontal and Vertical Spacing:** These two sliders increase or decrease the spacing between each tile, making them narrower or wider as a result.

Synchronize Keyframing

These controls appear in Globals mode. They're basically a built-in utility that lets you offset all Globals and Tiles parameter keyframes that are applied to the current effect, to account for times when you've done elaborate keyframing to create animated split-screen effects, and you then need to change the duration of the clip this effect is applied to. Instead of forcing you to expose the keyframes of each parameter in the Timeline in order to move them, these controls let you move all keyframes for all parameters forward or backward by a particular number of frames, all at once.

- **Offset Frames:** Lets you specify how many frames you want to offset all keyframes applied to this effect forward. Negative values move keyframes to the left.
- **Apply Keyframing Offset:** Executes the offset.

Manage Tiles

These controls appear in Tiles mode.

- **Active Tile:** This menu serves two purposes. First, it defines which tile the current clip is displayed within. This becomes important later on when you apply this effect to other superimposed clips you want to use together in a layout. However, this control also determines which tile you further customize using the Tile-based controls of the Inspector. If you enable the Open FX Overlay of the Timeline Viewer, each tile has its own overlay that lets you click a tile in the Viewer to make that the Active Tile.
- **Bring Tile Forward/Send Tile Back:** These two buttons let you rearrange the order of tiles in the Active Tile drop-down menu.
- **Manual Tile Management:** While this checkbox is turned off (the default), changing the Columns and Rows parameters automatically updates the Active Tile drop-down menu with one tile per node on the resulting grid arrangement. Turning this checkbox on lets you Add and Delete tiles manually, which lets you create more advanced layouts with overlapping tiles and asymmetric spacing between tiles.

Mute Tiles

These controls appear in Tiles mode. A single checkbox parameter, Mute Tile, lets you enable and disable the visibility of the active tile. This checkbox is keyframable, so you can animate the appearance and disappearance of different tiles to create different effects.

Custom Size/Shape

These controls appear in Tiles mode. They let you further customize layouts on a tile-by-tile basis and can also be used to quickly and easily animate a single tile to move and resize itself around the grid of the overall layout.

- **Start/End Column and Row:** These four controls serve two purposes, letting you change a tile's position by row and column number, or enlarge a tile to encompass multiple tile row or column

positions (“spanning”). To use these parameters, you must first choose which tile you want to adjust from the Active Tile drop-down menu. With the tile you want to edit active, you can then drag the appropriate sliders to create either effect, as explained below.

To change Tile Position: When adjusted together so that the Start and End values are identical, they let you manually adjust the position of each tile in the grid that’s defined by the number of rows and columns you’ve set. This is particularly useful when you want to quickly keyframe animated changes to tile position, in order to jump a tile around the grid of the layout.

To make a tile span multiple positions: Setting the Start and End Row and/or Column parameters to different values changes the currently active tile to span multiple grid positions in the layout, making that tile bigger in order to create asymmetric arrangements of larger and smaller tiles. You can also keyframe these values to easily animate the effect of a tile expanding to occupy more grid positions, or shrinking from occupying several grid positions to occupying a single position.

Choose how many rows/columns and in which directions you want that tile to span. Note that if you span multiple rows or columns that have been offset, the resulting tile is enlarged to encompass the entire rectangular region defined by the outer boundaries of both offset tiles.

- **Custom Size/Shape:** Turning this checkbox on enables the rest of the controls in this group, enabling you to set individual scale and rounding for the active tile that’s selected.
- **Custom Scale:** Lets you adjust the size of the active tile independently of the other tiles.
- **Custom Rounding:** Lets you adjust the rounding of the active tile independently of the other tiles.

Resize Content

These controls appear in Tiles mode. They let you resize the image being fit within each tile to show exactly what you want shown.

- **Pan/Tilt/Zoom:** These three sliders let you move and resize the video layer shown inside of the active tile to fit however you need it to.
- **Edge Behavior:** These settings allow you to control how the edges of the video layer respond inside the tile.

  Transparent: Any positioning that goes past the edge of the video is transparent, showing the Tile Color set in the Tile Styling options.

  Reflect: Any positioning that goes past the edge of the video mirrors back on itself.

  Wrap: Any positioning that goes past the edge of the video repeats itself.

  Replicate: Any positioning that goes past the edge of the video shows a duplicate of the edge stretched to the boundary of the control, essentially filling in the remaining space with the pixels used at the extreme edges of the video clip.

- **Move With Tile:** Defines how the image is fit into the tile when the tile size changes due to other parameters of the Video Collage effect.

  Position Only: The video content in the tile only is sized using Pan and Tilt; Zoom is ignored.

  Position and Scale: The video content in the tile is sized using Pan, Tilt, and Zoom.

Tile Styling

These controls appear in Tiles mode. They let you add a colored border and adjust the opacity of all tiles or just the currently active tile. These parameters are animatable.

- **Apply to All Tiles:** When checked, this applies any changes made in the Tile Styling parameters to all tiles in the Video Collage, regardless of which tile is currently active.
- **Tile Border:** This slider controls the width of the tile's border. It has a possible range of values from -0.250 to 0.250, where negative numbers expand the size of the border inside the tile, and positive numbers expand it outside the tile.
- **Tile Color:** Allows you to chose the background and border color of the tile.
- **Tile Opacity:** This slider changes the transparency of the tile itself; it does not effect the video clip inside the tile. The possible ranges are 0.000 (fully transparent) to 1.000 (fully opaque).

Drop Shadow

These controls appear in Tiles mode. They let you add and customize a drop shadow, either to all tiles or just to the currently active tile. These parameters are animatable.

- **Apply to All Tiles:** When checked, this applies any changes made in the Drop Shadow parameters to all tiles in the Video Collage, regardless of which tile is currently active.
- **Strength:** This slider controls drop shadow transparency. The possible ranges are 0.000 (fully transparent) to 1.000 (fully opaque).
- **Color:** Allows you to choose the color of the Drop Shadow.
- **Drop Angle:** Lets you set the angle that the shadow is cast from. The slider represents 360 degrees of movement from -180.0 to 180.0.
- **Drop Distance:** Allows you to set the distance that the shadow appears from its source tile. The possible values are from 0.000 to 0.200.
- **Expand:** This slider controls how far the shadow expands from its origin. The possible values are from 0.900 to 1.250.
- **Blur:** Allows you to control the amount of diffusion of the Drop Shadow. The possible ranges are 0.000 (no blur) to 1.000.

Tile Animation

These controls appear in Tiles mode. They make it easy to create simple intro/outro animations to bring all or some tiles onscreen, and to push all or some tiles offscreen, in different ways. The Animate drop-down menu determines whether this animation will be automatic or manually created using keyframes.

- **Apply to All Tiles:** When enabled, any animation that's set up will be applied to all tiles in the layout simultaneously.
- **Animate:** This drop-down menu lets you choose between Manually Keyframing intro or outdo animations or automatically creating animations to introduce or conclude a tile. The options are:

  Manually Keyframe: In this mode, you must manually keyframe the four progress sliders below to create animated Intro and Outro animations.

  Intro Only: Animation is automatically created to bring each tile onscreen according to the types of animation you choose from four checkboxes below. Options include: Fly, Shrink, Rotate, and Fade, in any combination. A Duration slider appears that lets you choose how long the Intro will be.

  Outro Only: Animation is automatically created to send each tile offscreen according to the types of animation you choose from four checkboxes below. Options include: Fly, Shrink, Rotate, and Fade, in any combination. A Duration slider appears that lets you choose how long the Outro will be.

Intro & Outro: Animation is automatically created to bring each tile onscreen and then send each tile offscreen, according to the types of animation you choose from four checkboxes below. Options include: Fly, Shrink, Rotate, and Fade, in any combination. A Duration slider appears that lets you choose how long the Intro and Outro will be.

Fly Animation: Lets you choose a direction for tiles to fly in from and fly out to.

Shrink Animation: Lets you choose a method of shrinking out or in when the Fly Progress slider is animated.

Fly Progress: (manual key framing only) A slider that, when animated, lets you fly a tile into or out of the frame. A value of 0.000 positions the tile in its default grid position. A value of 1.000 positions the tile entirely off screen.

Shrink Progress: (manual key framing only) A slider that, when animated, lets you shrink a tile down to nothing or up to the current size. A value of 0.000 sizes the tile at its largest state. A value of 1.000 shrinks the tile to nothing.

Rotate Progress: (manual key framing only) A slider that, when animated, lets you fly a tile into or out of the frame. A value of 0.000 positions the tile in its default grid position. A value of 1.000 positions the tile entirely off screen.

Fade Progress: (manual key framing only) A slider that, when animated, lets you fly a tile into or out of the frame. A value of 0.000 positions the tile in its default grid position. A value of 1.000 positions the tile entirely off screen.

Easing & Blur

These controls appear in Tiles mode. They let you adjust the easing of the tile animation created in the previous group of controls.

- **Motion and Size Ease:** These controls set the curve used for simulated momentum in animating the Tile Position and Size keyframes of the tiles.

  None: No curves are applied. The animation snaps immediately from keyframe to keyframe.

  Linear: No easing curves are applied; motion is neither accelerated or decelerated.

  In: The animation curve starts slower and ends faster.

  Out: The animation curve starts faster and ends slower.

  In & Out: The animation curve starts slower, accelerates in the middle, and slows down at the end.

- **Animation Effects Ease:** These controls set the curve used for simulated momentum in animating the Tile Animation keyframes of the tiles.

  None: No curves are applied. The animation snaps immediately from keyframe to keyframe.

  In: The animation curve starts slower and ends faster.

  Out: The animation curve starts faster and ends slower.

  In & Out: The animation curve starts slower, accelerates in the middle, and slows down again at the end.

- **Ease Amount:** The relative strength of the animation curve in speeding up and slowing down. The values range from 0.000 to 1.000.
- **Motion Blur:** This slider controls the amount of motion blur added to the animation, in order to make it smoother and more organic looking. The values range from 0.000 (no motion blur), to 1.000 (maximum motion blur).

Global Blend

- **Blend:** This slider controls the overall opacity of the entire Video Collage effect. The values range from 0.000 (completely transparent) to 1.000 (completely opaque).

Chapter 166

Resolve FX Warp

The filters in this category let you warp the image in different ways, creating procedural or custom distortion effects, some of which can be automatically animated. The Warper plugin is a point-based free-form Warp tool.

Contents

Dent 3497
Lens Distortion (Studio Version Only) 3497
Ripples 3498
Main Controls 3498
Ripple Controls 3498
Vortex 3498
Warper (Studio Version Only) 3499
Effect Options 3500
Point Locations 3502
Onscreen Controls 3502
Waviness 3503

Dent

A warp effect that creates different types of circular bowing and folding effects.

- **DentType:** This lets you choose from six different types of “dent” warping effects. The options are Type 1, Type 2, Type 3, Sine, Cosine, and Black Hole.
- **X and Y:** Position sliders let you offset the center of the warp.
- **Size:** This lets you adjust the diameter of the warp.
- **Strength:** This lets you adjust the extent and direction of the warp, lowering this below zero “pulls” the image into the center of the effect, while raising this above zero “pushes” the image outward to buckle according to the DentType you’ve chosen.
- **Edge Behavior:** This eliminates any blanking caused by negative distortion by filling black areas in one of several user-defined ways; options include Black (do nothing and leave the blanking), Reflect, Wrap-Around, and Replicate.

Lens Distortion (Studio Version Only)

Lets you add convex or concave lens distortion to an image, to make it warp by bulging outward or bulging inward, similar to a poorly made lens. This filter could also be used in a corrective manner, to compensate for images exhibiting barrel distortion. Additionally, the amount of distortion applied to each color channel can be varied, in order to create the effect of chromatic aberration using the curvature of the distortion you’re adding for a more accurate effect.

- **Red, Green, and Blue Distortion:** These sliders are ordinarily locked together by the Gang checkbox. When adjusted as ganged, moving these sliders to the left (negative values) increases “fisheye” distortion, while moving these sliders to the right (positive values) creates an inverted “fisheye” effect that bows the image inward rather than outward. Turning Gang off lets you set the Red, Green, and Blue Distortion sliders to different values, introducing more accurately simulated chromatic aberration to the image.
- **Fine Adjustment:** This checkbox results in the distortion sliders operating within a much smaller range, enabling more precise adjustments.
- **X and Y Position:** These sliders let you change the center of the distortion effect.
- **Edge Behavior:** The options available in this pop-up eliminate blanking caused by negative distortion by filling black areas in one of several user-defined ways; options include Black (do nothing and leave the blanking), Reflect, Wrap-Around, and Replicate.

TIP: To resize a clip with an extreme distortion effect that introduces blanking around the edges of the frame, you’ll need to use the Zoom control found in the Node Sizing mode of the Sizing palette. Edit and Input sizing will only zoom the image within the border created by blanking.

Ripples

A warp effect that creates different types of ripples.

Main Controls

These controls govern the type of ripple and the quality of optional ripple shine that you want.

- **Ripple Shape:** Lets you choose from Circular, Square, Horizontal, Vertical, Exponential, Star, and Radial ripples.
- **Wave Shape:** Lets you choose from Sinusoidal, Triangular, Fresnel In, Fresnel Out, and Natural waves.

A set of Shine parameters lets you overlay a simulated shine on top of these ripples.

- **Shine:** A checkbox lets you turn this shine on and off.
- **Shine Direction:** Lets you add a light shine to the peaks of the ripples. Works best at low shine strength.
- **Vertical Shine Height:** Lets you adjust the thickness of the highlights running along the ripples.
- **Shine Size:** Lets you adjust the length of the highlights running along the ripples.
- **Shine Strength:** Lets you adjust the overall appearance of the shine.
- **Animate:** This checkbox, if checked, reveals a Speed slider that lets you set how quickly the ripple effect auto-animates the phase of the currently configured ripple effect, without the need to use keyframes.

Ripple Controls

A separate set of Ripple parameters lets you enable up to five overlapping ripples.

- **Enable Ripple:** A keyframable checkbox that will turn a particular ripple on or off.
- **X and Y Position:** Lets you change the center position of each set of ripples.
- **Amplitude:** Lets you adjust the “height” of each ripple caused by this effect.
- **Frequency:** Lets you choose how many ripples are being created.
- **Decay:** Lets you adjust the falloff of the ripple effect, where ripples gradually diminish as they reach the point of decay.
- **Phase:** Lets you adjust the phase of the ripple effect relative to the center origination point. If you want to animate a ripple simply, you can also choose to keyframe the Phase parameter to create the same effect created by the Animate checkbox above.

Vortex

Vortex begins as an S shaped warp effect, but you can adjust the parameters to create many types of warping effects.

- **X and Y position:** Two sliders let you offset the center of the warp.
- **Size:** Adjusts the diameter of the warp.
- **Angle:** Adjusts the direction and intensity of the warp effect; setting Angle below 0 twists the image to the left, while raising Angle over 0 twists the image to the right.
- **Power:** Rotates the area that’s affected to create a harder border between what is warped and what isn’t.
- **Swirl:** Intensifies the effect, twisting the image into an even tighter swirling effect.
- **Edge Behavior:** The options available in this pop-up eliminate blanking caused by negative distortion by filling black areas in one of several user-defined ways; options include Black (do nothing and leave the blanking), Reflect, Wrap-Around, and Replicate.

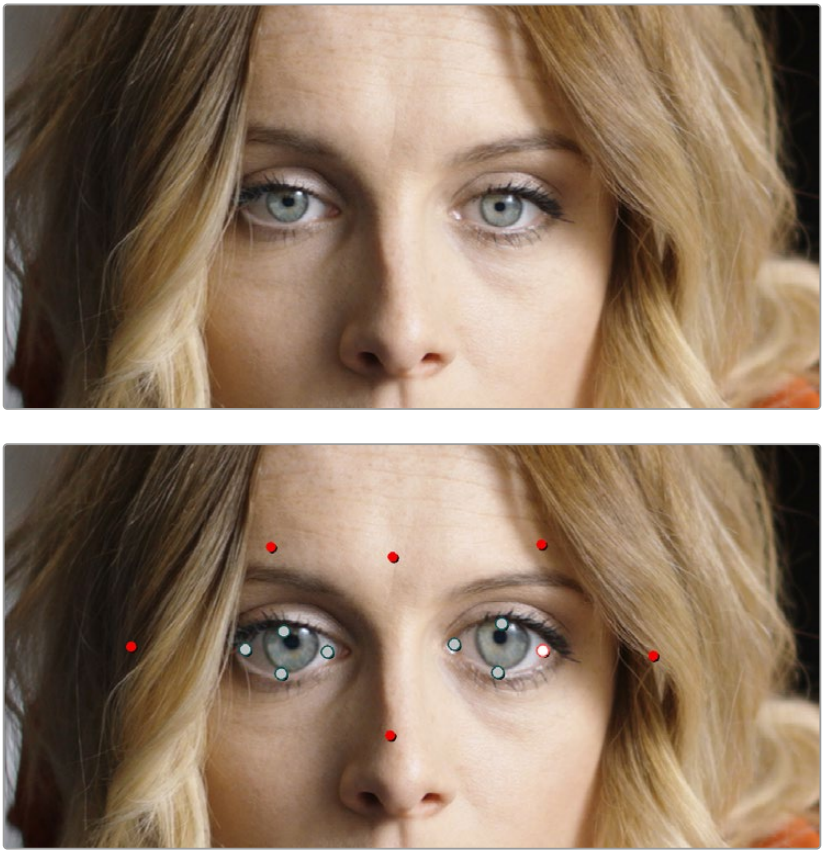
Warper (Studio Version Only)

The Warper is a free-form image warper that uses points, rather than a mesh or splines, to push and stretch features in an image as if they were on a sheet of rubber. While the Warper has a lot of options and settings, getting started is really easy.

To warp a feature of the image, just click on it to add a warp point, and drag to push that part of the image in the direction you want it to go. By default, warp points influence the entire image, which is pinned down at the corners. This system makes it simple to warp large regions of the image, such as when you want to warp an edge of the image to get rid of a boom dip. Warp points are gray unless they're selected, in which case they're white.

(Top) The original image (Bottom) The image warped with a single control point

To "pin down" parts of the image you don't want to warp, Shift-click to place limiter points (which are red, pink if they're selected). By combining warp points with limiter points, you can quickly create extremely specific warp effects to squish and stretch features in an image in any way you want.



(Top) The original image (Bottom) The image warped with control (gray) and limiter (red) points

As you work, you can Option-click any unwanted warp or limiter point to delete it. To start from scratch, you can click the Warper plugin's master reset control in the OpenFX Inspector.

Additionally, you can use the FX mode of the Tracker palette to motion track the feature you're warping. Then, by setting the Tracking pop-up menu to FXTracker, every warp and limiter point you've placed will move along with the feature you're tracking, meaning you can create warp effects that move along with someone's face, with a car driving on the road, or with something in a shot with camera motion.

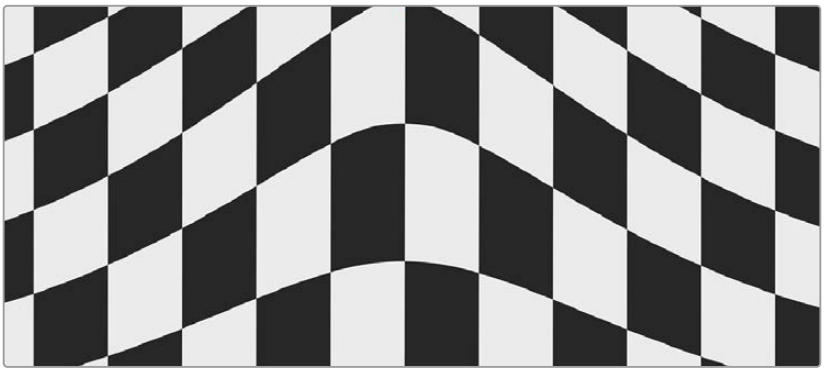
Additionally, starting in version 16, warp and limiter points can be keyframed via the Warp Scale and Warp Point Positions parameters.

Effect Options

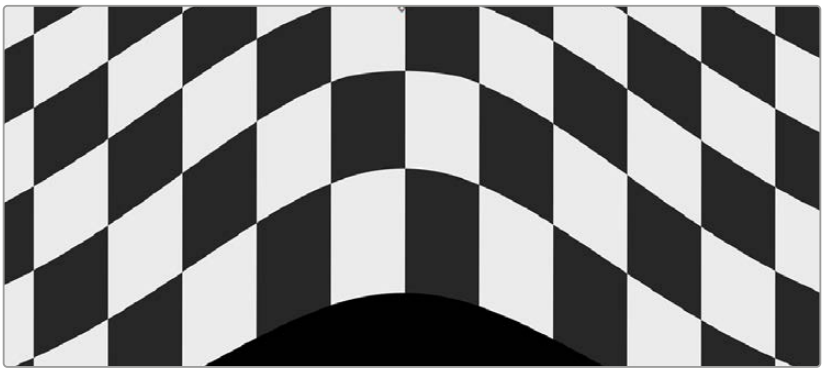
These controls affect how warp points that you add will affect the image.

- **Warp Limits:** A pop-up menu lets you choose how to treat the edges of the image when you're warping it. There are three modes:
  - Corners (the default) lock the four corners of the image in place, but allow the sides to bulge in or out as you warp and allowing blanking to creep in.
  - Edges locks the full width and height of all four edges in place as you warp, preventing blanking.
  - Distance locks parts of the image that are n pixels away, but the default setting is very permissive.
  - Manual allows the entire image to be warped without locking any part of it, allowing for extreme warps all along an entire edge of the image, but requiring you to place at least one limiter point prior to adding a warp point.

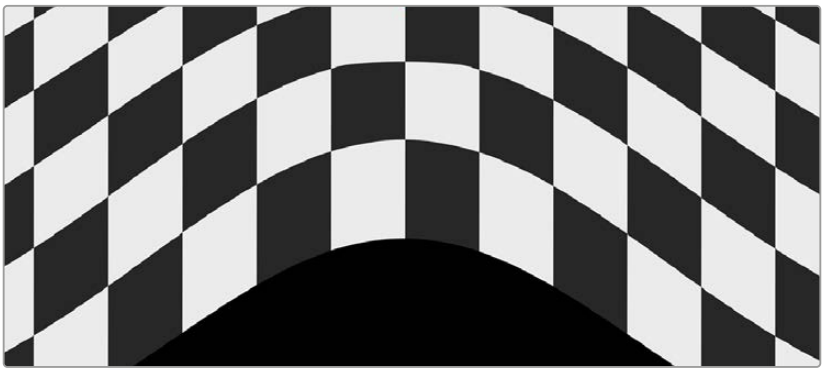
- **Warp Sharpness:** A pop-up menu lets you choose one of three methods of interpolating how the image bends around a Warp point: Sharp, Rubber-Sheet (the default), and Rounded. Sharp produces the “most pointy” warps, while Rounded produces the most gently curved warps. Rubber-Sheet strikes a balance between the two extremes.



Sharp



Rubber-Sheet



Rounded

- **Edge Behavior:** A pop-up menu eliminates any blanking caused by warping that affects the edge of the image by filling black areas in one of several user-defined ways; options include Black (do nothing and leave the blanking), Reflect, Wrap-Around, and Replicate.
- **Quality:** A pop-up menu lets you choose from among three methods of calculating the warping effect you’re creating: Faster, Default, and Better. Each choice is an obvious trade-off between image smoothness and performance.
- **Warp Scale:** This slider lets you scale the overall warp effect you’re creating. Setting this to 0.000 reduces the warp effect to nothing, while raising it to the maximum value of 2.000 doubles the warp effect. Warp Scale can be keyframed to animate the warping effect.

Point Locations

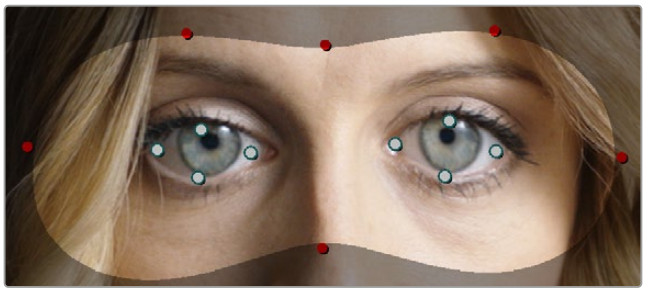
This set of controls lets you adjust how the points will operate.

- **Effect Follows:** Allows you to choose whether the points stick to the scaled content (Input and Edit Sizing), or the original frame in the timeline (Timeline Frame).
- **Manual Keyframing:** Click on the diamond to manually position the points on the frame over time.

Onscreen Controls

This set of controls lets you customize which of the Warper's onscreen controls appear, with different options that make it easier to see certain things in various situations.

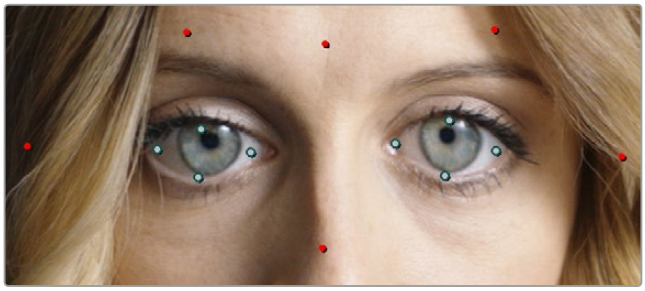
- **Render a reference grid:** This checkbox superimposes a reference grid over the image to make it easier to see what kind of warping you're applying.
- **Show Warp Boundaries:** This pop-up menu has three choices for letting you see which areas of the image will be locked off by limiter points you place in the image.
  - None hides this information and is the default setting.
  - As Border shows a red line at the boundary where warping becomes locked off.
  - As Mask dims the area that's protected from warping by limiter points.



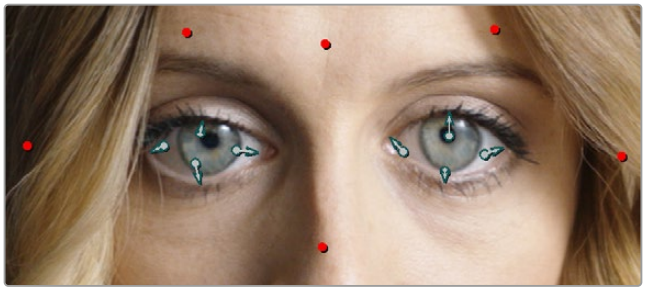
Show Warp Boundaries set to As Mask

- **Control Visibility:** This pop-up menu lets you choose whether the warp and limiter points you create are visible as you work. Show (the default) leaves all control points visible all the time. Auto Hide hides all control points whenever you're dragging one, letting you see the image as you adjust it without having control points in the way. Hide makes all control points invisible. You can add new control points, but you can't see existing control points to edit them.
- **Show:** This pop-up menu lets you choose how to represent warp points, and there are two options.
  - Warp Points (the default) simply shows warp points as gray dots.
  - Warp Vectors display pairs of controls connected by a line; a round dot shows the anchor, or the part of the image the warped portion of the image came from, and an arrow shows the destination, where you've warped that part of the image to. Seeing the anchor and destination of each warp operation can sometimes be useful when you're doing something complex.

- **Scale Controls:** Lets you adjust the size of the on-screen controls for ease of use.



Warp points



Warp vectors

- **Scale Controls:** This slider lets you shrink or grow the control points or warp vector handles to the most convenient size for the task at hand.
- **Warp Point Positions:** A parameter without any controls, save for key framing controls, that lets you keyframe the position of warp and limiter points. All points are keyframes within a single parameter and keyframe track, visible in the timeline of the Edit page, or the Keyframe Editor of the Fusion and Color pages.

Waviness

- **Waviness Type:** Lets you choose Vertical or Horizontal waviness.
- **Scale:** Lets you choose the size of the waves.
- **Strength:** Lets you adjust the amplitude.
- **Phase:** Lets you “move” the wave and is a good parameter to keyframe if you’re animating this effect manually.
- **Animate:** A checkbox that reveals a Speed slider that lets you set how quickly the Waviness effect auto-animates without the need to use keyframes.

Chapter 167

Using the Fairlight Page

The completely redesigned Fairlight Audio Core engine allows for simultaneous playback of up to 2,000 tracks. It also utilizes intelligent load balancing for maximum plugin support.

Fairlight's increased track count meets the demanding needs of both clients and immersive formats, such as Dolby Atmos. Major studio films and series television require high track counts to accommodate complex mixes and the export of multiple deliverables. Immersive formats, such as Dolby Atmos, multiply the necessary track counts with their demands for deliverables from 7.1 up to 22.2.

This chapter covers the basic user interface controls found on the Fairlight page, where they are and what they do, in order to give you an overall orientation of how to work with this integrated audio environment.

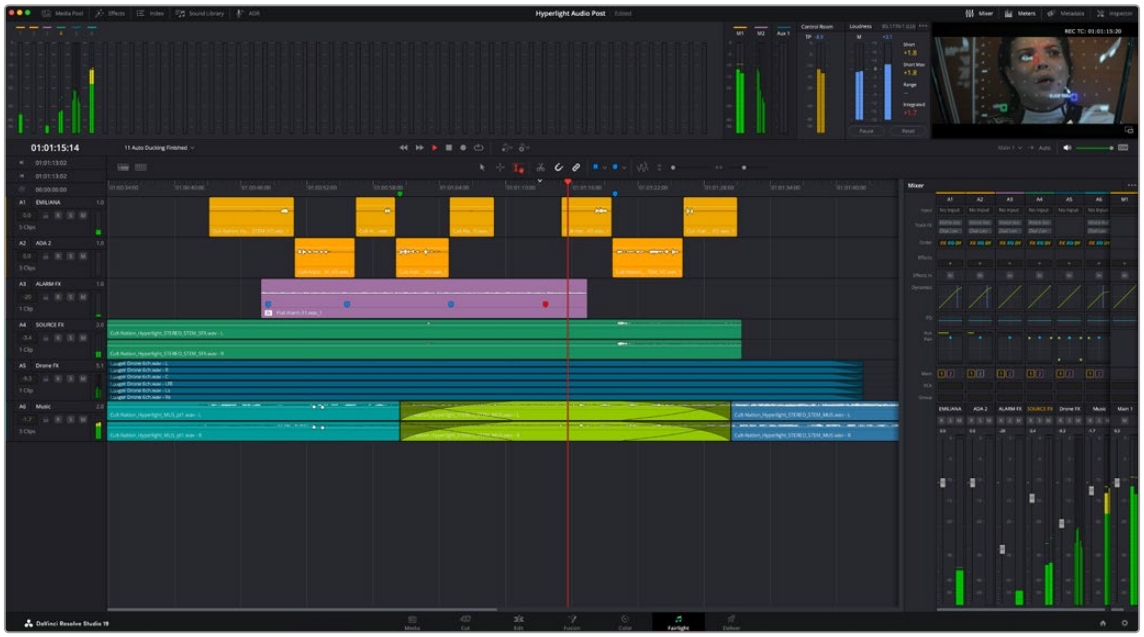
The Fairlight Page User Interface

In single monitor mode, the Fairlight page offers an optimized environment for handling your audio tracks, with an expanded mixer and custom monitoring controls that make it easy to edit and manipulate your audio media and evaluate and adjust the levels of your program to create a smooth and harmonious mix.



The Fairlight page

The Interface Toolbar

At the top of the Fairlight page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

The Interface toolbar

	Media Pool: Shows and hides the Media Pool, from which you can edit audio clips into the Fairlight page Timeline.
	Effects: Opens the Audio FX panel of the Effects Library, from which you can apply Fairlight FX, or AU or VST audio effects to clips or tracks in the Timeline.

	Index: Shows and hides the Index and its Edit Index, Tracks, and Markers panels. **Edit Index:** A list of all edit events in visible tracks of the Timeline. **Tracks:** Lets you manage the tracks of the Timeline, showing and hiding which ones you want to work with. **Markers:** Lets you see every marker in the Timeline, along with associated data. Browse through your markers all at once to quickly find the information you need.
	Groups: This button opens and closes the Groups list when you need to make simultaneous mix adjustments to a group of tracks. This list remains open when you close the Track Index or click one of the other Index tabs. For more information on working with Track Groups, *see Chapter 176, "Track Groups."*
	Sound Library: Shows and hides the Sound Library panel. There are search and filter fields to locate desired sounds and a playback window to audition the sounds prior to editing into the Timeline.
	ADR: Shows and hides the ADR panel, with tabbed controls for List, Record, and Setup, which control the functions of the ADR panel.
	Mixer: Shows and hides the Mixer to the right of the Timeline, which lets you adjust the effects and levels for each audio track to create your mix.
	Meters: Shows and hides the Monitoring audio meters and Fairlight viewer at the top of the page.
	Metadata: Shows and hides the clip Metadata panel.
	Inspector: Shows and hides the Inspector, where you can edit different clip attributes.

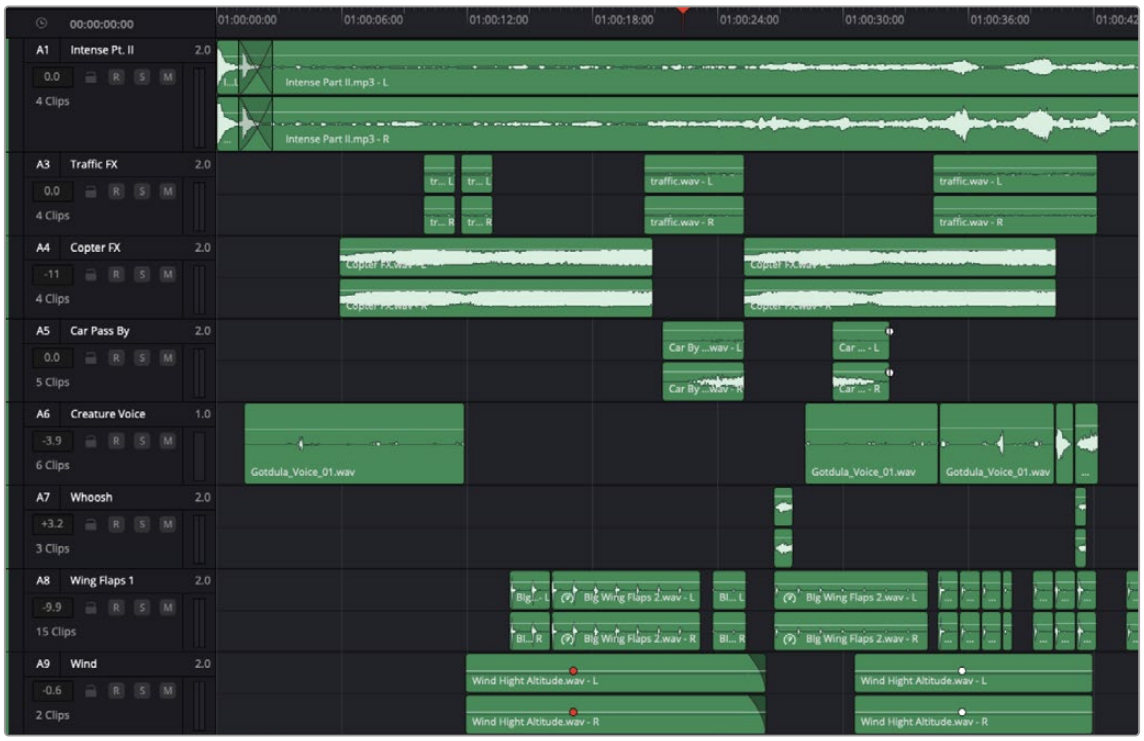
The Audio Timeline

The heart of the Fairlight page, the Audio Timeline, presents the audio channels and tracks of the currently selected Timeline. Each audio track may contain multiple lanes depending on its Track Type, or format.

The clips edited into the Timeline appear within each track, with any multichannel elements within each clip occupying as many lanes as that track type has available (for example, 2 channel stereo, or 6 channels for 5.1). At the left of each track is a header containing a number of controls.

These multi-lane audio tracks appear differently from the Edit page, which is optimized for straightforward audio-for-video editing, and shows any multichannel files on single lane tracks with composite waveforms.

The Fairlight page Timeline cannot be closed.



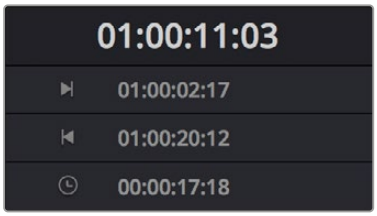
The Audio page Timeline

Controls in the Audio Timeline

The Audio Timeline has the following controls.

- **Timecode fields and Range buttons:** These fields display the current timecode value of the Playhead position along the Timeline Ruler, the Range In and Range Out points, and the Range duration.

  Clicking the Range In and Range Out buttons (to the left of their timecode fields) sets their corresponding values and locations on the Timeline Ruler.



Timecode fields and Range buttons in the Fairlight page

- **Transport controls:** Located at the top of the Timeline, this bar contains audio-specific transport controls, which differ from those found on the Media, Edit, Color, and Deliver pages due to the included recording capabilities. These controls include Fast Reverse, Fast Forward, Play Forward, Stop, Record, Loop, and the Toggle Automation and Automation toolbar display icons.

Fairlight page transport controls

- **Toggle Automation button:** Clicking this button activates automation recording and playback, and adds an Automation Follows Edit button to the Toolbar, between the Flags and Markers buttons. For more details on the Toolbar, please refer to “Toolbar,” found later in this chapter.
- **Automation toolbar:** This button opens a secondary toolbar with all the controls you need for recording mixer automation.

For more details on Automation, *see Chapter 175, “Mix Automation.”*

Fairlight page automation toolbar

- **Monitoring controls:** The three monitoring controls located at the far right of the transport controls let you quickly adjust the output volume of your mix.

  Clicking the Speaker icon mutes and unmutes the audio playback. The icon turns red when the audio is muted.

  The horizontal slider lets you gradually increase or decrease the output volume. The corresponding signal level is displayed in decibels as you move the slider.

  The DIM button lets you temporarily reduce the output volume, which is helpful if you want to have a quick chat with your client about sports or the state of the world while keeping half an ear on the mix. The slider turns yellow whenever you activate the DIM function.

The monitoring controls

- **Timeline Ruler:** The Timeline Ruler displays the program’s timecode and, in conjunction with the playhead, indicates the current frame (or sample) where you’re working in the Timeline.

  Within the Timeline Ruler, you’ll find a handle at the top of the playhead. You can move the playhead by clicking and dragging the handle.

  Markers added to the Timeline also appear in their corresponding locations within the Timeline Ruler.

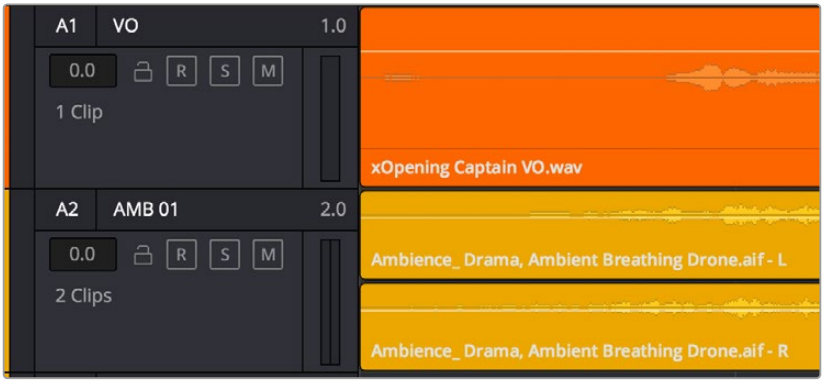
- **Playhead:** Shows the current frame and sample of playback and provides a visual representation of where you are while playing, shuttling, and jogging through the Timeline. At the same time, the large timecode display in the upper left-hand corner of the Timeline also shows the current playhead location.

  The playhead location is also a reference point for editing operations.

- **Audio tracks:** The Fairlight page supports multiple audio tracks. Each track may contain multiple lanes to accommodate the audio channels within multi-channel audio clips using track mappings such as stereo, 5.1, 7.1, Dolby Atmos, Ambisonics, or Adaptive (1–24 channels).

  Audio clips edited into the Timeline appear within the tracks, with the recorded channels occupying as many lanes as that clip has available.

  A corresponding header area containing various controls is located to the left of each track.



The Fairlight timeline is divided into tracks and lanes; track A1 is a mono track and has a single lane for mono audio. Track A2 is stereo and has two lanes for stereo audio.

Track header

The controls in the track header let you lock/unlock, solo/mute, and record-arm the track.

In addition to a level meter, the track header includes informational fields showing the track type, track number and name, track volume, and the number of clips on the track.

The track header controls of the Fairlight page timeline

- **Track color:** Each track can be color-coded with one of 16 colors, which will carry over to the Fairlight and Edit page Mixers, Tracks Index, and Audio Meters.

  To apply a color to a track, right-click the track header and choose a color from the Change Track Color submenu.

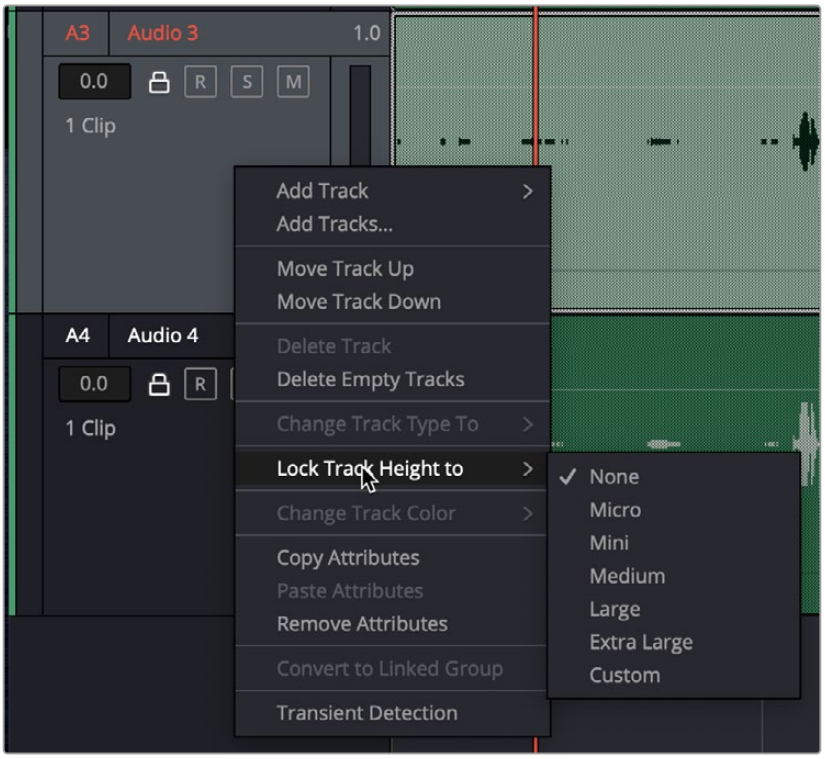
  You can apply the same color to multiple tracks by dragging over contiguous track headers or Command-clicking multiple discontiguous track headers, then selecting a color from the Change Track Color submenu.

- **Track number:** Indicates the number of each track.
- **Track name:** Each track has a name that defaults to the track number, such as Track 1, Track 2. However, you can click any track's name and edit it to be whatever you like. F

  or example, you can rename each track with the type of audio you're editing onto it, such as Production, Ambience, SFX, or Music. These track names are also used to identify each track's channel in the Mixer, in the middle of each channel strip (each channel strip's track number is simultaneously displayed at the top).

- **Audio channel type indicator:** Audio tracks also show which channel configuration that track uses, listing the number of channels for mono, stereo, 5.1, 7.1, Atmos, adaptive, and others.
- **Fader value:** A field displays the current fader setting at the position of the playhead, in dB. This value corresponds to the track's fader level on the Mixer panel. You can drag this value up or down and the fader will follow.
- **Lock Track button:** When a track is locked, clips can't be replaced, moved, or otherwise edited, although clips on locked tracks can be graded when in the Color page. The lock shows closed when track contents are locked and open when unlocked.

- **Arm button:** This button arms recording onto that track.
- **Solo button:** Disables all other tracks but the current one, enabling you to quickly hear a single track in isolation. This affects rendering, so if one or more tracks are soloed, the muted tracks won't be output or rendered.
- **Mute button:** Temporarily disables audio on that track so it's not monitored or output. This affects rendering, so if one or more tracks are muted, they won't appear in the rendered output.
- **Audio meters:** Each track has audio meters in the track header that let you see levels during playback.
- **Toolbar editing tools:** The toolbar contains both modal and command buttons to let you work on your projects. More detail on these appears in the following section.
- **Vertical and horizontal scroll bars:** If your project is longer than the current width of the Timeline, or the number of audio tracks is taller than the current height of the Timeline, these scroll bars let you drag to navigate around your program. When the view is scrolled horizontally, the playhead moves along with the track waveforms, so it may temporarily move out of view. If you start playback, the playhead jumps back into view. You can also scroll vertically using the scroll wheel (or other scroll control) of your mouse or other pointing device and can scroll horizontally by holding the Command key down while using your scroll control.
- **Individual Timeline track resizing:** Any track in the Timeline can be individually resized by right-clicking anywhere within that track's header control area and choosing a track height from the Lock Track Height To submenu of the contextual menu. You can choose a fixed size including Micro, Mini, Medium, Large, Extra Large, and Custom. When you choose a fixed track height, vertical zooming no longer affects that track until you change that track's "Lock Track Height to" option back to None. You can also highlight several or all tracks and set the track height to one size. All highlighted tracks will change to that particular size unless changed again, either globally or individually.



Resizing an individual audio timeline track using contextual menu options

Zooming Audio Waveform Height

You can zoom into or out of the audio waveforms shown in each clip of one or more tracks, to make them taller or shorter, or you can reset them to their default sizes. This doesn't change the audio levels of clips in affected tracks, it just lets you make the audio waveforms easier to see.

To zoom audio waveform height using your scroll wheel:

Hold down Command-Option, and roll the scroll wheel or control up or down to resize all waveforms in all tracks.

You can also use commands that are accessed in the top menu View > Zoom Audio Waveform for any track on the Timeline. You can select one or multiple tracks to resize their waveforms all at once. There are three sets of commands in the menu:

- Reset
- Zoom Increase Height
- Zoom Decrease Height

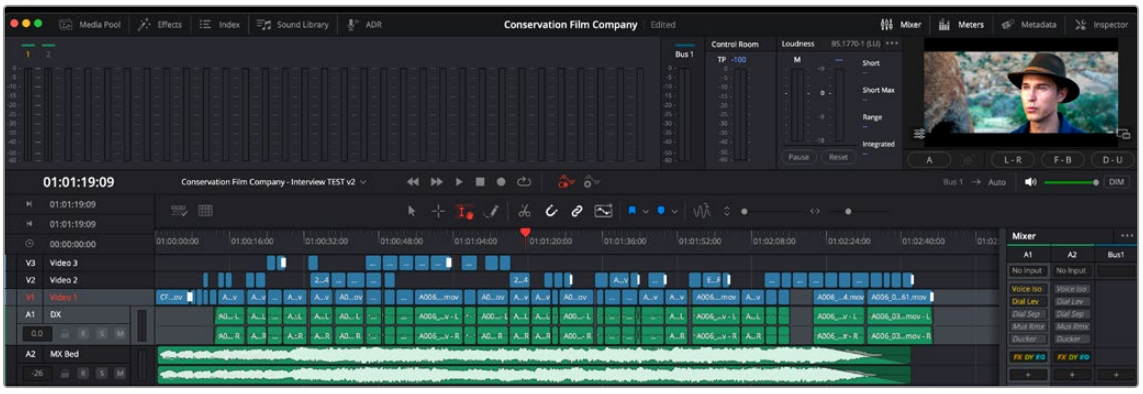
Right-clicking any clip in the Timeline allows you to access the Track Waveform Zoom submenu with even more zoom options.

Smart Zoom Track Height

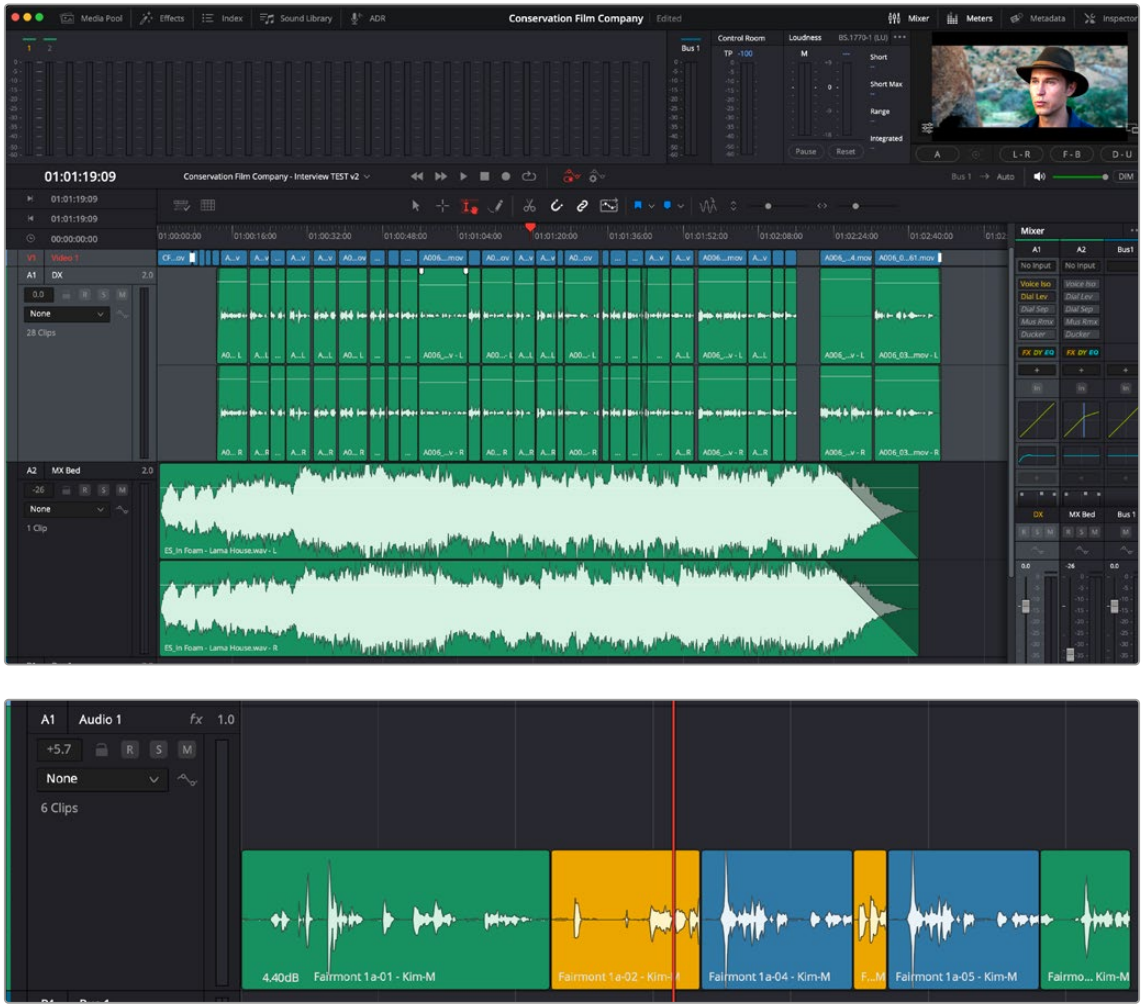
When you select a track in the Timeline or Mixer and press Command-Option-E, Smart Zoom increases the track height and centers your selection to occupy the whole viewable area of the Timeline. Once you've finished your edits, press Command-Option-E again to close Smart Zoom.

As with other Da Vinci Resolve key commands, you can re-map Smart Zoom in the Keyboard Customization dialog.

> For more information on Keyboard Customization, *see Chapter 4, "System and User Preferences."*



Standard Timeline view



Smart Zoom Timeline view

Audio Editing Modes

The Fairlight page has two audio editing modes: Overwrite Mode and Layered Audio Editing Mode.

Overwrite Mode

As the name suggests, if one a portion of a clip overlaps another clip during an edit, the area that is affected on the underlying clip is non-destructively deleted to accommodate the incoming clip. If the overlapping clip is moved or deleted, the underlying clip remains truncated.

Any area that is removed by this process is still present in the original clip and can be exposed by trimming the start or end (depending on what you've affected).

Overwrite is the default mode and is best for most generalized editing.

(Left) Overwrite edit showing original clips, (Right) Right hand clip dragged left

Resulting overlap

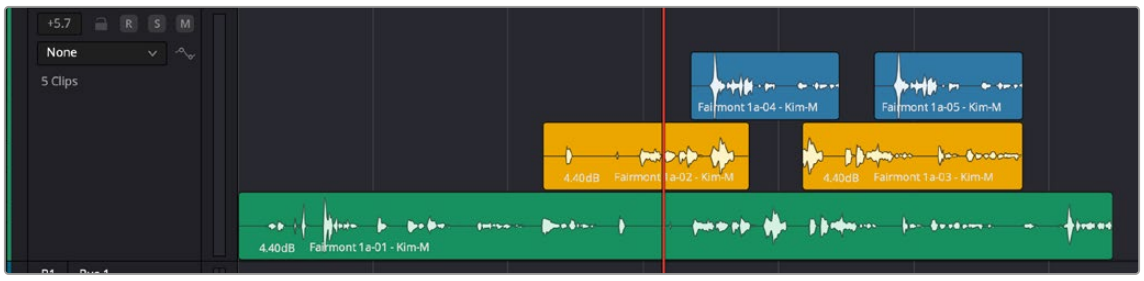
Layered Audio Editing

Layered Audio Editing is a special audio editing mode that lets you superimpose multiple audio clips in the same track, with audio clips edited into the top layers muting overlapping sections of audio clips appearing on lower layers. With layered audio editing enabled (Timeline > Layered Audio Editing), superimposed audio clips are treated similarly to superimposed video clips that have opacity set to 100%, with clips on top obscuring (or muting) clips underneath. You can separately toggle this on and off in the View menu > Show Audio Track Layers.

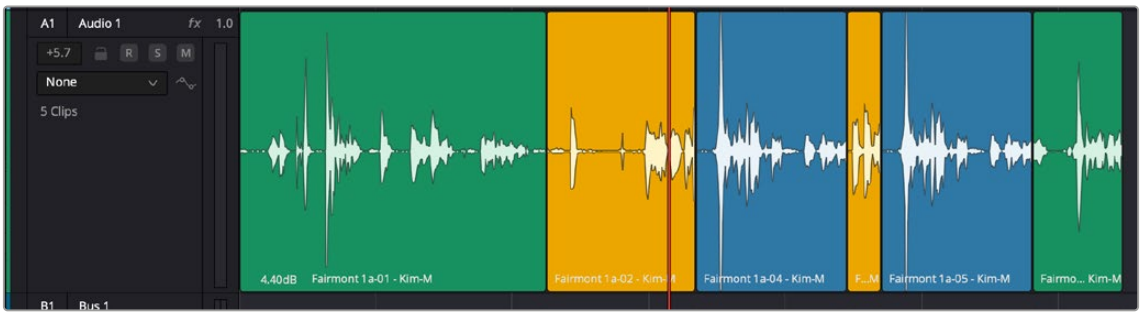
This mode is very useful for any situation where you're combining segments of multiple takes together ("comping") to create a single voiceover, audio vocal track, ADR, or dramatic performance, as you can choose which segments to use via their superimposed position in the stack of clips appearing in that track, while preserving the other takes underneath in case you might want them later.

However, it's important to understand that if you delete any clip on a layer that is "above" another, the lower layer will then "poke through." This can involve extra housekeeping when editing and is one of the reasons that Overwrite Editing mode is the default mode.

TIP: Layered Audio Editing mode can be used on audio tracks on the Edit page as well.



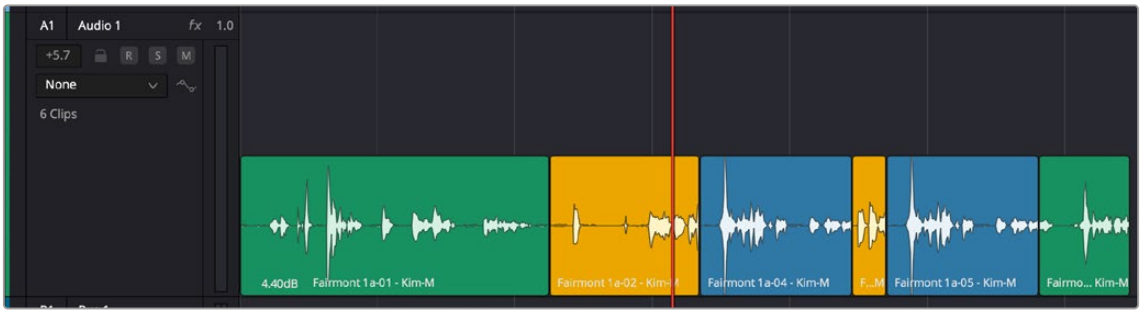
Layered Audio Editing and Show Audio Track Layers enabled



Layered Audio Editing with Show Audio Track Layers disabled. All layers are folded into a single view.

Flatten Audio Layers

After working with Layered Audio Editing, it can be useful to create a “comp” (composite) of a performance in order to have a single element that reflects the final desired result. Timeline > Flatten Audio Layers allows you to create a single edit without layers where the clip boundaries are preserved. Choosing this command will cut across each layered clip at the in/out points and flatten them into a single layer.



After choosing Flatten Audio Layers, audio layers showing (so blank space above)

If you are exporting to an AAF, you’ll want to turn off layered audio editing, as only the first, lowest layer is exported. If you had already been using layered audio editing, you can first use Flatten Audio Layers, then perform your AAF export. Keep in mind that if you have created any layered crossfades, only fades on the incoming clip are retained.

Switching Among Multiple Timelines

Timelines can be organized like any other clip in the Media Pool. To open or switch among timelines, use the following procedures. Each Timeline retains the view settings last made within it, including track heights, zoom settings, etc.

To switch timelines, do one of the following:

- In the Edit, Cut, or Fairlight page Media Pool, double-click a timeline.
- In the Edit page Timeline Viewer, choose a timeline from the Timelines dropdown menu at the top of the viewer.
- In the Color page, choose a timeline from the Timelines dropdown menu at the top of the viewer.
- In the Fairlight page, choose a timeline from the Timelines dropdown menu to the left of the transport controls.

Toolbar

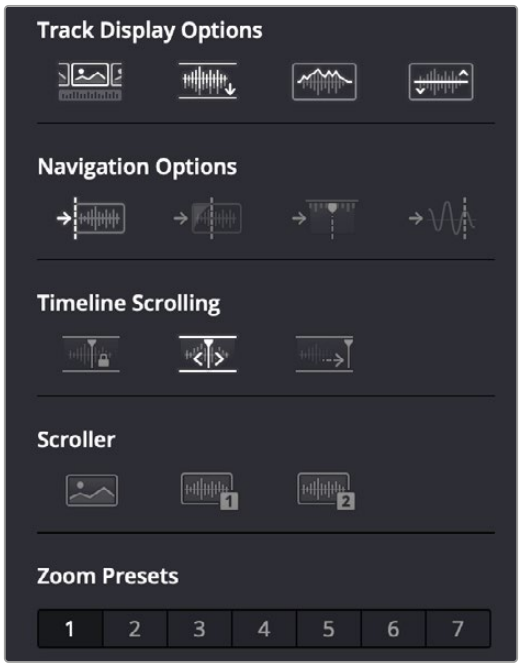
The Toolbar has buttons that let you choose modes of functionality and other buttons that let you execute commands such as placing markers and flags.

Icons in the Fairlight Page toolbar when the Automation button is highlighted in the transport bar

	Timeline View Options dropdown menu: Contains a variety of controls that allow you to customize the display of clips and set navigation and scrolling options in the Timeline.
	Grid View Options dropdown menu: Contains controls to customize the timeline grid, allowing you to view reference lines or align clips to timecode or musical beat locations.
	Pointer Mode: The default mode in which you can move and resize clips in the Timeline, roll edits, and do other basic editing tasks. While this mode can be used with the pointer, it's designed for letting you make automatic selections of clips at the position of the playhead in selected tracks, using keyboard shortcuts or the Fairlight Editing console.
	Range Mode: An editing mode in which you can select partial regions of one or more clips for partial editing. It's designed for letting you make automatic selections using In and Out points to define regions of selected tracks, using keyboard shortcuts or the Fairlight Editing console.
	Focus Mode: In Focus mode you can access Multi Tool behavior depending on cursor position: **The Selection tool (I-beam):** Appears when you move the cursor over the upper area of the waveform track "lane," and lets you make time range selections of clips or automation keyframe data (depending on the track view). **The Hand tool:** Appears when you move the cursor over the lower area of the waveform lane, and lets you select a clip or clips by clicking, move them by dragging, or apply Cut, Copy, and Paste operations. This tool is available in the other modes as well. **The Trim tool (Up/Down arrows):** Appears when you move the cursor close to the clip gain line, and lets you trim the automaton curve for clip gain or keyframe levels. When trimming an automation parameter, a tooltip shows the level along with the delta to the original value. Trim tool cursors for trimming clip boundaries to trim clip start or end, or perform rolling trims are also available. This tool is available in the other modes as well.
	Pencil: A tool that lets you write automation data using the pointer as a pencil. The Pencil tool appears when automation is enabled.
	Razor (Scissors): Click to add a cut to every clip on an unlocked track that intersects the position of the playhead.

	Snapping: Enables or disables clip snapping. When turned on, clip In and Out points, markers, and the playhead all snap to one another for reference while you're editing.
	Linked Selection: When you select an edit point with both video and audio components, and Linked Selection is enabled, both the video and audio edit points are selected, so when you apply a video transition to an edit, a crossfade is added to the audio. Also lets you link together any otherwise unrelated audio clips to perform edit operations (for example, trimming) to any linked clips at one time.
	Automation Follows Edit: Enables or disables mix automation that is unique to a timeline to be embedded into the clips so that when cutting and pasting new instances of them in the Timeline they retain their levels, panning, filter settings, etc. This is extremely useful when using multiple instances of the same audio clips throughout an edit. The Automation Follow Edit button appears when automation is enabled, and is enabled by default.
	Flag Clip/Flag Colors dropdown menu: Flags identify clips, and indicate all clips that correspond to the same item of media in the Media Pool. Clips can have multiple flags. Clicking the Flag button automatically adds a flag to whichever clip is currently selected in the Timeline. A dropdown menu lets you choose flag color, and has a choice to clear all flags from the currently selected clip (if one is selected) or clear flags from the entire timeline (if no clip is selected).
	Add Marker/Marker Colors dropdown menu: Markers identify specific frames of individual clips or timelines. If a clip is selected in the timeline, clicking the Add Marker button adds a marker to the clip at the position of the playhead in the Timeline. If no clips are selected, clicking the Add Marker button adds a marker to the timeline ruler at the position of the playhead. A dropdown menu lets you choose marker color, and has a choice to clear all markers from the currently selected clip (if one is selected) or clear markers from the entire timeline (if no clip is selected).
	Transient Detection: Enables transient detection for all clips on a given track. Once enabled, a transient button appears on tracks to enable the transients on a track's clips to be easily identified and navigated. When the Jump to Transient button is enabled, the Up and Down arrow keys navigate to transients within a clip.
	Vertical Slider: Lets you adjust the vertical zoom level of tracks.
	Horizontal Slider: Lets you adjust the horizontal zoom level of the Timeline.

Timeline View Options



Selecting the Audio Timeline View options

Track Display Options

	Video Tracks: This button lets you display or hide the video tracks in the current Timeline, for use as a reference while you work.
	Full Waveforms: This button lets you toggle full waveforms on and off, optionally hiding the divider bar that keeps the waveform separate from the file name area of each audio clip, so the waveform occupies the full space of each audio bar in the Timeline.
	Waveform Borders: This button lets you toggle waveform outlines on and off, drawing a dark border around the edges of each waveform to make them easier to see.
	Gain Line: This button lets you toggle the clip gain indicator line on and off. Also available in the Fairlight Menu > Show Clip Gain Line.

Navigation Options

	Jump to Clip: When toggled this lets you jump from clip to clip using the Up or Down Arrow keys.
	Jump to Fade: When toggled this lets you jump from fade to fade using the Up or Down Arrow keys.

	Jump to Marker: When toggled this lets you jump from marker to marker using the Up or Down Arrow keys.
	Jump to Transient: When toggled this lets you jump from transient to transient using the Up or Down Arrow keys. Transient Detection must be turned on in the Timeline and the track for this navigation.

Timeline Scrolling

	Fixed Playhead: This button lets you set the playhead to be fixed so that during playback the tracks scroll past the playhead as it remains in place, which is useful when working with the Fairlight control surface.
	Page Scrolling: This button lets you set the playhead to scroll to the end of the current Timeline view and then start a new page at the end of the Timeline play. The rate of the page turn is dictated by zoom level of the Timeline.
	No Scrolling: This button sets fixes the Timeline in place so that it will not update with the playhead. Depending on the zoom level, it is possible that the playhead will play offscreen with no timeline updating

NOTE: These options are also available in the View menu > Timeline Scrolling.

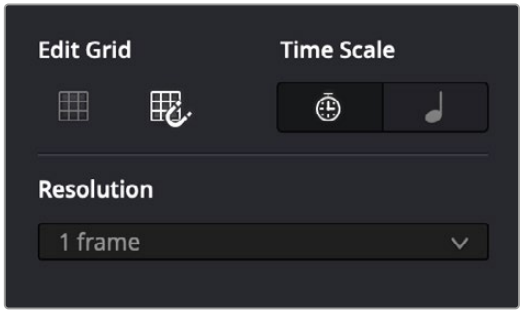
Scroller

	Video: This button lets you see video tracks scrolling in the bottom of the Fairlight timeline with the option of low, medium, or high viewing of the video media immediately surrounding the playhead.
	Audio 1: An audio scroll bar and zoomed-in visual reference for the audio media immediately surrounding the playhead. A dropdown menu allows for the choice of what audio track will scroll.
	Audio 2: An additional audio scroll bar and zoomed-in visual reference for the audio media immediately surrounding the playhead. A dropdown menu allows for the choice of what audio track will scroll.

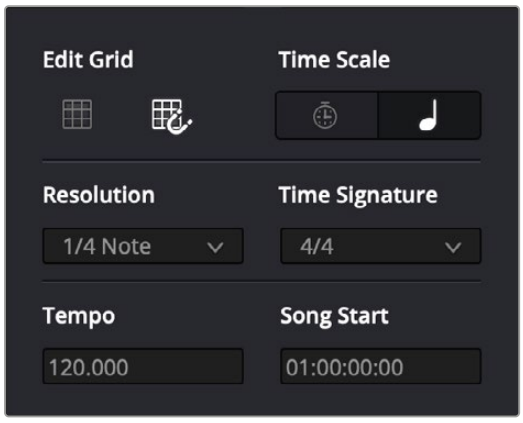
Zoom Presets

	Presets 1-7: These buttons let you choose from one of seven zoom levels.

Grid View Options



Selecting the Grid View options;
Timecode Time Scale options shown



Tempo Time Scale options shown

Edit Grid Options

	Show Grid: When toggled, this shows or hides the grid line on tracks under the Timeline.
	Snap to Grid: When selected, inserting, moving, or trimming clips on tracks snap to the nearest grid line.

Time Scale Options

	Timecode: When selected, the grid follows Timecode according to the selected resolution.
	Tempo: When selected, the grid follows bars and beats.

Timecode Grid Resolution

When the Timecode Time Scale option is enabled, the Grid follows the selected Timecode Grid Resolution. The Timecode Grid resolution options include: 1 second, 1 Frame, 1/2 Frame, and 1/4 Frame.

Tempo Grid Options

The following Tempo Grid options determine grid behavior when the Tempo option is selected:

- **Resolution:** Lets you select the desired Grid resolution according to bars and beats: Bar, 1/2 Note, 1/4 Note, 1/8 Note, 1/16 Note.
- **Tempo:** Lets you enter the tempo in BPM.
- **Time Signature:** Lets you select one of the following as the time signature: 4/4, 3/4, 6/8.
- **Song Start:** Lets you enter the Song Start Timecode location.

Setting the Tempo Grid Start

To set the Tempo Grid start location:

- Right-click at the desired location on the Timeline ruler.
- Choose Set Tempo Grid start.

  The first bar and beat of the tempo grid moves to that location.

Setting the Tempo Grid start location

Setting the Tempo Grid from a Range Selection

Tempo Grid Setup window

To set the Tempo value for the Tempo Grid from a range selection:

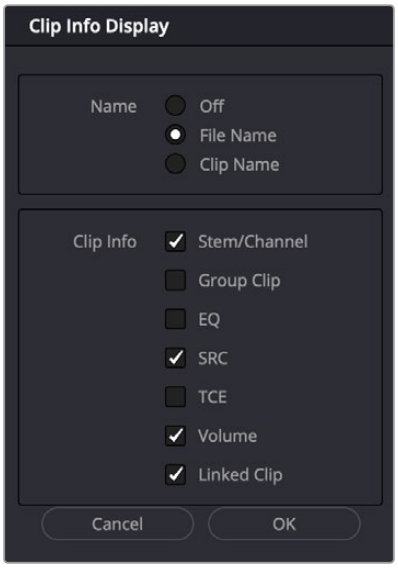
- Make a range selection in the Timeline.
- Right-click anywhere in the Timeline ruler, and choose Set Tempo Grid BPM from the contextual menu.
- In the resulting Tempo Grid Setup window, enter the number of bars in the selection.
- If desired, select Set Start from Playhead.
- Click Set Tempo From Range.
- Close the Tempo Grid Setup window.

The tempo in the Tempo Grid Options settings updates accordingly.

TIP: When setting the tempo based on a range selection, choose a section of the music where it is easy to count out the bars/beats to set the range.

Customizing Clip Display in the Timeline

Choose Fairlight > View Clip Info Display to open a dialog where you can customize what information is shown at the bottom of each clip in the Fairlight timeline. This dialog has options for viewing no clip name, the file name, or the clip name, and for choosing from among a variety of metadata that you might want available to view as you work with clips in the Timeline.



Selecting the audio clip view options

Customizing the Timeline's Display

There are a variety of ways you can customize the Timeline to better see what you're working on.

Playhead Modes

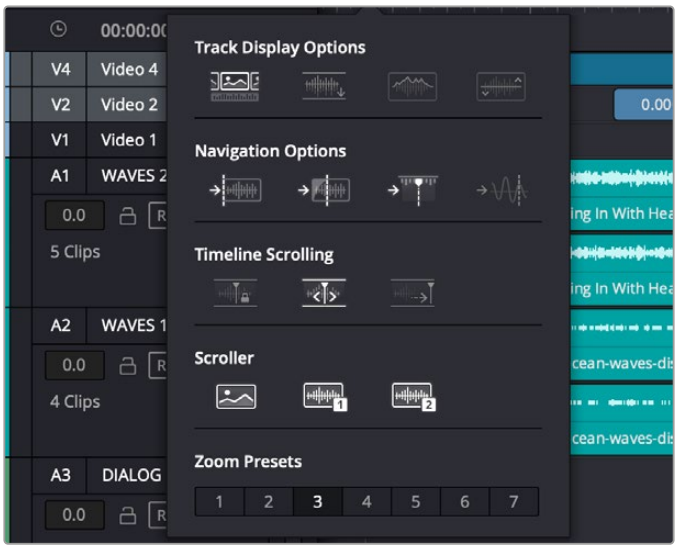
There are options for Page Scrolling ("Page") and No Scrolling ("Disabled") as outlined in the Timeline View Options section above. There is also the option for turning on the Fixed Playhead mode when you are not using Focus mode. This is available in the Timeline View Options dropdown menu, or choosing View > Timeline Scrolling > Fixed. When enabled, the playhead remains fixed in place, and the Timeline scrolls underneath it as you use the transport controls or JKL to play, shuttle, or scrub forward or back.

NOTE: Fixed playhead scrolling is not currently available when using Focus mode.

Also, please keep in mind that when you have changed DaVinci Resolve > Keyboard Customization from the default DaVinci Resolve mapping to a different mapping, many default key commands are altered. For instance, the Pro Tools Keyboard Customization does not offer JKL transport.

Visible Video Tracks

A checkbox in the Timeline View Options dropdown menu of the toolbar lets you display small height video tracks in the Fairlight timeline for reference. This can be very useful as you can see which audio clips correspond to which video clips. The video clips can also be used as snapping targets for positioning audio.



Showing video tracks on the Fairlight page

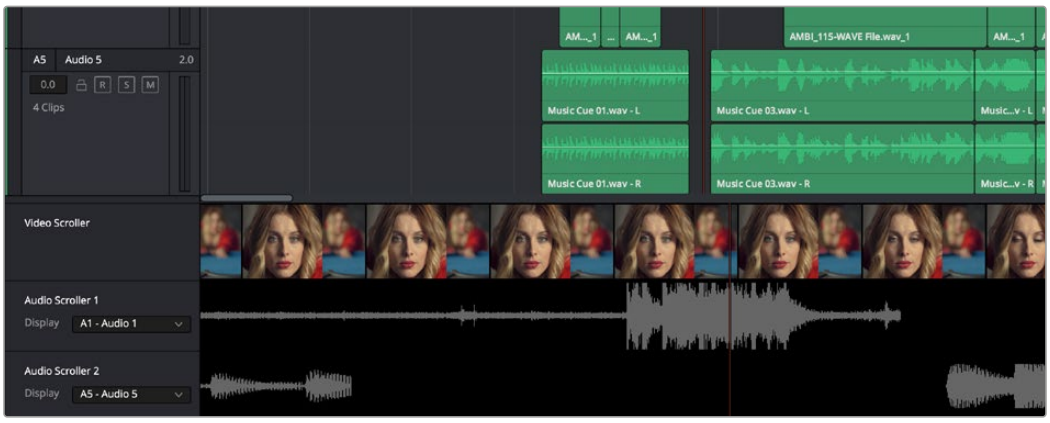
When the Video Tracks option is on:

- The Track Index can be used to choose which video tracks are visible.
- The video track(s) can be edited, both placement and clip trimming.
- Editing an embedded clip that contains both video and audio will add a clip with both audio and video in the appropriate corresponding tracks.

If the Video Tracks option is disabled, adding a clip with both video and audio to the timeline will add only audio to the corresponding tracks.

Video and Audio Scrollers

Checkboxes in the Timeline View Options let you optionally show one Video Scroller and up to two Audio Scrollers at the bottom of the Fairlight timeline.



Video and Audio Scrollers at the bottom of the Fairlight timeline

At the default Low zoom level, the Video Scroller provides a scrollable frame-by-frame filmstrip view of the video of your program, where one frame of the scroller equals one frame of your video.

Each of the two Audio Scrollers, on the other hand, let you focus on a continuous waveform view of a particular audio track. Choose which track is visible in an Audio Scroller via the dropdown menu in the Timeline header.

Audio Scrollers showing the dropdown menu that selects which track they display

What Are They Used For?

The Audio Scrollers always provide a zoomed-in view of specific audio tracks that you're focused on, regardless of the zoom level of the Timeline tracks above. This means you can focus on subtle details of the audio of one or two tracks that you're working on, while the rest of the Timeline shows you the overall stack of tracks with clips that are playing together at that moment.

Meanwhile, the Video Scroller always shows the exact frame of video that corresponds to the current moment in time, so it's an aid to precision editing involving frame-specific adjustments.

Additionally, both the filmstrip and waveform viewers scroll continuously during playback, giving you a preview of what visual actions and audio cues are coming a few moments forward in time that you can refer to while performing automation or recording foley.

Repositioning the Scroller Playhead

While the scrollers are visible, the Scroller playhead can be dragged to the left or right in the Timeline to give you more or less preview room to the right.

Zooming the Video Scroller

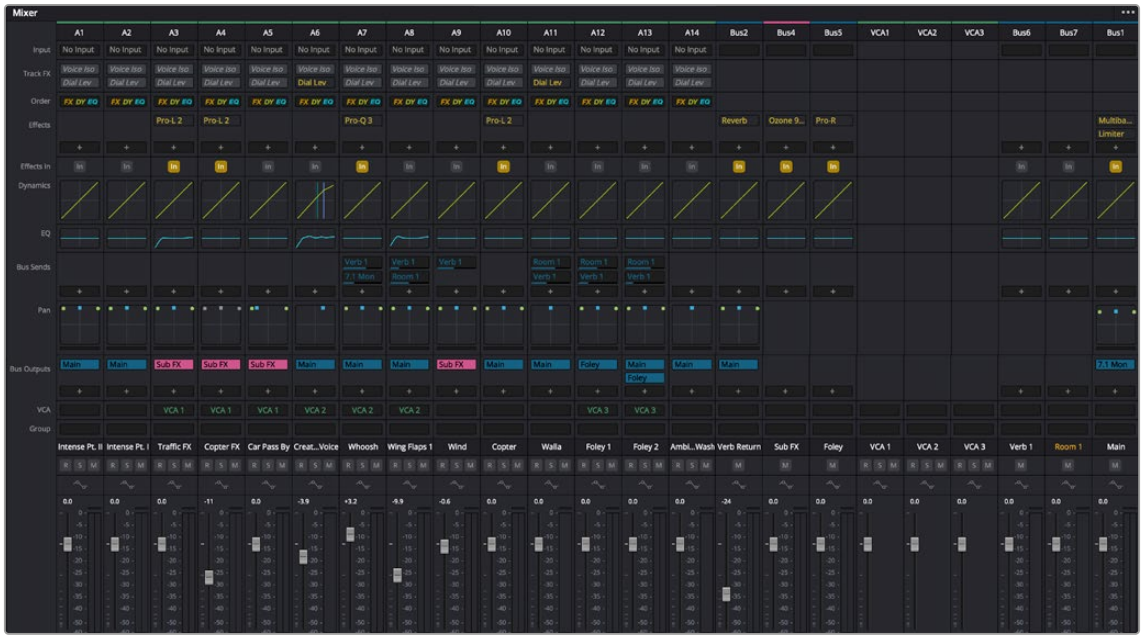
Right clicking on the Video scroller lets you choose a Low, Medium, or High zoom level. At Low, you get a frame-by-frame view of the program that feels like scrolling a strip of film on a Steenbeck flatbed editor. At Medium and High, you get a progressively abbreviated film strip that scrolls more quickly.

Scrolling the Fairlight Timeline Using the Scroller Tracks

Dragging the scroller tracks to the left or right smoothly scrubs through the Timeline in greater detail, regardless of the zoom level of the Timeline tracks above.

Mixer

The Audio Mixer provides a set of graphical controls you can use to assign track channels to output channels, adjust EQ and Dynamics, add filters and Fairlight FX, set levels and record automation, pan stereo, surround and immersive audio, and mute and solo tracks.



The Audio Mixer, with channel strips corresponding to the tracks in the Timeline

The Audio Mixer exposes two sets of channel strips with controls that correspond to the tracks in the Timeline. By default, the leftmost set of channel strips expose one set of controls for each track in the Timeline, while the rightmost set of channel strips expose another set of controls for each bus you've created to manage signal flow from the audio tracks to submixes and desired outputs.

> **TIP:** You can right-click on a the number at the top of mixer channel strip to copy/paste settings, and also copy/past settings within the mini views of the channel dynamics and EQ as well. Also, effects plugins (Fairlight FX, AUs and VSTs) have local 3 dot Options menus at their top right that allow you to copy/paste settings.

- **Track color:** Each track can be differently color-coded using the right-click contextual menu on a track in the Timeline or Tracks Index, to help you keep organized.
- **Track number:** The number of the Timeline track corresponding to each channel strip appears here.
- **Input:** A dropdown menu that lets you patch inputs, busses, utility signals, and configure the input settings of audio signals routed through Blackmagic Design or other hardware interfaces.
- **Track FX:** This channel strip section offers specialized built-in Fairlight FX plugins, routed directly from disk and then onwards to other effects processing. The available Track FX are the Voice Isolation, Dialogue Leveler, and the new Dialogue Separator, Music Remixer, and Ducker plugins.

  Voice Isolation is a DaVinci Neural Engine AI effect that is only available in DaVinci Resolve Studio. For details on Track FX, *see Chapter 178, "Fairlight FX."*
- **Order:** A dropdown menu that lets you choose the order of processing per track of the EQ, Dynamics, and Effects.

- **Effects:** Fairlight FX, VST, and Audio Unit effects that you apply to tracks from the Effects Library appear here, with controls for enabling/disabling each effect, opening an effect's floating user interface or Inspector controls, and deleting that effect.
- **Effects In:** A button to globally mute or enable all insert effects on a track (Fairlight FX, AU or VST). Track FX and the built-in channel dynamics and EQ are not affected by this control.
- **Dynamics:** Double-clicking exposes a set of dynamics controls with three sets of controls corresponding to an Expander or Gate, a Compressor, and a Limiter that can be used separately or in concert to manage the dynamics of the audio on that track.

The channel strip Dynamics control window

- **EQ:** Double-clicking exposes a four-band parametric equalizer, with additional High and Low Pass filters, that has both graphical and numeric controls for boosting or attenuating different ranges of frequencies of audio on each track. You can select from among four types of EQ filtering from the Equalizer Type dropdown menu, with options for Earth (the default), Air, Ice, and Fire. These four equalizer types affect the Curves aspect and Q-factor of the transfer function. Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band), with the available controls for each band of EQ change depending on the filter type.

The channel strip EQ window

- **Bus Sends:** Click the + sign to add bus sends. Bus sends are only available if there are two or more available busses. Creating a bus send requires at least one additional bus other than the main output bus.
- **Pan:** A pan control compatible with stereo and surround panning. You can drag within this control to adjust pan, or you can double-click to expose a pan window. What controls are available in the pan window depend on the mapping of the audio track, but both stereo and surround panning controls are available, with corresponding numeric controls.

The Pan control window

Option-double-clicking on the Pan control of the Mixer opens an alternate 3D Audio Pan window. Whereas the regular Pan window lets you do stereo and conventional 5.1 and 7.1 surround panning, the 3D Audio Pan window lets you do the kind of spatial audio positioning enabled by advanced surround formats, such as Dolby Atmos, Auro 3D, and NHK 22.2.

The 3D Pan window

- **Bus Outputs:** These buttons let you assign a track or bus to one or more of the output busses.
- **VCA:** These buttons let you assign that track's channels to VCAs 1-10, or assign from the larger pool of 128 total available VCAs via a secondary dialog box.

- **Track name:** This mirrors the track name found in the header controls of the Timeline. You can customize a track's name in the Mixer by double-clicking and typing in the name field.
- **Arm, Solo, and Mute buttons:** Identical to the controls found in the track header controls of each timeline audio track. Arm enables recording for a track. Solo lets you mute all other tracks in order to play that track in isolation (along with any other Soloed tracks). Mute disables audio playback from that track. These controls are also available the Tracks Index.
- **dB display:** Shows you the volume level, in decibels, that track is currently set to.
- **Automation Arm:** Arm automation control per track. When enabled, will record automation in Latch mode when the transport runs. The control also shows red when a fader is moved. Automation can also be set to "Safe" or "Off" by right-clicking on this control.
- **Level Meter:** This is a real time indicator showing a track's signal level from -60db to 0db. The display and decay characteristics for audio metering can be set in Project Preferences > Fairlight > Audio Metering.
- **Fader:** Each track's main vertical faders let you adjust the level of that track and perform automation recording. Double-clicking the fader handle will reset it to the default level of 0. Holding the Shift key when adjusting a fader allows fine control of level with .1 dB resolution.

TIP: You can quickly assign bus routing, VCAs, plugins, or enable/disable automation safe on or off for a selected group of channel strips, or to all channel strips by holding down the Option key (Mac) or the Alt key (Windows) for all selected tracks or Command-Option (Mac) or Control-Alt (Windows) for all mixer channel strips prior to performing the operation. These shortcuts can save a lot of time in your workflow.

The Monitoring Panel

The Monitoring panel that runs along the top of the Fairlight page shows all of the audio meters corresponding to the tracks in the Timeline, as well as the Master Output meter, Control Room meters, and a video viewer.

The Monitoring panel

At left, a row of audio meters corresponds to the channel strips of the Mixer, one meter for every audio track in the Timeline. Each track meter displays the number of channels that corresponds to that track's audio format, with mono tracks having a single audio meter, stereo tracks having two, 5.1 tracks having six, and so on. All of these track and bus meters (with the exception of the Loudness meters) display both peak and RMS (root mean square) levels against a dB scale.

To the right of the Track meters are the Bus meters, where all busses appear separated by type, each displaying a meter with the number channels that corresponds to the bus's audio format. This way you can see the sum of all tracks that have been routed to a particular bus.

The last set of meters, to the right of all others, are the Loudness meters, which consist of two sets of meters and a numerical readout section. The Control Room meter reflects that main output level from the program and the Loudness meter measures the mix's loudness according to the user's chosen scale. This lets you keep track of the "integrated loudness" of the overall mix, which is the standard that all contemporary mixing specifications refer to when specifying client deliverables.

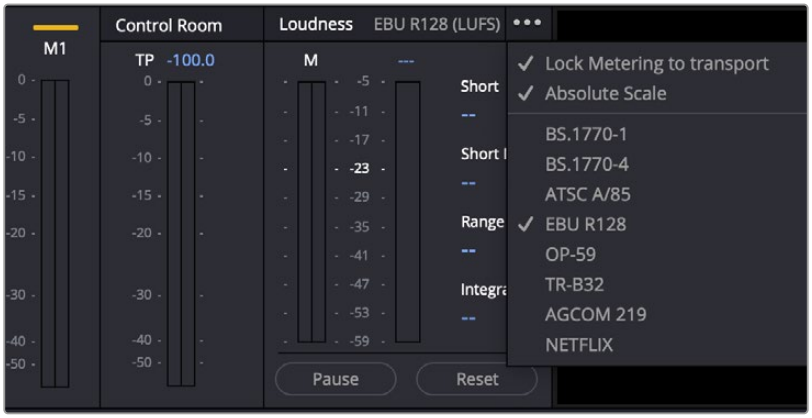
The height of the monitoring panel can be adjusted by dragging the bottom of the panel.

Absolute and Relative Measurement Scales

While some users prefer to measure their levels to correspond to a relative scale of "0," similar to a VU meter where the needle rides above the "0," others want to see the absolute measure of the amplitude in LUFS and true peak. By default, the Loudness meter is set to relative scale, but you now have the option to choose between relative scale and absolute scale in the Loudness meter.

Relative scale in the Loudness menu is relative to the selected scale, so a loudness unit of 0 corresponds to the target of the chosen measure type. For instance, if EBU R128 is selected, whose target measure is -23dB LUFS, the "0" LU (Loudness Unit) is equal to -23dB. If ATSC A/85 is chosen, whose target is -24dB, then that becomes the corresponding equivalent of the relative LU of 0.

When using the absolute scale, the Loudness meter displays the increments to reflect the chosen measure type. In absolute scale the EBU R128 meter will display -23 instead of the relative scale's 0.



The option in the Loudness panel reveals the various measure types as well as the option for absolute scale.

When working with large track counts, you can right-click on the panel and see a contextual menu that offers options for single or dual rows, as well as narrow or wide meters. You can also double click on the bus master meters on the right side to access a double row view for them.

The double height Monitoring panel

Viewer

A small viewer at the far right of the Monitoring panel allows you to view video playback; it always shows the matching video frame at the position of the playhead.

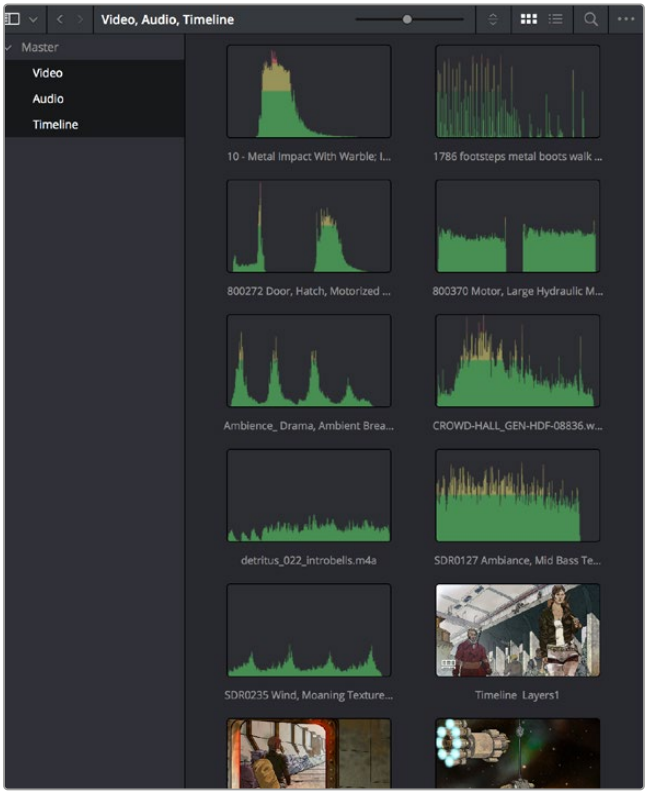
- The viewer can be resized within the monitoring panel by dragging the left or lower edge of its window.
- A button in the lower right-hand corner lets you expand the Viewer into its own floating window.
- The Fairlight page has Cinema Mode viewing (Command-F) or through the Workspace menu, Workspace > Viewer Mode > Cinema Viewer.
- You can also use the Clean Feed mode view on a separate monitor by choosing Workspace > Video Clean Feed and choosing the target monitor for dedicated video playback.
- You can choose to turn the Viewer off entirely in the Workspace > Fairlight Viewer submenu.

The Monitoring panel

The Media Pool

In the Fairlight page, the Media Pool serves as the repository of all audio clips in your project, both clips that appear within the Timeline, and clips that you've added to your project but have not yet used. When you record audio into the Timeline, the resulting clips appear in the Media Pool as well, for future use. The Media Pool appears on all DaVinci Resolve pages, and contains all of the video clips and timelines within your project.

The Bin list at the left shows a hierarchical list of folders called bins used for organizing your media, which can also used to organize your timelines. By default, the Media Pool consists of a single bin, named "Master," but you can add more bins as necessary to organize timelines and clips by right-clicking anywhere in the empty area of the Media Pool and choosing Add Bin. You can rename any bin by double-clicking on its name and typing a new one, or by right-clicking a bin's name and choosing Rename Bin. The Bin list can be hidden or shown via the button at the upper left-hand corner of the Fairlight page toolbar.



The Media Pool in Thumbnail mode showing audio clips

The browser area to the right shows the contents of the currently selected bin in the bin list. Every clip you import, every timeline you create, and every AAF, XML, EDL and other file types you can import appear here. You can create or import as many timelines as you need within a single project.

As elsewhere, the Media Pool can be displayed in either Metadata view, Thumbnail view, or List view. In List view, you can sort the contents by any one of a subset of the total metadata that's available in the Metadata Editor of the Media page. Of particular interest to audio editors are columns for Clip Name, Reel Name, different timecode streams, Audio Channels, Format, Audio Codec, Date Added, Flags, and Duration.

> For more information on using all of the features of the Media Pool, *see Chapter 18, "Adding and Organizing Media with the Media Pool."* In the following sections, some key features of the Media Pool are summarized for your convenience.

Importing Media Into the Media Pool on the Fairlight Page

While adding clips to the Media Pool in the Media page provides the most organizational flexibility and features, if you find yourself in the Fairlight (or other) pages and you need to quickly import a few clips for immediate use, you can do so in a few different ways.

Add media by dragging one or more clips from the Finder to the Fairlight page Media Pool (macOS only):

1. Select one or more clips in the Finder.
2. Drag those clips into the Media Pool of DaVinci Resolve, or to a bin in the Bin list.

   Those clips are added to the Media Pool of your project.

Use the File > Import > Media command:

1. With the Fairlight page open, choose File > Import > Media.
2. Use the Import dialog to select one or more clips to import, and click Open.

Use the Import Media command in the Fairlight page Media Pool:

1. With the Fairlight page open, right-click anywhere in the Media Pool, and choose Import Media.
2. Use the Import dialog to select one or more clips to import, and click Open.

   Those clips are added to the Media Pool of your project.

For more information on importing media using the myriad features of the Media page, see *Chapter 18, "Adding and Organizing Media with the Media Pool."*

Media Pool Preview Player

The Media Pool has a preview player at the top that provides a place to open selected source clips in the Media Pool, play them, add marks to log them, and set In and Out points in preparation for editing them into the Timeline via drag and drop. The Media Pool Preview Player effectively acts as a Source monitor for editing in the Fairlight page.

The preview player in the Media Pool

- Various viewing controls populate the title bar at the top. A dropdown menu at the upper left lets you choose a zoom level for the audio waveform that's displayed. To the right of that, a Timecode window shows you the duration of the clip or the duration that's marked with In and Out points. Next to the right, a real-time performance indicator shows you playback performance. In the center, the title of the currently selected clip is shown, with a dropdown menu to the right that shows you the most recent 10 clips you've browsed. To the far right, a Timecode field shows you the current position of the playhead (right-clicking this opens a contextual menu with options to change the timecode that's displayed, and to copy and paste timecode).
- The center of the Media Pool Preview Player shows you the waveforms in all channels of the currently selected clip, at whatever zoom level is currently selected.
- Transport controls at the bottom consist of a jog bar for scrubbing, Stop, Play, and Loop buttons, and set In and Out buttons.

Bins, Power Bins, and Smart Bins

There are actually three kinds of bins in the Media Pool, and each appears in its own section of the Bin list. The Power Bin and Smart Bin areas of the Bin list can be shown or hidden using commands in the Media Pool Options menu (...): Show Smart Bins and Show Power Bins. Here are the differences between the different kinds of bins:

- **Bins:** Simple, manually populated bins. Drag and drop anything you like into a bin, and that's where it lives, until you decide to move it to another bin. Bins may be hierarchically organized, so you can create nested bins, one inside of the other, if you like. Creating new bins is as easy as right-clicking within the bin list and choosing Add Bin from the contextual menu.
- **Power Bins:** Hidden by default. Power bins are shared among all of the projects in your current project library, making them ideal for shared title generators, graphics movies and stills, sound effects library files, music files, and other media that you want to be able to quickly and easily access from any project. You put whatever materials you want into Power Bins; it's a manual process. To create a new Power Bin, show the Power Bins area of the Bin list, then right-click within it and choose Add Bin.
- **Smart Bins:** These bins build "custom collections" of media that use metadata or analysis to automatically populate the bins dynamically, meaning that the contents will change depending on what the Smart Bin is set to focus on. For example, a sound effects Smart Bin will show only sound effects, and the bin's contents will grow or shrink depending on the number of effects files that have been identified in the project, which may change over time. Smart Bins can allow very fast and efficient organizing of project contents.

  There are several automatically created Smart Bin types available (see Preferences > User> Editing > Automatic Smart Bins).

  You can choose to have Resolve's Audio Classification analysis categorize your files (automatically creating "Collections" smart bins). Or, you can manually add metadata to your clips using the Metadata Editor, adding Scene, Shot, and Take information, keywords, comments and description text, and more to make it faster to find what you're looking for when you need it.

  You can create your own criteria for a Smart Bin. To create a new custom Smart Bin, make sure the Smart Bin area of the Bin list is showing, then right-click within it and choose Add Smart Bin. A dialog appears in which you can edit the name of that bin and the rules it uses to filter clips, then click Create Smart Bin.

NOTE: To view Smart Bins other than Keywords and Collections, you must first enable any additional Smart Bin choices in Smart Bin Preferences > User > Editing > Automatic Smart Bins.

Showing Bins in Separate Windows

If you right-click a bin in the Bin list, you can choose "Open As New Window" to open that bin into its own window. Each window is its own Media Pool, complete with its own Bin list, Power Bins and Smart Bins lists, and display controls.

This is most useful when you have two displays connected to your workstation, as you can drag these separate bins to the second display while DaVinci Resolve is in single screen mode. If you hide the Bin list, not only do you get more room for clips, but you also prevent accidentally switching bins if you really want to only view a particular bin's contents in that window. You can have as many additional Bin windows open as you care to, in addition to the main Media Pool that's docked in the primary window interface.

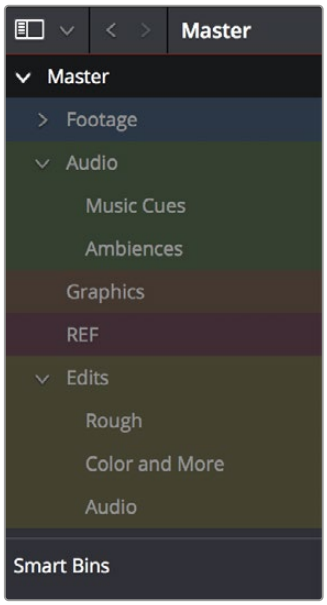
Filtering Bins Using Color Tags

If you're working on a project that has a lot of bins, you can apply color tags to identify particular bins with one of eight colors by right-clicking any bin and choosing the color you want from the Color Tag submenu.

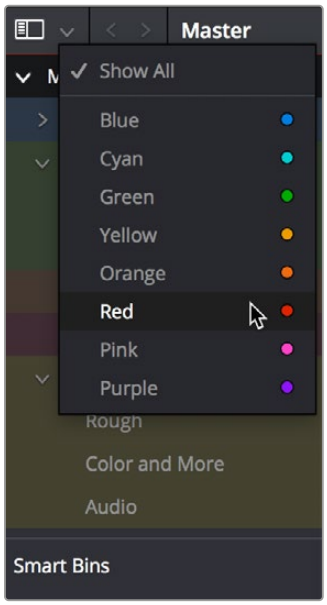
For example, you can identify the bins that have clips you're using most frequently with a red tag. A bin's color tag then appears as a colored background behind that bin's name.

Once you've tagged one or more Media Pool bins, you can use the Color Tag Filter dropdown menu (the dropdown control to the right of the Bin List button) to filter out all but a single color of bin.

To go back to seeing all available bins, choose Show All from the Color Tag Filter dropdown.



Using color tags to identify bins



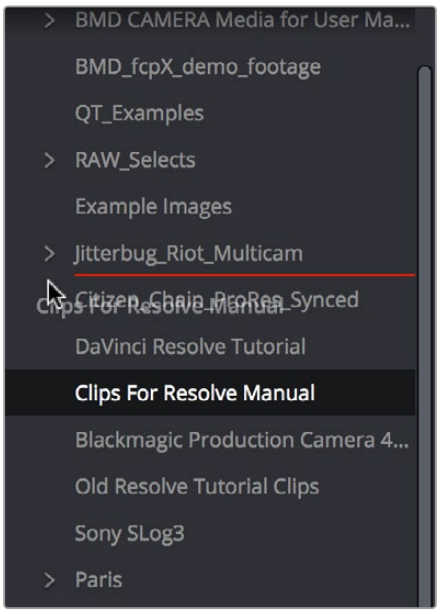
Using Color Tag filtering to isolate the red bins

Sorting the Bin List

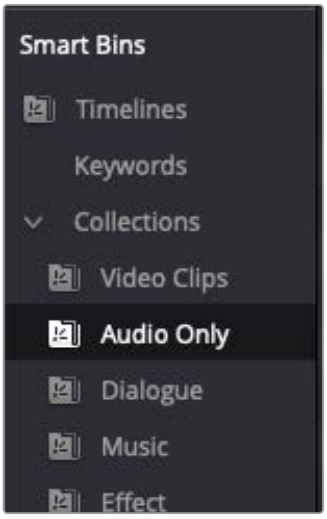
The Bin list (and Smart Bin list) of the Media Pool can be sorted by Bin Name, Date Created, Date Modified, in either ascending or descending order. Simply right-click anywhere within the Bin list and choose the options you want from the Sort by submenu of the contextual menu.

You can also choose User Sort from the same contextual menu, which lets you manually drag all bins in the Bin list to be in whatever order you like. As you drag bins in this mode, a red line indicates the new position that bin will occupy when dropped.

If you use User Sort in the Bin list to rearrange your bins manually, you can switch back and forth between any of the other sorting methods (Name, Date Created, Date Modified) and User Sort. Your manual User Sort order will be remembered, making it easy to use whatever method of bin sorting is most useful at the time, without losing your customized bin organization.



Dragging a bin to a new position in the Bin list in User Sort mode



The Audio Only Smart Bin

Filtering Clips With Audio in the Fairlight Page

The Media Pool on the Cut, Edit, Color, Fusion and Fairlight pages can show Audio Only clips using the Collections smart bin labeled “Audio Only” found in the Collections are of Smart Bins. This makes it easy for you to find audio clips that you’re looking for, which may be hidden along with lots of video clips in the same bin.

The Media Pool filter options in the option menu

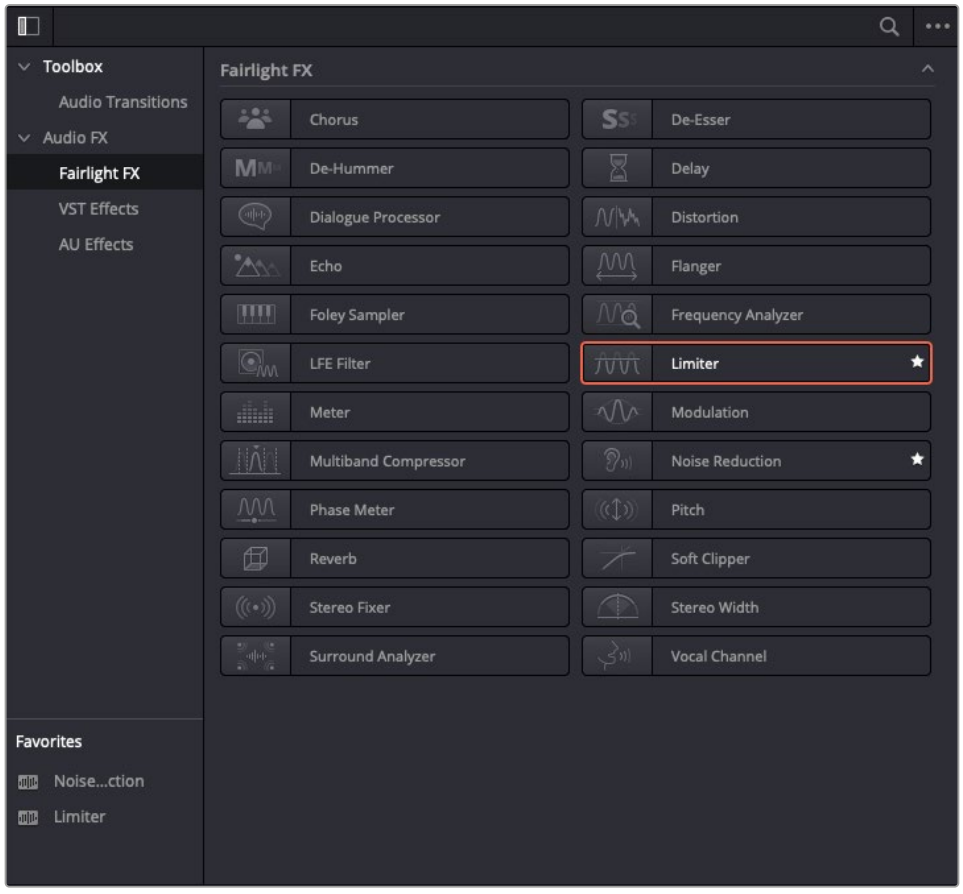
If you’d like to work with some additional options, the Media Pool in the Fairlight page also has the ability to filter out audio-only clips, or video clips with audio, in the currently selected bin. To use this feature, click the Option menu of the Media Pool and choose Show All Clips, Show Audio Only Clips, or Show Clips With Audio, Show Audio Waveforms, and Show Non-Rectified Audio Waveforms.

Effects Library

The Effects Library on the Fairlight page displays both the built-in Fairlight FX audio plugins that accompany DaVinci Resolve on macOS, Windows, and Linux, as well as whatever Audio FX are available on your workstation.

- Fairlight FX are built-in audio processing effects that are fully cross-platform on all platforms DaVinci Resolve supports.
- On macOS and Windows, DaVinci Resolve supports the use of third-party VST audio plugins.
- On macOS, DaVinci Resolve supports Audio Unit (AU) audio plugins.

Once you install third-party effects on your workstation, they appear in this panel of the Effects Library alongside the Fairlight FX that are always available. Audio plugins let you apply effects to audio clips or as a real time process on an entire audio track (affecting all clips on that track), to add basic dynamics or tonal processing compression, limiting or EQ, noise reduction, or creative spatial effects like delay or reverb.



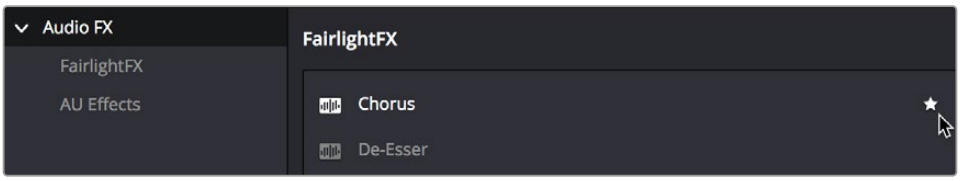
The Effects Library

Similar to the Media Pool, the Effects Library's Bin list can be opened or closed using a button at the top left.

Effects Library Favorites

To save an effect as a Favorite:

- Hover over the far right of any effect to see a star
- Click on the star to add the effect to the Favorites effects list.
- Favorites appear in a separate area on the lower left next to the Effects Library Bin list.



Stars indicate a flagged favorite effect, all favorites are currently filtered

NOTE: Items that are set as Favorites in the Effects Library list will also appear at the top of the Mixer's Effects dropdown menu effects list.

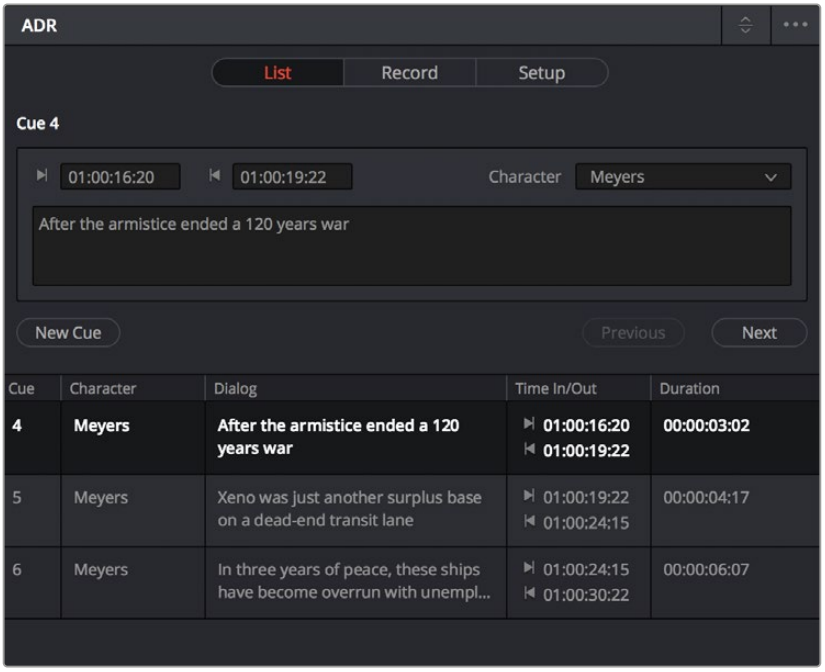
ADR

The Fairlight page of DaVinci Resolve has a sophisticated, yet intuitive, interface for doing "ADR" (Automated Dialog Replacement). Comprehensive cue list management, industry-standard audio beeps and visual cues, sophisticated take management with star ratings and layered take organization help you manage your work while getting the best parts of each performance.

When open, the ADR interface consists of three panels to the left of the Timeline: a List panel, a Record panel, and a Setup panel.

The List Panel

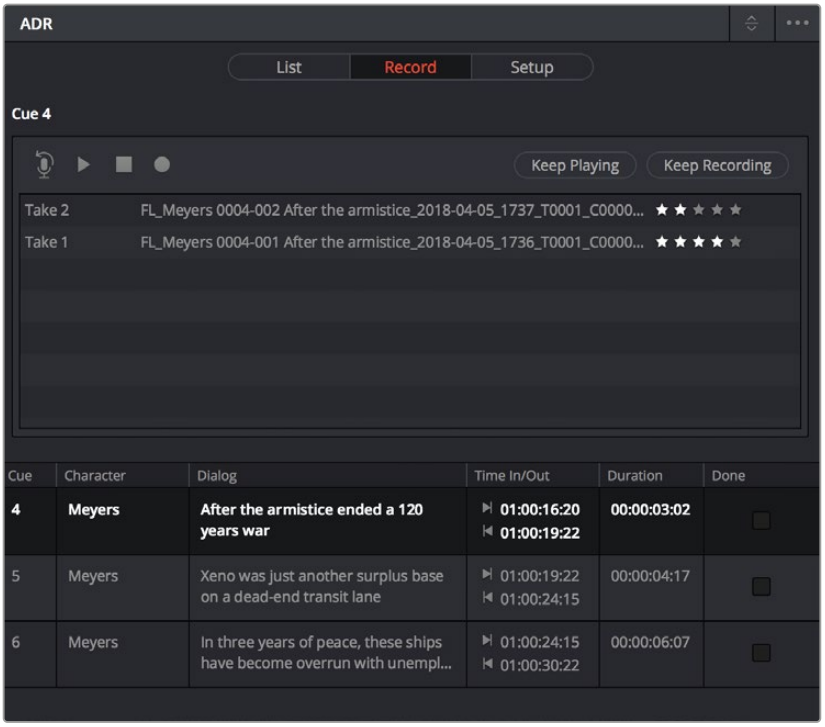
This is where you create a list of cues you need to re-record, either from within the Fairlight page, or imported from a .csv file that someone provides you. It presents controls for adding, editing, importing, and exporting cues that you want to record.



The Setup panel of the ADR interface

The Record Panel

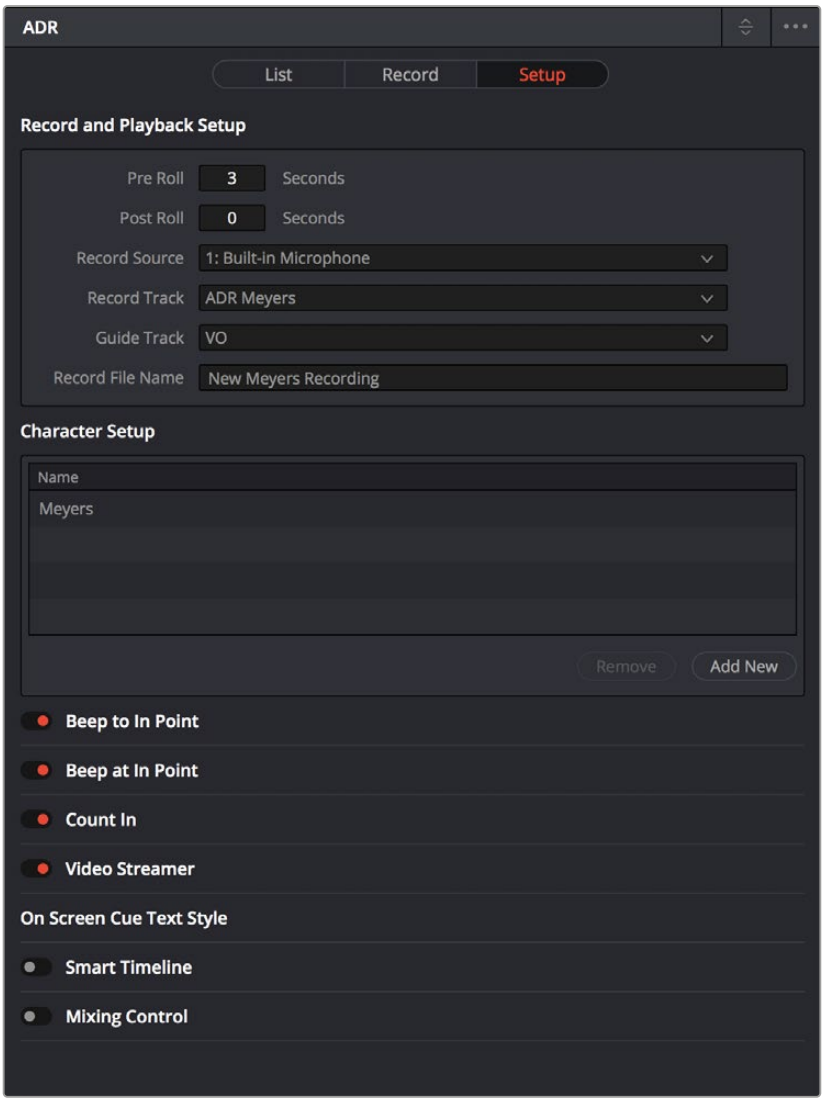
This is where you actually run the ADR recording session you've set up, using the dialog cues you've put into the Cue list. It presents controls for displaying and selecting which cues to record, previewing and initiating recording, and adding metadata to rate the different takes you've recorded and to keep track of which cues have been completed.



The Record panel of the ADR Interface

The Setup Panel

The Setup panel is where you configure your ADR session. Choose your audio input, your record track and what tracks to monitor. Then access beeps, video streamers and onscreen text that the actors will see on the video output display to help them keep their performance in sync.



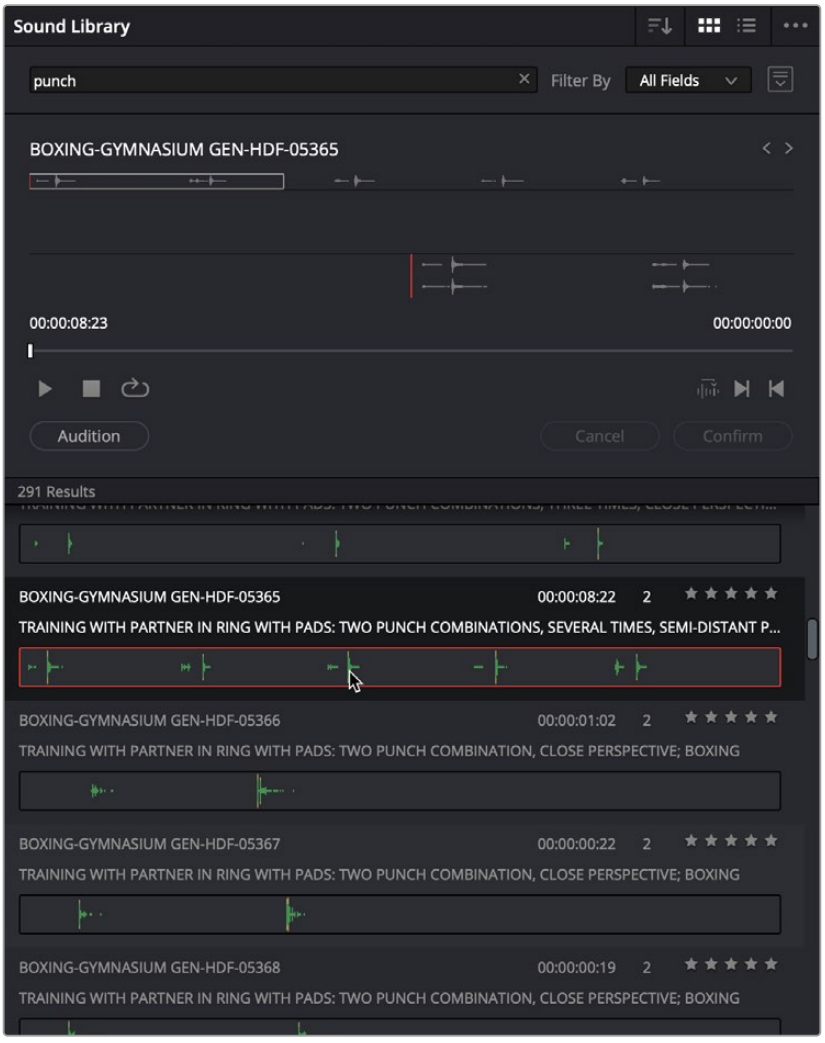
The Setup panel of the ADR interface

For more information on using the ADR panel, *see Chapter 171, "ADR (Automated Dialog Replacement)."*

Sound Library Browser

A Sound Library panel is available from the Interface toolbar for browsing sound effects libraries that you have available to you, on your system or on network storage you may be connected to (for example, a SAN). It includes the capability of scanning specified file paths to catalog available sound files and their metadata, storing this data within the currently selected project library (or another project library that you select) to use when searching for the perfect sound effect within your library. Once you've cataloged your sound effects collection, it's easy to search for sounds, preview what's been found in the list, and edit the one you like best into the Timeline.

TIP: You can download the Fairlight sound library, a royalty-free collection of over 500 professionally recorded foley sounds that you can use in your own projects, which are directly downloadable from the Sound Library panel. The Fairlight sound library features everything from atmospheric ambient sounds to foley sounds such as foot steps, hits, effects, and more. This free sound library is designed to work with the Fairlight FX Foley Sampler plugin, which lets you use a MIDI keyboard to trigger sounds so they can be recorded at precisely the right time in your program.



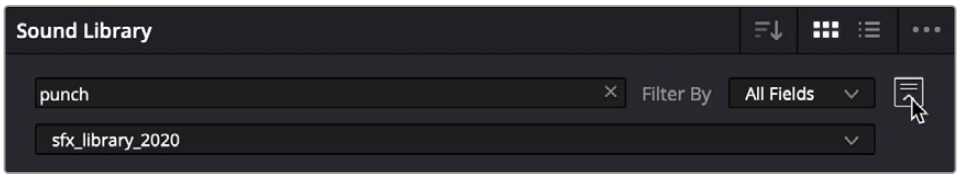
The Sound Library panel

Library Controls

Clicking the Library button (to the right of the Search field) reveals a menu that lets you choose which project library to use for searching (and cataloging) sound effects collections. Each network project library can have a different catalog.

NOTE: The Sound Library results pane will be empty until a search is made.

The Sound Library is capable of using the Mapped Mount option in the Media Storage panel of the Preferences, in order to access sound effects located on remote volumes using other operating systems.



Choosing a library to search

To catalog all audio files within a given file path for searching using the Sound Library:

1. Using the Project Manager, create an empty network project library to store the sound effects catalog.
2. Open a project, open the Edit or Fairlight pages, then open the Sound Library.
3. (Optional) Click the Library button (to the right of the Search field), and select the project library you created using the dropdown menu that appears. The current project library is selected by default. If you're working within a local project library instead, the top compatible project library in the list will be the default.
4. Do one of the following:
    a) If you've not yet connected a library of sound effects, an Add Library button appears in the center of the Sound Library. Click this button, and from the file dialog that appears, select the top-most directory of a file path that contains sound effects; if you've selected a directory with subdirectories inside, each subdirectory will be examined for content.
    b) If you're adding more sound effects to an existing library, then click the Option menu and choose Add Library. From the file dialog that appears, select the top-most directory of a file path that contains sound effects; if you've selected a directory with subdirectories inside, each subdirectory will be examined for content.
5. Click Open.

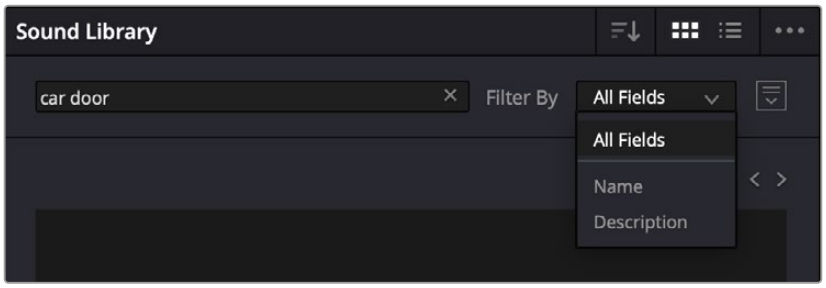
A progress bar will show you how long the operation will take. When you're finished, a dialog will appear letting you know how many clips were added to the current library.

Display Controls and the Search Field

The Sound Library title bar has controls for sorting the sound effects list, showing it in List or Icon view, and an Option menu with various other settings and commands.

Display controls let you choose how the contents of the Sound Effects list are viewed

Underneath, a text field lets you enter search terms, while a dropdown menu to the right lets you choose whether to search the current project library for sound effects by name, description metadata, or all.



The Search field and Filter By menu

To search for a specific sound effect and edit it into the Timeline:

- Type a search term into the Search field. The case of search terms is ignored, except for boolean operators.

To help you to eliminate false positives, the search field supports different kinds of searches, such as literal searches, and/or/not boolean searches, wildcard searches, and ranges of characters.

NOTE: If you want to perform Boolean searches, the Boolean operators must be typed in all upper caps, such as “AND,” “OR” and “NOT.” If lower case is used, “and,” “or” and “not” will be treated as search terms but as regular words.

Or/And/Not Searches

Simply typing words separated by a space is treated as a series of OR searches for each word independently of one another, either literally or as part of another word. For example, if you type either of the following:

```
car door
car OR door
```

both yield the same results. Every sound effect in your library containing either the letters “car” or “door” (or both) will appear, whether these letters appear independently, or within other words. Results will include files such as “CarExDoorClose,” “Doormouse_Squeak,” “Carburetor dropped on cement,” and “Carpet Shake.”

Using AND (it must be upper caps) lets you specify multiple criteria for a search, when each file that's returned should contain every word you type somewhere within, in any order. For example, if you type:

```
car AND door
```

every sound effect in your library containing both the strings "car" and "door" will appear, even if these words appear either singly, in combination, or within other words, such as "NewCarDoorSlam" and "Carpet_Footsteps_Indoors," and "GarageDoorHitsCar."

Using NOT lets you omit sound effects that have a particular word. For example, if you type:

```
car NOT door
```

only sound effects with "car" will appear, and all sound effects with "door" will be omitted.

Literal Searches

Using quotations specifies a literal search for only the specified term, separated from other text by a space. For example, if you type:

```
"cat"
```

every sound effect in your library with the standalone word "cat" appears. Sound effects with "cats" and "caterpillar" will be omitted. Results will include "Space cat drone" or "Cat meowing."

Wildcard and Range Searches

The * (asterisk) specifies a wildcard search of any number of characters. Adding an * between two search terms identifies any sound effect with the two search terms connected by any number or combination of characters with no spaces (even no characters). For example, if you type:

```
close*door
```

results include "Door-Wood Cheap-Wooden-Closet-Door-Kick-In-Flimsy-Rattle," "ElevatorCabinCloseDoor," and "LatchSwingCloseSqueakDoorSecur." If you instead type:

```
door*close
```

results include "DoorHvyMetalCloseSlam," "DoorLidWoodenChestCloseAntique," and "ElevatorDoorCloseSlam." If instead you type:

```
c*r
```

results include "lectrohummin," "KiaShumaEXTBootCloseTrunkaka," and "Ambience with Piana, Louder."

The ? (question mark) specifies wildcard search specifying only a single character. The number of question marks you type specifies how many characters of wildcard searching you want to perform. For example, if you type:

```
door?close
```

you may get no results at all, unless you have a sound effect named "door-close." However, if you type:

```
door????close
```

results include “DoorWoodClose” since the word wood is four letters, matching the number of wildcard letters you’ve specified.

TIP: Typing “***” will show all of the files in your Sound Library

Preview and Audition Controls

Selecting an item in the Sound Effect list loads it into the preview player where you can play it or audition it in your timeline using the controls underneath the search field.

- **Clip name:** The name of the current clip you’ve selected.
- **Next/Previous buttons:** Two buttons let you select the next or previous sound effect clip in the Sound Effect list.
- **Duration display:** Shows the duration of the current clip, or of the section of the clip marked with In and Out points.
- **Playhead timecode display:** The playhead’s current position.
- **Waveform overview display:** The waveform of the entire sound effect appears here, providing a zoomed out view of the selected clip. All channels are summed together in this display.
- **Zoomed in waveform display:** A zoomed-in section of the selected clip that lets you see more waveform detail for setting In, Out, and Sync points.
- **Jog bar:** Lets you navigate through or scrub around the clip.
- **Transport controls:** Play, stop and loop buttons let you control playback, although you can also use the space bar and JKL controls. Right-click the Stop button to switch it into “Stop and Go to Last Position” mode.
- **Marking controls:** The Sync Point button lets you mark a specific frame on the sound effect that you want to sync to the Timeline’s current playhead position when you use the Audition controls. The In and Out buttons let you mark which portions of the sound effect clip you want to edit into the Timeline.
- **Audition controls:** The Audition button puts you into Audition mode, where the currently selected sound effect clip is automatically placed at the position of the playhead in the currently selected Timeline track. You can then move over to the timeline and listen to the clip in your mix. Cancel and Confirm buttons let you choose whether you want to remove the clip from the Timeline and try again with another clip, or leave the sound effect clip in.

To audition clips you’ve selected in the Sound Library in the Timeline:

1. Select a sound effect clip you’ve found from the list that you want to audition in the Timeline.
2. (Optional) In the Sound Library, use the scrubber bar to move the playhead to the part of the sound effect that you want to sync to, and click the Sync Point button to place a sync mark on that clip.

   For example, if you’re syncing the sound effect of a car door closing, you might sync the first frame of the door fully closed to the peak of the “slam” sound effect, rather than any door squeaking earlier in the sound effect.
3. (Optional) Set In and Out points to define the range of the sound effect you want to potentially use.
4. Select a track you want to preview the sound effect in by clicking its track header or Mixer channel strip.
5. Position the playhead at the place in the Timeline you want to place your clip.

6 Click the Audition button in the Sound Library. That clip now appears, temporarily, in the Timeline, and you can play through that section of the Timeline to see how you like the sound effect in context with the rest of the mix.

7 If you like the sound effect, click Confirm to keep it in the Timeline. If you don't, click Cancel, and it will disappear from the Timeline.

NOTE: In order Use the Audition function, a track has to be selected first.

Additionally, if you select another sound effect after auditioning, without first confirming the prior sound, the Audition process is cancelled, and the prior sound is removed from the timeline.

Sound Effect List

All sound effect clips that match the current search criteria appear in this scrollable list. Double-clicking anywhere on an item of this list plays that sound effect in its entirety.

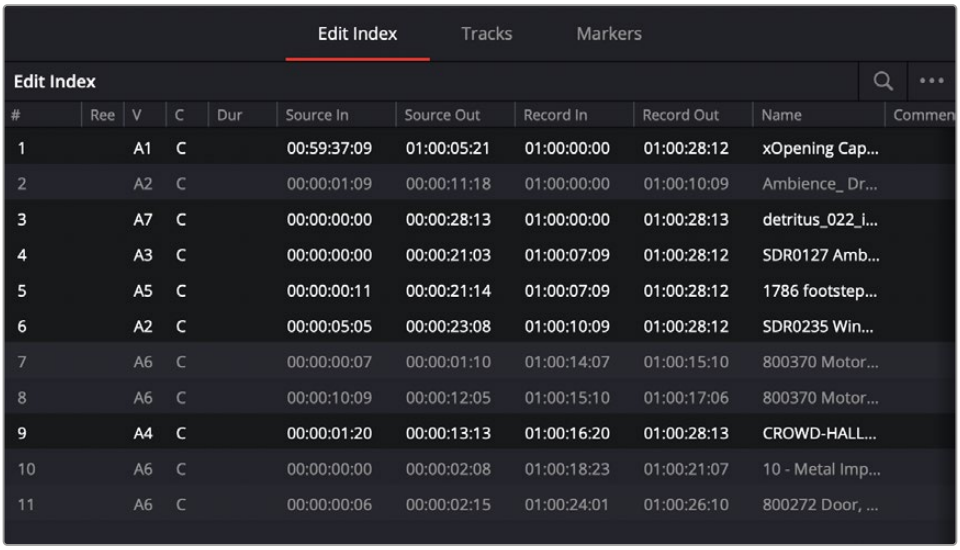
- **Clip Name:** The name of that sound effect file in the storage system.
- **Description:** Any metadata that's embedded within the files of professionally created sound effect libraries appears here.
- **Duration:** The duration of that sound effect file.
- **Audio Channel:** The number of channels in that sound effect file.
- **Star rating:** A clickable control you can use to rate sound effects within DaVinci Resolve. Star rating information is not saved outside of DaVinci Resolve.
- **Waveform:** The overall waveform of the entire sound effect library is stretched or compressed within the available width of the Sound Library, regardless of the actual duration of each clip.

Index

The Index provides a handy interface for listing all of the clips in the current edit, all the tracks in the current Timeline, and all the markers in the current Timeline. Using these lists, multiple items can be selected, tracks can be managed, and marker notes can be consulted with ease. Each of these three categories of information is displayed in separate panels: the Edit Index, Tracks, and Markers.

Edit Index

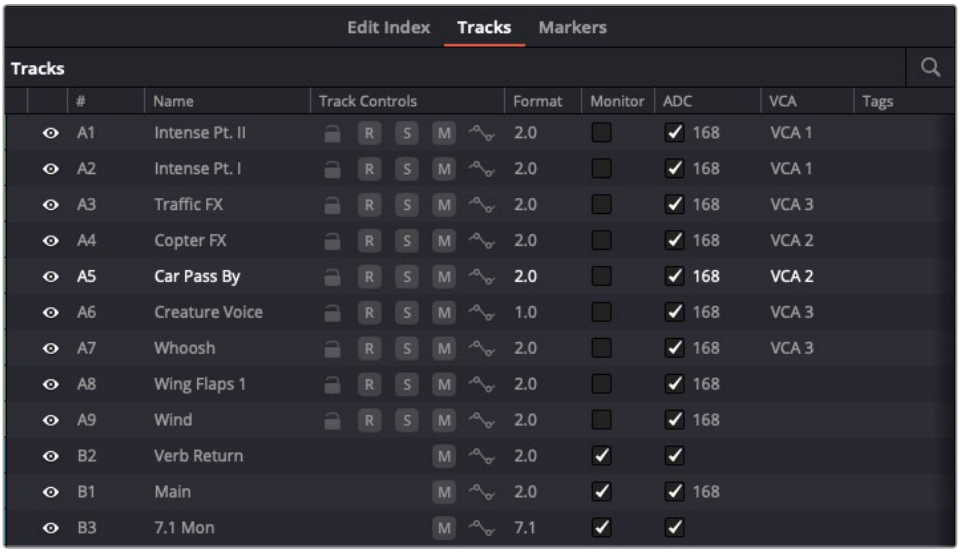
Displays the Edit Index as seen in the Edit page. Each audio clip in the currently open Timeline corresponds to a row in the Edit Index, with columns for video track, Source In and Out, Record In and Out, Name, and other descriptive metadata. All selected clips (including clips that are automatically selected because they intersect the playhead) are selected in the Edit Index. The Option menu lets you filter the Edit Index by various criteria, for example showing only clips with a particular color of flag, marker, or color, only clips with speed effects, only clips with audio filters, or compound audio clips.



The Tracks panel shows a row of information for each of the tracks in the Timeline

Tracks

Every track in the currently open Timeline corresponds to a row of controls and information in this panel. From left to right, each track has a color control, a visibility control, a number, a name, track controls, a format, ADC, Tags, and, if a VCA is used, the number of that VCA group. These controls can be used to hide or show tracks, color code them, rename them, turn track controls on singly or by dragging over several at a time, change their format, add to (or remove them from) the audio monitor list, and rearrange them (by dragging one or more rows up and down this list) and toggle the automatic delay compensation (ADC) on/off (on by default).



The Tracks panel shows a row of information for each of the tracks in the Timeline.

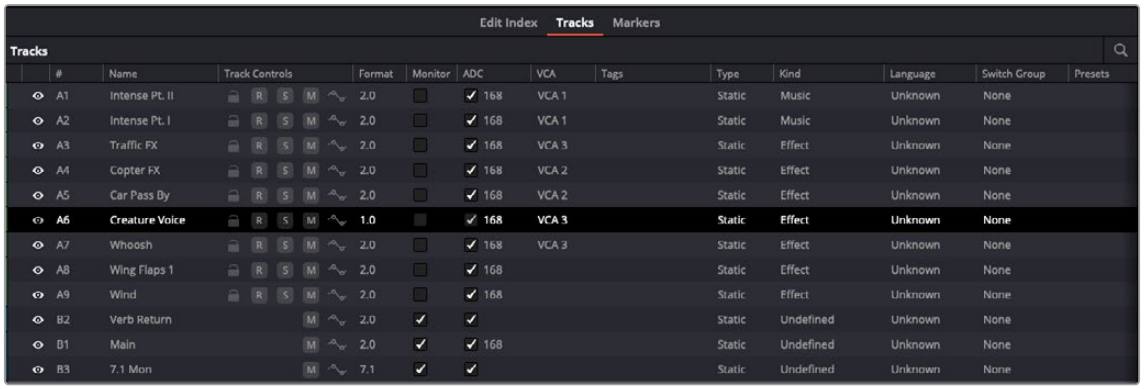
NOTE: The ADC column (automatic delay compensation) has a check box allowing the enabling of ADC on a track-by-track basis.

Audio Monitor Checkbox

A monitor checkbox appears for each bus or track in the Tracks list. When checked, that track or bus will appear in the Audio Monitoring dropdown menu as a choice for monitoring. All busses are checked on by default, and will appear in the list unless unchecked here.

MPEG-H Options in the Tracks Panel

If you have MPEG-H enabled for immersive audio authoring in the preference pane of Video and Audio I/O, additional columns appear in this panel.



When MPEG-H is enabled, the Tracks panel shows additional columns of metadata information for defining each track in the Timeline.

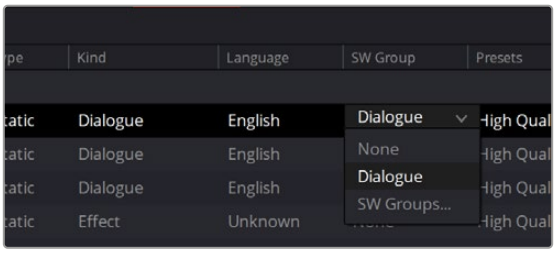
These columns include:

- **Track Type:** Allows definition of either a static component or a dynamic object. When dynamic is selected, the dynamic track-level pan automation from that track is also exported. Only a track can be set to dynamic.
- **Kind:** A content type label, such as Mixed content, Music, Dialogue, Effect, etc. When Kind is defined for a bus (rather than the default state of Undefined), that bus is automatically bounced during the export process.
- **Language:** The content-specific language for that track.

  Switch Group: Allows the track to be assigned to a user-defined switch group. A switch group allows the track to be grouped together with other tracks in the final content, forming a selectable item when rendered. For example, a switch group of dialogue, containing an English and a Chinese language track, could allow the user to select between these languages on playback. In order to define a switch group, click that track's cell in the Switch Group column, and choose "Sw Groups..." to open the Switch Groups Manager window, which lets you create new switch groups.

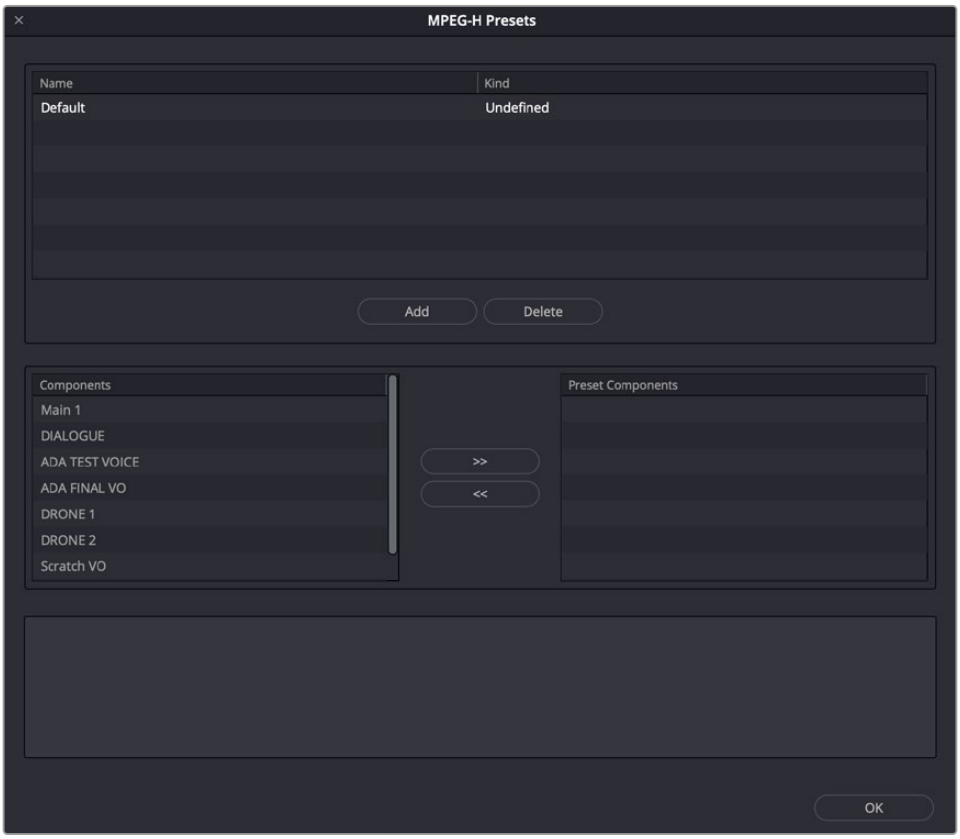
The Switch Group Manager

Once one or more groups has been created, they're available for selection in the dropdown menu of any cell in the SW Groups column. This lets you quickly make a variety of custom assignments.



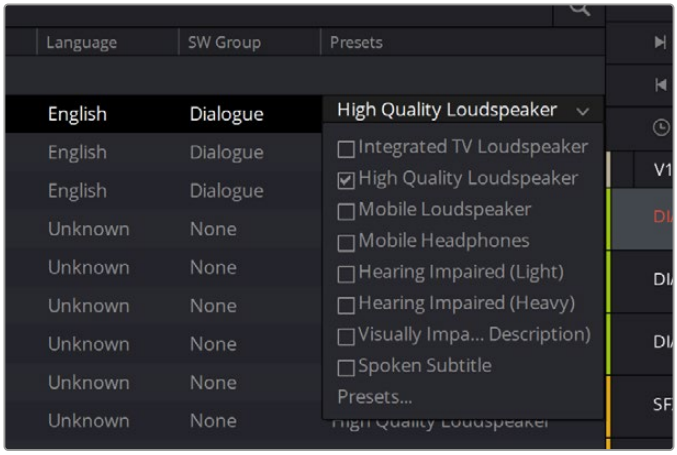
The dropdown in the SW Group column

- **Presets:** Allows a track to be assigned to a user-defined preset. For example, a Bed Mix and Language switch group could form one preset, while the same tracks and a spoken subtitle could form another. In order to define a Preset, click that track's cell in the Presets column, and choose "Presets..." to open the Preset Manager window, which lets you create new Presets.



The Preset Group Manager

Once one or more presets has been created, they're available for enabling in the dropdown menu of any cell in the SW Groups column. Any track can be added to multiple presets, so the Presets dropdown contains one checkbox per preset so you can make multiple assignments.

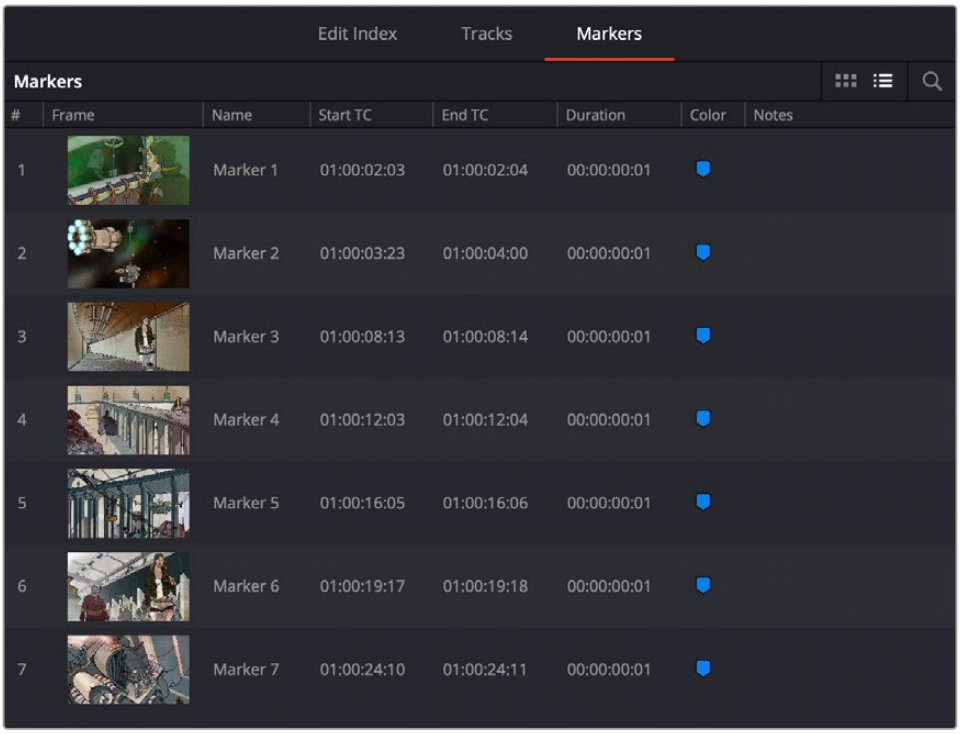


The dropdown in the Presets column

Once configured, the metadata from these presets form how the content is exported in the final deliverable, so there will be a set of presets that contain all configured components and switch groups.

Markers

The markers panel can be displayed in either thumbnail or list mode. In thumbnails mode, each marker in your timeline corresponds to a thumbnail displaying the timecode of its location underneath it, and the color of the marker to the left of the timecode location. In list view, each marker displays a row with the following information; marker number, frame (showing a thumbnail), marker name, start timecode, end timecode, duration, marker color, and notes.



The Markers panel shows a row of information for each of the markers in the Timeline.

Inspector

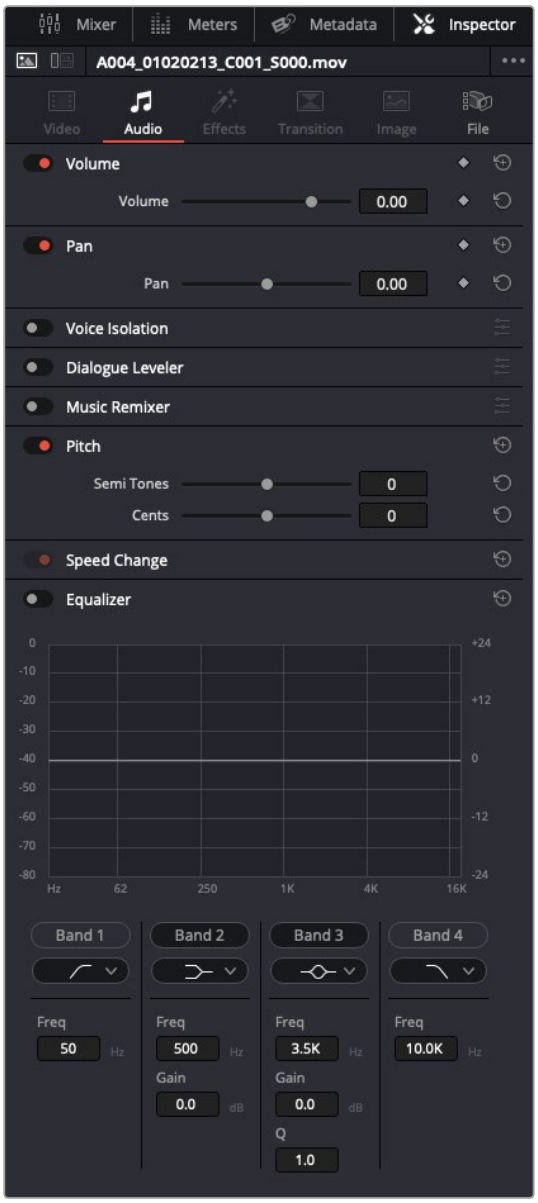
The Inspector's Audio, Effects, and File panels on the Fairlight page offer features for working with selected tracks, buses, and clips on the Audio Timeline.

TIP: You can make "granular" adjustments to virtual sliders by holding down the Option or Shift key while clicking in and dragging left or right within the numerical value field.

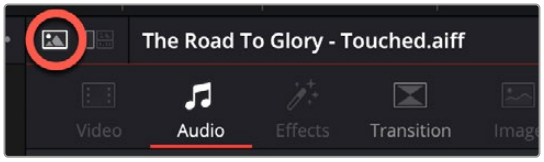
The Audio Tab

The Audio tab lets you adjust the volume level of a selected track and apply and adjust Track FX.

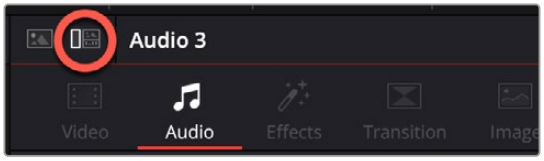
When working with audio clips on the Audio Timeline or Media Pool, you can adjust the volume level and pan setting of a selected clip, apply and adjust a selection of Fairlight FX and EQ, and raise or lower the clip's pitch.



Fairlight page - Inspector - Audio tab



The Audio Inspector in Clip mode (circled)



The Audio Inspector in Track mode (circled)

The Effects Tab

Audio Effects added to a track or bus via the Effects section of its Mixer channel strip or to a Timeline clip from the Effects Library will appear in this panel.

The File Tab

This panel lets you view and edit the metadata and configuration of selected Timeline or Media Pool clips.

> For details on the Inspector for the Fairlight page, *see Chapter 173, "The Fairlight Inspector."*

Clip Mode vs. Track Mode

The Inspector includes a Clip Mode and Track Mode button to eliminate confusion about whether your parameter property changes in the Audio tab are applied to an audio clip or a track.

- Selecting an audio clip in the Media Pool or on the Timeline activates the Clip Mode button, and the clip name appears at the top of the Inspector, to the right of the Track Mode button.
- Clicking the Track Mode button while a Timeline clip is selected causes subsequent changes in the Audio tab to apply to the corresponding Mixer channel. The clip name at the top of the Inspector will switch to the track name.

> For details on the Fairlight Page Inspector, *see Chapter 173, "The Fairlight Inspector."*

Test Tone Settings for Generating Tone, Noise, and Beeps

The Fairlight page has a general purpose oscillator, the settings of which you can customize by choosing Fairlight > Test Tones Settings. This opens the Test Tones Settings window that you can configure to generate tones, noise, or beeps using five sets of controls:

- **Enable/Disable Test Tones toggle:** Lets you turn the Oscillator on or off system-wide.
- **Frequency control:** Sets a custom frequency of oscillating tone, from 20 Hz to 15kHz. Defaults to 1kHz.
- **Frequency buttons:** Lets you quickly select 100, 440, 1K, or 2K preset tones, or a continuous rising sweep of frequencies from 20 Hz to 15kHz.
- **Noise type buttons:** Two buttons let you choose from White noise or Pink noise.
- **Level dial:** Sets the output level for the tone or noise, from –50dB to +10dB. Defaults to –15 dB.

You can set up the Oscillator to output whatever kind of tone or noise you require, and then patch it to tracks for recording tones, or patch it to audio outputs for calibrating speakers. If you use the beep options of the ADR panel, those are performed via the Oscillator.

To play the Test Tone out of your speakers:

1. Choose Fairlight > Patch Input/Output to open the Patch Input/Output window.
2. Choose System Generator from the Source dropdown menu, and choose Audio Outputs from the Destination dropdown menu.
3. At the left, click the button of what you want to output, Osc (Oscillator) or Noise.
4. At the right, click the connected audio outputs that you want to patch to, and click Patch. Tone or noise should immediately start playing out of your configured speakers. Depending on any particular track's I/O settings, if you have patched the Osc through a track you may need to either Arm the track by pressing the R (record) button, or in the channel's Path Settings press the Thru button, to have the signal pass through for output monitoring.
5. To stop, select one of the patched buttons, and click Un-Patch.

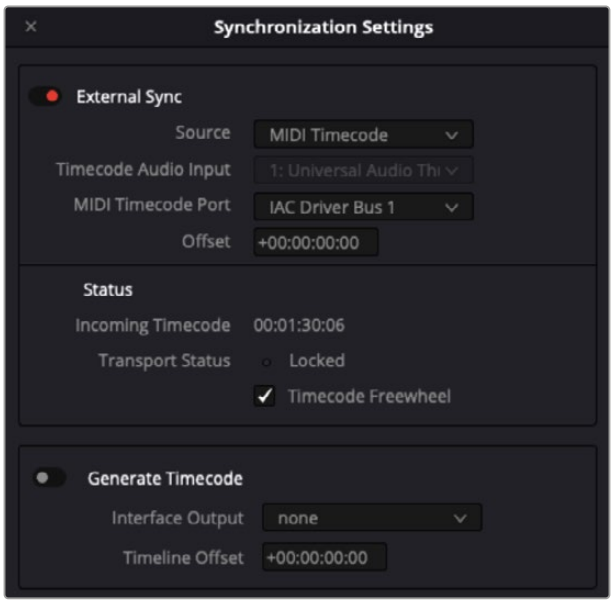
To record a tone or noise from the Oscillator to an audio track:

1. Choose Fairlight > Patch Input/Output to open the Patch Input/Output window.
2. Choose System Generator from the Source dropdown menu, and choose Track Input from the Destination dropdown menu.
3. At the left, click the button of what you want to output, Osc (Oscillator) or Noise.
4. At the right, click the connected audio outputs that you want to patch to, and click Patch. Close the Patch Input/Output window.
5. Click the Arm Record (R) button in the track header of the track you patched the Oscillator to. If your Main is properly patched to your outputs, you should hear the tone or noise, and that track's audio meter should reflect the level being output by the Oscillator.
6. Click the Record button of the transport controls to initiate recording of that tone to the patched track. Click the Stop button or press the Spacebar to halt recording when you're done.

Working with Timecode

Fairlight includes synchronization options that let you configure DaVinci Resolve to either chase and synch to an external device or another application or generate and transmit timecode as an audio signal so an external device can follow your Timeline.

You can access these settings by clicking the Fairlight menu and choosing Synchronization Settings.



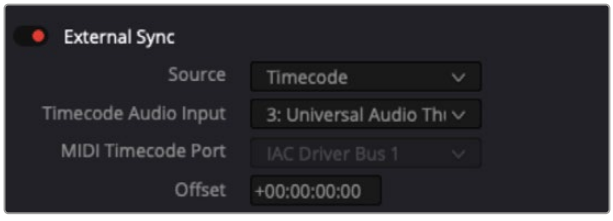
Fairlight Synchronization settings

LTC and MTC Chase Sync

LTC Synchronization

If, for example, you want to configure Fairlight to chase and sync to either an external device or computer system:

1. Enable External Sync.
2. Choose the Timecode option from the Source dropdown.
3. Select an appropriate audio input on your audio interface from the Timecode Audio Input dropdown.
4. If needed, set your SMPTE offset. Otherwise, leave it set to +00:00:00:00.
5. Begin playback on the external device. Your mix in Fairlight will play back in sync with the external device.

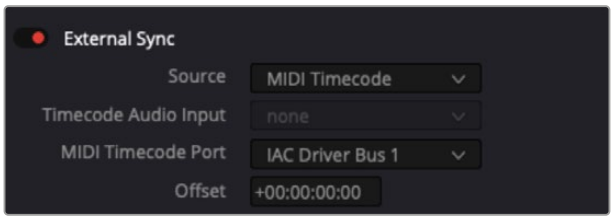


External Sync via LTC enabled

MTC Synchronization

To Configure Fairlight to chase and sync to either an app on your computer, such as a DAW, or an external device that can transmit MIDI timecode:

1. Enable External Sync.
2. Choose the MIDI Timecode option from the Source dropdown.
3. Select the appropriate MIDI port from the MIDI Timecode Port menu. For example, if you want to sync DaVinci Resolve to a DAW on your computer, choose IAC Driver Bus 1.
4. If needed, set your SMPTE offset. Otherwise, leave it set to +00:00:00:00.
5. Begin playback on the external device or DAW, and the audio from Fairlight will play back in time.

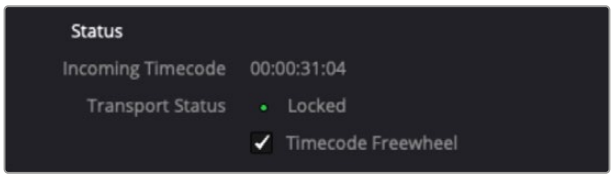


External Sync via MTC enabled

Status

This section of the Synchronized Settings dialog provides real-time information about the current synchronization status during playback.

- **Incoming Timecode:** During playback, this field continually updates with the current timecode transmitted to DaVinci Resolve.
- **Transport Status:** This indicator turns green to reflect stable synchronization during playback.
- **Timecode Freewheel:** When this checkbox is filled in, Fairlight will generate its own timecode for a short time in case of issues with the incoming timecode. This process maintains stable and uninterrupted synchronization.

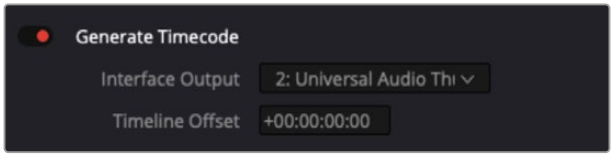


Sync Status pane

Generating Timecode

To generate and transmit timecode as an audio signal from your audio interface to an external device or application:

1. Switch on Generate Timecode.
2. Select the audio interface output from the Interface Output dropdown you want to transmit the timecode audio through.
3. Begin playback of your mix in Fairlight. DaVinci Resolve will continue sending the timecode audio signal to the destination until you click the Stop button.



Generate Timecode enabled

TIP: If you're using a Fairlight SX36 audio interface, the signal can be used to synchronize another DaVinci Resolve system or any system that can use timecode audio as a reference.

Pro Tools AAF Import

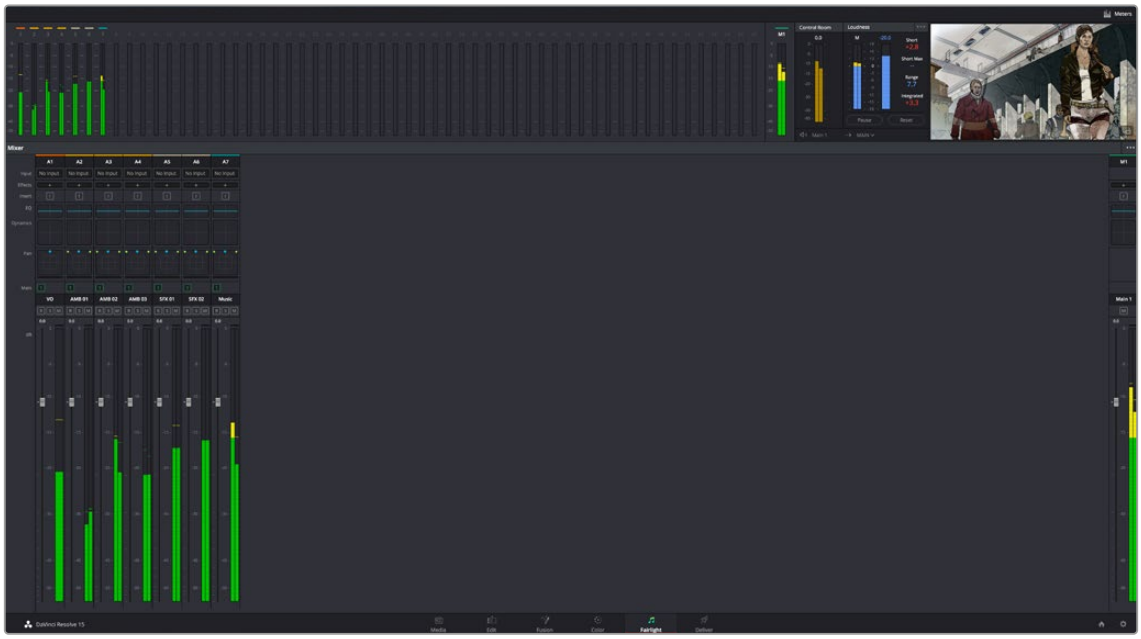
DaVinci Resolve can import AAF projects and media from Pro Tools, enabling you to move an audio project from a Pro Tools workstation to a Fairlight workstation. AAF import supports the import of embedded audio and track automation. To do so choose File > Import Timeline > Import AAF/EDL/XML.

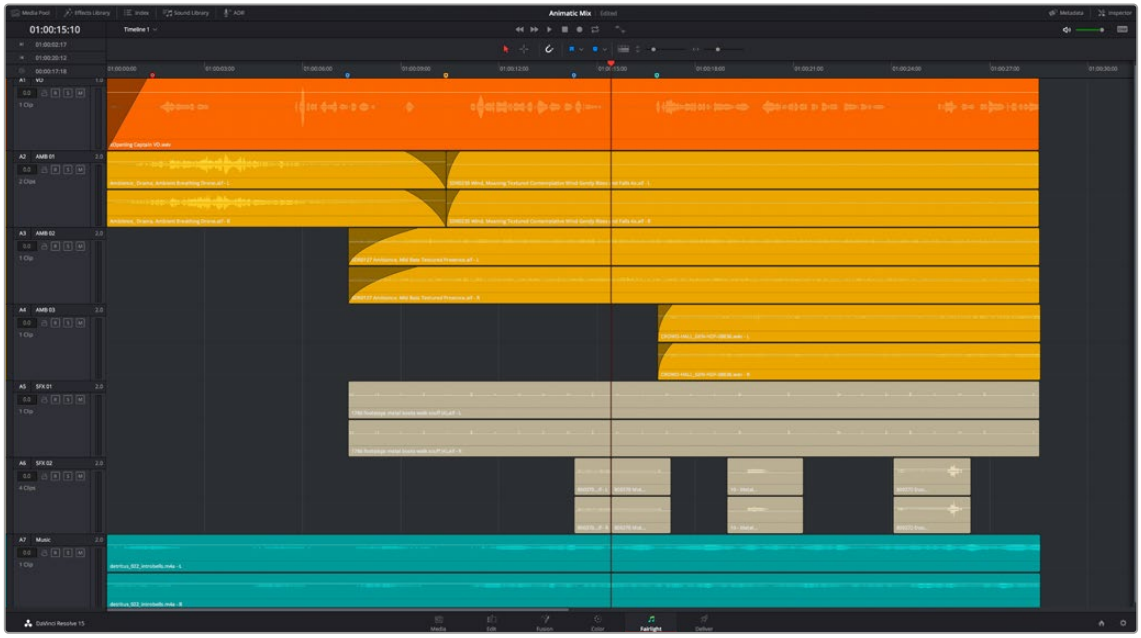
Dual Monitor Layout

The Audio page has a dual monitor layout that provides maximum space for the mixer and audio meters on one screen and a full-screen timeline on the other.

To enter dual screen mode:

- Choose Workspace > Dual Screen > On.





The Fairlight page in dual screen mode

To switch which UI elements appear on which monitors:

- Choose Workspace > Primary Display > Display 1 or Display 2, which reverses the contents of both monitors in dual screen mode.

Customizing the Fairlight Page

The default layout is quite efficient for a number of tasks on most displays. You can always return to the default layout by choosing Workspace > Reset UI Layout. However, the Fairlight page can be customized to create more room for specific areas of the interface to accommodate different tasks.

To resize any area of the Fairlight page:

- Drag the vertical or horizontal border between any two panels to enlarge one and shrink the other.

To resize the height of individual audio tracks:

- Move the pointer to the bottom border of any audio track header, and when it becomes a resize cursor, drag that border up or down to resize that track. Each track can have an independent size when you do this.

To resize any column of the Index:

- Move your pointer over the divider between any two columns and drag when the horizontal resize cursor appears.

To rearrange Index columns:

- Drag the header of any column to the left and right to move that column.

NOTE: if you want to retain the height view set for your tracks when a project is closed and re-opened, right-click on the track header and choose “Lock Track Height to.” You can choose “Custom” as the size for any track height you may want other than standard sizes.

TIP: You can also use the option key to adjust heights for all selected tracks or Command-option to adjust all selected tracks.

Fairlight Configuration Presets

You can store and recall complete configuration presets for the Fairlight page, or individual areas of it, using the Presets Library functions, found in Fairlight > Presets Library.

For more more information on using the Presets Library, *see Chapter 168, "Setting Up Tracks, Busses, and Patching."*

Undo and Redo in DaVinci Resolve

No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you've taken or commands you've executed, and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you've done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo "stacks" to help you manage your work.

- The Media, Edit and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack so that you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack so that you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you're in.

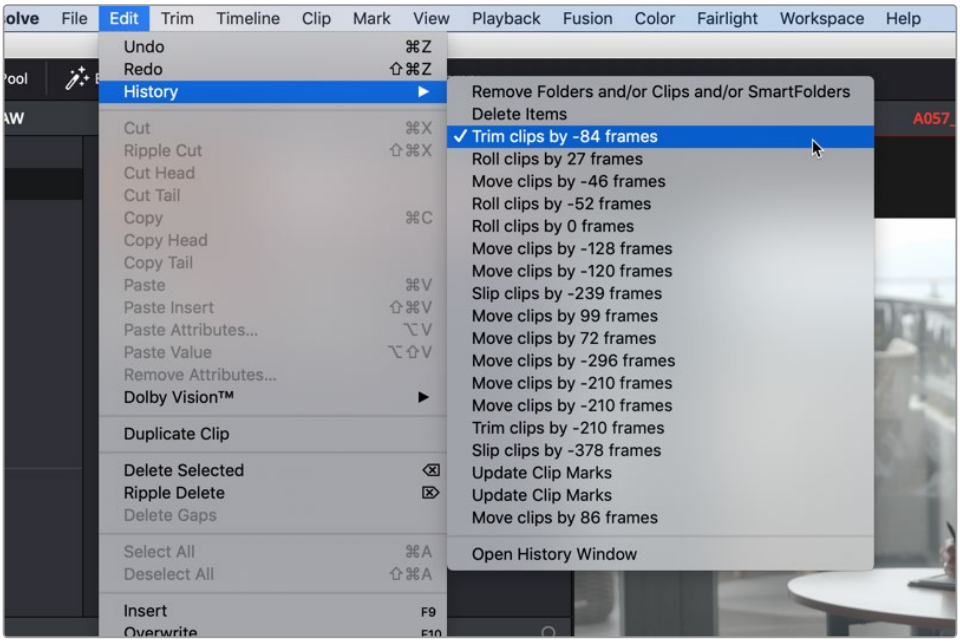
To simply undo or redo changes you've made one at a time:

- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.

You can also undo several steps at a time using the History submenu and window.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you've done.
2. Choose an item on the list to undo back to that point. The most recent thing you've done appears at the top of this list, and the change you've just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what's possible. However, if you've undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.

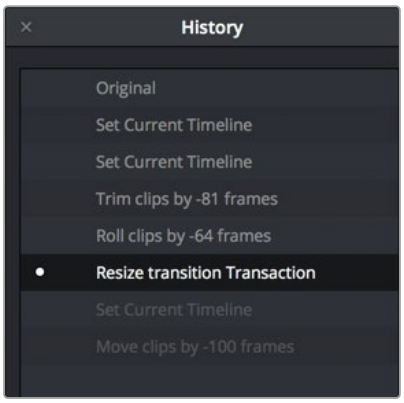


The History submenu, which lets you undo several steps at once

Once you've selected a step to undo to, the menu closes and the project updates to show you its current state.

To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.
2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you've done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.



The Undo history window that lets you browse the entire available undo stack of the current page

3. When you're done, close the History window.

Chapter 168

Setting Up Tracks, Busses, and Patching

One of the first things you need to do when you're setting up a new project for mixing in the Fairlight page is to define the audio tracks and busses you'll need to route and combine the elements of your mix.

This chapter covers how to create audio tracks and how to use busses to manage your mixes in the most efficient possible way. However, the Fairlight page gives you the flexibility to add or change your set up at any time; you can also concentrate on being creative and deal with any required housekeeping as your mix evolves.

Fairlight's FlexBus structure supports bus-to-bus, track-to-bus, or bus-to-track signal routing, along with expanded Dolby Atmos capabilities, including import, export, and manipulation of Atmos ADM files.

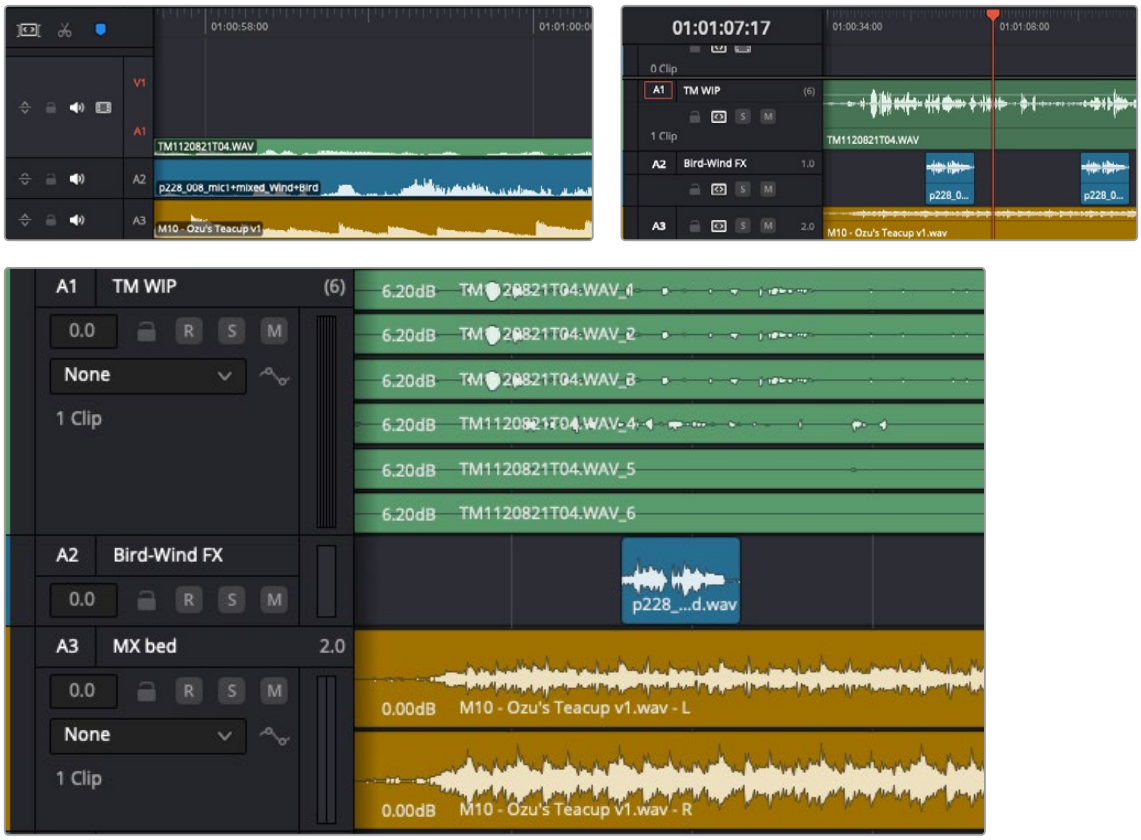
Audio Tracks

Each audio track in a DaVinci Resolve timeline corresponds to a single channel strip on the Mixer's left side. Depending on how an audio track has been configured, each audio track is assigned a specific audio format, such as mono, stereo, 5.1 or 7.1 surround, or Dolby Atmos. Track routing allows multiple audio channels within the clips on a track to be correctly routed to the proper audio output for monitoring and rendering via the lanes that can be seen within each track on the Fairlight timeline.

Audio tracks in DaVinci Resolve often contain multiple channels from a given clip, but how those individual audio channels are displayed depends on the page:

- The Cut and Edit pages display a single clip "lane" per audio track in the Timeline, regardless of how many channels the clips on that track are representing. The waveform displayed is a composite, showing a mix of the various channels within the clip.
- This can make it easier to work with multichannel tracks without the distraction of viewing multiple channel lanes, which could make things look a lot "busier." However, the tradeoff is that detailed activity on any of the various channels on that track are not seen.
- The Fairlight page displays the same number of tracks as the Edit page, but each track on the Fairlight page is divided into lanes, which shows each individual channel of a clip's audio. This additional visual information can help with editing and mixing.



(Top) 6 channel and stereo audio in the Cut and Edit pages represented by single composite tracks. (Bottom) The same audio in the Fairlight page shows the six channel and stereo tracks with multiple lanes that correspond to each of the file types.

Now that you understand how tracks work on the Fairlight page, the next important concept you need to understand in order to unlock the power of the Fairlight page is FlexBus, which lets you combine multiple audio tracks in different ways.

What Is a Bus?

A bus is simply a common signal connection point in an audio mixer. Busses can be mono, stereo, or any larger format, like 5.1 or Dolby Atmos 9.1.6 (where 16 audio signals are used). Bussed connections are mixed together into a single signal that can be controlled via a single bus channel strip. For example, by default a single bus called “Bus 1” combines the levels of every clip edited onto every track of a timeline into the mixed signal that is output to your speakers or headphones.

You can use busses in creative ways to organize mixing of tracks in a timeline. For example, if you have five audio tracks that have all of the edited dialogue audio clips for a particular program, you can route the output of all five dialogue tracks to a dedicated submix bus. This allows the combined levels from all the contributing dialogue tracks to be processed, adjusted, and mixed at once using a single channel strip’s controls.

You can use multiple busses to organize a mix, including routing submix busses into other “main busses.” Individual tracks can be routed to submix busses, then multiple submixes can be routed to one or more “main output” busses. For example, you could have four submix busses, one for German dialogue, one for English dialogue, one for Music, and one for Effects. You could route the German, Music, and Effects submix busses to a Main 1 bus to output the German version of the program, and route the English, Music, and Effects submix busses to a Main 2 bus to output the English language version of the program.

Surround Panning and Bussing

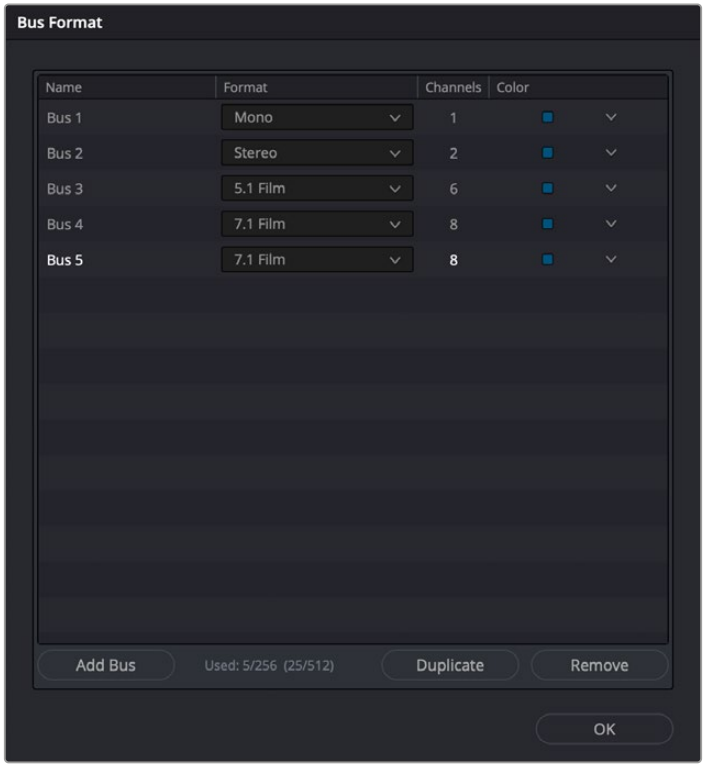
When working on surround or immersive formats, audio tracks from the Timeline are routed to busses via each channel strip’s multi-format surround panner, so busses can be configured to accommodate specific audio formats, such as mono, stereo, LCRS, 5.1 surround, or 7.1 surround, and immersive formats, such as Atmos. By using multiple bus routing, you can even output different formats simultaneously.

Bus to Bus Routing and Mixing

Fairlight’s FlexBus structure offers complete user flexibility for bus types and signal routing, allowing completely user-definable bussing, and making it possible to patch outputs and/or sends in any way you need, as dictated by your project. Each track can output to up to ten busses and sends with additional level and pan controls to a further ten busses. Busses can be sent to other busses up to six layers deep, facilitating complex stem building, processing, and allowing discrete deliverables.

User-definable busses allow for bus-to-bus, bus-to-track, or track-to-bus routing, with each bus having the ability to pass signals from mono to fully immersive formats, such as Dolby Atmos. As with any and all of the track types in Fairlight, these bus types can be changed at any time if needed.

The power of the FlexBus system is that it allows users to direct signals to many different places at one time, achieving complex mixing scenarios. Perhaps you need to generate two mixes that are identical in content but need to be of different output levels. You can designate two mix busses, one with an output level of -2dB true peak and one with an output level of -10dB true peak. The final mix signal is sent to one bus that is then broken into two more busses, one with a limiter set to -2dB and one set to -10 dB, creating these two different mixes at one time.



The FlexBus structure allows for many different bus track types to be created or changed.

Using Legacy Fixed Bussing

If you want to work using the previous method of Fixed Bus mapping, you can do so for new projects by opening the Fairlight panel of the Project Settings, and turning on the “Use fixed bus mapping” checkbox.

If your project has Fixed Bussing enabled and you want to change to FlexBus, then uncheck the “Use fixed bus mapping” checkbox. Note that once you have made the change it will not allow you to change it back to legacy bussing.

> For more information *see Chapter 174, “Mixing in the Fairlight Page.”*

Converting Older Fixed Bus Projects to FlexBus

Older Fixed Bus projects can be converted to FlexBus by doing the following:

- Open Project Settings > Fairlight.
- Under the Bussing heading, uncheck “Use fixed bus mapping.”
- A dialog will appear allowing you to convert the project to FlexBus.

Busses in Nested Timelines

When you nest a timeline inside another timeline that has busses set up for mixing in the Fairlight page, all bus routings continue to work as intended within the nested timeline, which exposes all channels via the default main bus (Bus 1) in the enclosing timeline. In this sense, the audio of the nested timeline can be considered to be a submix that outputs its resulting audio to the audio track it’s

edited onto. However, you can also decompose your nested timeline into its own bus structure within the main timeline you've imported into, exposing all of the original tracks as they were.

> This is a very powerful feature for combining work done at different times or by different contributors, *see Chapter 174, "Mixing in the Fairlight Page."* in section *Nested Audio Timelines* for more information.

Exposing Bus Tracks in the Timeline

You can expose any bus as a track in the Timeline. This makes it possible to view and edit automation that is applied to parameters on that bus.

To show a bus in the Timeline:

1. Enable the Toggle Automation button on the Fairlight toolbar. All busses are visible by default.
2. If you want to hide a bus, open the Index, and click the eye button for the bus you want to hide in the Timeline.
3. If you want to work with automaton on a bus, choose the desired automation curve you want to view from the dropdown menu in the track header controls.

Controlling Signal Flow

A good process for setting up editing and mixing in the Fairlight page is:

- Organize and configure the tracks on your timeline as required.

  For example, clips well organized on tracks, set track types, color, grouping, etc.
- Create the busses needed to organize the desired signal flow in the mix.
- Route the audio tracks, or any submix busses to the desired bus destinations for the mix layout.

Defining Audio Track Types

If you decide to create a new audio track, you have to choose what kind of audio track it will be. Right-clicking in the bottom audio portion of the Timeline track header reveals a contextual sub-menu that lets you create different kinds of audio tracks.

- **Mono:** Holds a single channel with only one lane.
- **Stereo:** Holds stereo left and right channels, with two lanes.
- **3.0:** Holds three channels, with three lanes in either LRC (Left, Right, Center) or LCR (Left, Center, Right) format.
- **4.0:** Holds four channels, with four lanes in either LRCS (Left, Right, Center, Surround), LCRS (Left, Center, Right, Surround), or Quad format.
- **5.x:**

  5.0 holds five channels corresponding to a 5.0 surround mix, for a total of five lanes. For broadcast, SMPTE specifies Left, Right, Center, Surround Left, and Surround Right. For cinema distribution (5.0 Film), these tracks are ordered Left, Center, Right, Left Surround, and Right Surround.

  5.1 holds six channels corresponding to a 5.1 surround mix, for a total of six lanes. For broadcast, SMPTE specifies Left, Right, Center, LFE, Surround Left, and Surround Right. For cinema distribution (5.1 Film), these tracks are ordered Left, Center, Right, Left Surround, Right Surround, and LFE.

- **7.x:** 7.0 holds seven channels corresponding to a 7.0 surround mix, for a total of seven lanes. For broadcast, SMPTE specifies Left, Right, Center, Left Surround, Right Surround, Back Left Surround, and Back Right Surround. For cinema distribution (7.0 Film), these tracks are ordered Left, Center, Right, Left Surround, Right Surround, Back Surround Left, and Back Surround Right.

  7.1 holds eight channels corresponding to a 7.1 surround mix, for a total of eight lanes. For broadcast, SMPTE specifies Left, Right, Center, LFE, Left Surround, Right Surround, Back Left Surround, and Back Right Surround. For cinema distribution (7.1 Film), these tracks are ordered Left, Center, Right, Left Surround, Right Surround, Back Surround Left, Back Surround Right, and LFE.
- **Adaptive:** Holds up to 24 audio channels, each with its own lane within the track. An adaptive audio track can hold clips with different combinations of channels, up to the maximum number of channels allowed within that track. The number of channels allowable on a particular Adaptive track is user-definable (1–24) at the time that track is created. If you edit a clip with more channels into an Adaptive track that was created to hold fewer channels, the extra clip channels are muted.
- **Dolby Atmos:** There are several Dolby Atmos formats available: 5.1.2, 5.1.4, 7.1.2, 7.1.4, and 9.1.6. The naming of the channel configurations in the Dolby Atmos format includes the height channels in the nomenclature. Channel configurations are presented as three digits separated by periods, such as 7.1.4. The first digit describes the number of main, or ear-height monitoring channels that surround the listener. The second digit describes the number of subwoofer channels. The third digit describes the number of height channels, which are speakers positioned on, or in the case of a soundbar pointed to, the ceiling.

NOTE: The Dolby Atmos bus formats of 9.1.4, 9.16, and 22.2 are only available in DaVinci Resolve Studio and also require that Dolby Atmos be enabled in Preferences > Video and Audio I/O > Immersive Audio.

Adding Tracks (Contextual Menu)

There are two commands related to adding tracks in the right-click contextual menu on any audio track's header controls:

- **Add Track:** Adds a single audio track of the type you choose from a submenu.
- **Add Tracks:** Lets you insert as many tracks as you like, designating the track type and position in relation to other tracks in the Timeline.

Rearranging Tracks

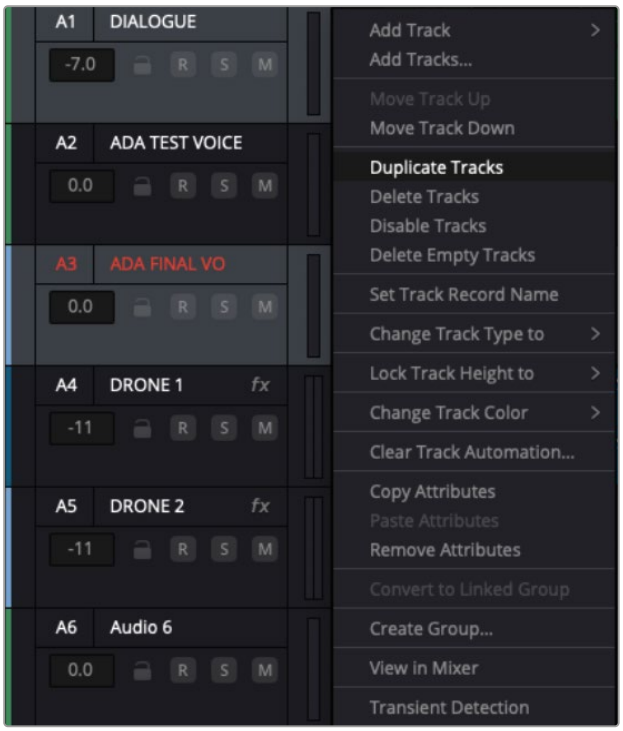
You can rearrange tracks by right-clicking in a track's header area and choosing either Move Track Up or Move Track Down in the contextual menu that appears. You can also move tracks in the Index by grabbing them and moving them to the desired position. This method works when moving multiple tracks at once.

Duplicating Tracks

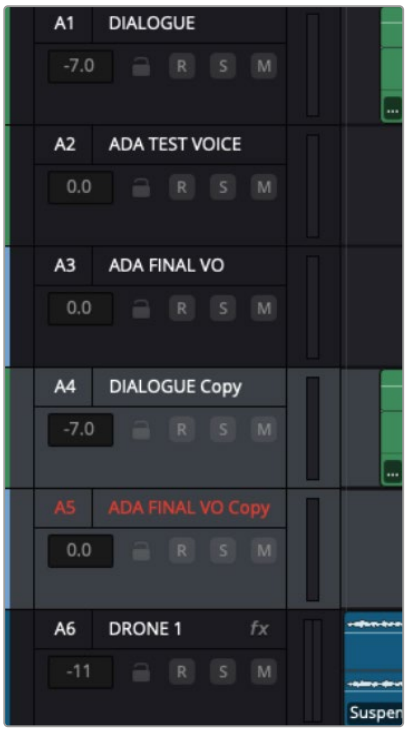
Tracks can be duplicated by right-clicking a track header and choosing "Duplicate Track" from the contextual menu.

You can duplicate multiple tracks simultaneously by selecting them, right-clicking any track header in the group, and choosing "Duplicate Tracks" from the contextual menu.

The names of duplicate tracks will be appended with the word "copy."



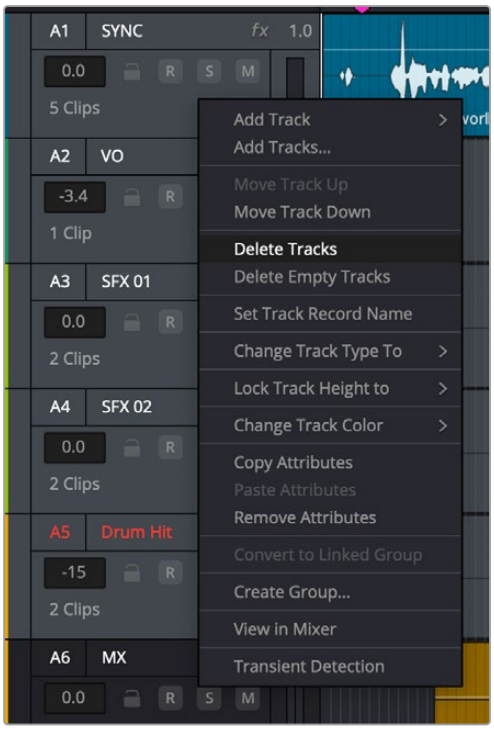
Timeline contextual menu - Duplicate Tracks



Duplicated tracks with appended names

Deleting Tracks

Right-click within a track's Timeline header and choose Delete Track. If there are clips on a track you remove, they are also deleted from the Timeline, but preserved in the Media Pool.



Timeline contextual menu - Delete Tracks

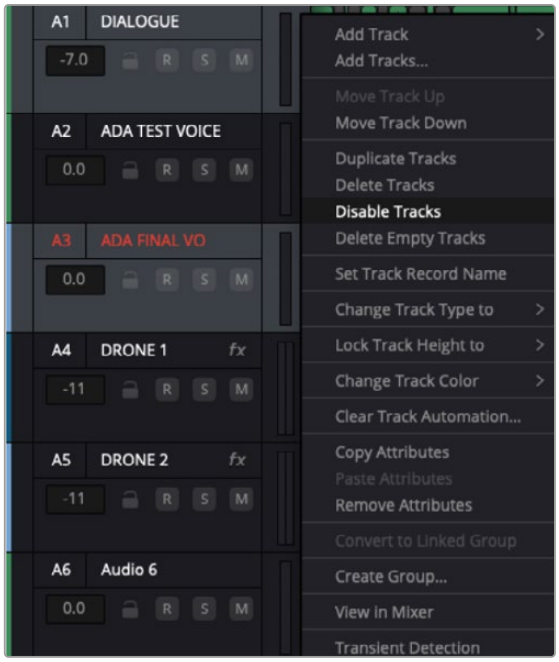
You can delete a selection of tracks in the Fairlight timeline by right-clicking any selected track header and selecting Delete Tracks from the contextual menu.

You can remove all empty audio tracks in the Fairlight timeline by right-clicking any track header and selecting Delete Empty Tracks from the contextual menu.

Disabling Tracks

You can disable an audio track by right-clicking its track header and choosing Disable Track from the contextual menu.

To disable multiple tracks simultaneously, select them, right-click any track header in the group, and choose Disable Tracks from the contextual menu.



Timeline contextual menu - Disable Tracks

Disabled tracks

To reenable your tracks, repeat one of the selection processes based on the number of tracks, and choose Disable Track or Disable Tracks from the contextual menu.

Changing Track Type

If you had set up your timeline with one kind of audio track, but you discover you actually need a different type, you can change it at any time. Just right-click anywhere in that audio track's Timeline header, and choose an option from the Change Track Type To submenu of the contextual menu.

Link Grouping

The Link Group function allows you to link mono tracks of material that are related and manipulate them as a one entity controlled by a single fader on a single channel strip. Only mono tracks can be used to create a link group; other track types such as stereo, 5.1, 7.1, Atmos, or Adaptive cannot be used.

Unlike a multi-channel track with lanes, a link group of mono tracks functions as independent, editable tracks in the Timeline. However, each track is mapped when choosing a track type, using one of the standard multi-channel mappings (stereo, 5.1, 7.1, Adaptive).

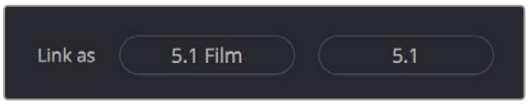
Link groups are extremely useful. For example, if you've been given independent ".L/.R" sides of a stereo mix, or a set of six independent related audio files that need to be assembled as a single 5.1 surround mix, or when you have surround channels that need to be specifically re-edited on a channel by channel basis.

To create a Link Group from individual mono tracks:

1. Create two or more Mono audio tracks that you want to group together. If you need to create a link group with a specific channel mapping, such as 5.1, make sure you create enough tracks (in this case, 6).
2. Choose Fairlight > Link Group.
3. When the Link Group dialog appears, mono audio tracks are represented by active buttons (all other track types are disabled, since they can't be linked). Click to enable the button of every track you want to include in the link group you're about to create. The available track type mappings when creating your group depends on how many tracks you've selected.

Selecting six tracks to use for creating a link group

4. After you've selected all the tracks you need, click one of the available "Link as" buttons below. In this example, six tracks have been selected, so you could click 5.1 Film or 5.1.



When you select enough tracks, you can create groups linked as specific surround mappings.

Afterwards, the tracks you selected should turn into a single block, showing they've been linked.

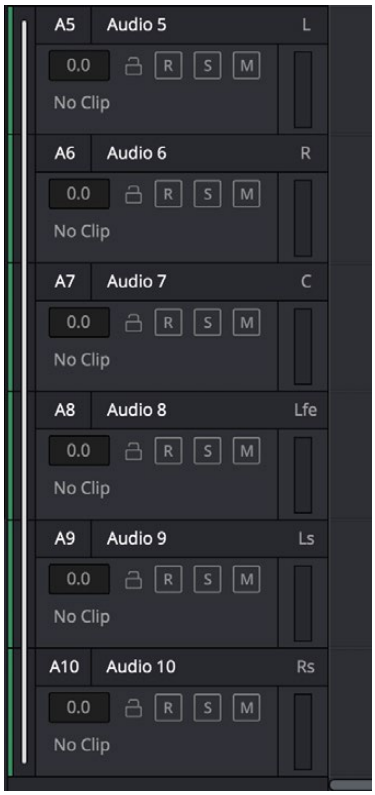
The Link Group window shows the link indicator line next to the track names.

Depending on the number of mono channels selected, Fairlight will offer possible linking options. For instance, when ten channels have been selected, both Atmos 7.1.2 and 5.1.4 are option choices.

The Link As option is dependent on the number of channels being linked.

5 Close the Link Group window when you're finished.

Once you've created a link group, you'll see a single bar on the left side of the headers, spanning the group. If the tracks are tall enough, each will be labeled, indicating its assigned channel based on the track mapping chosen in step 4. For example, with a 5.1 surround mapping, L, R, C, LFE, Ls, Rs, and so on. You also have the freedom to edit additional or different contributing elements of a surround mix into the appropriate track that represents that channel.



Tracks in a Link Group are labeled to identify which track corresponds to which surround channel.

Working Separately with Multichannel Audio File Elements

If you've edited a multichannel audio clip onto a multichannel track, you can convert that track and its contents into a Link Group of mono tracks, each of which contains a single clip for that track's channel. This can be useful if you need to fix a multi-channel surround audio clip with an incorrect track mapping. You can convert it into a Link Group, at which point you can easily rearrange the channels.

To create a Link Group from a single multichannel timeline:

Right-click the track header of a multichannel audio track, and choose Convert to Linked Group from the contextual menu. This automatically creates one new audio track for each channel, all of which are linked together. For example, converting a 5.1 audio track results in six new tracks with six individual audio clips (one for each channel), all of which are linked together.

If necessary, you can also unlink a linked group to turn it back into independent mono tracks.

To unlink a Link Group:

1. Choose Fairlight > Link Group.
2. When the Link Group dialog appears, select the link group you want to unlink.
3. Click Unlink.
4. Close the Link Group window when you're finished.

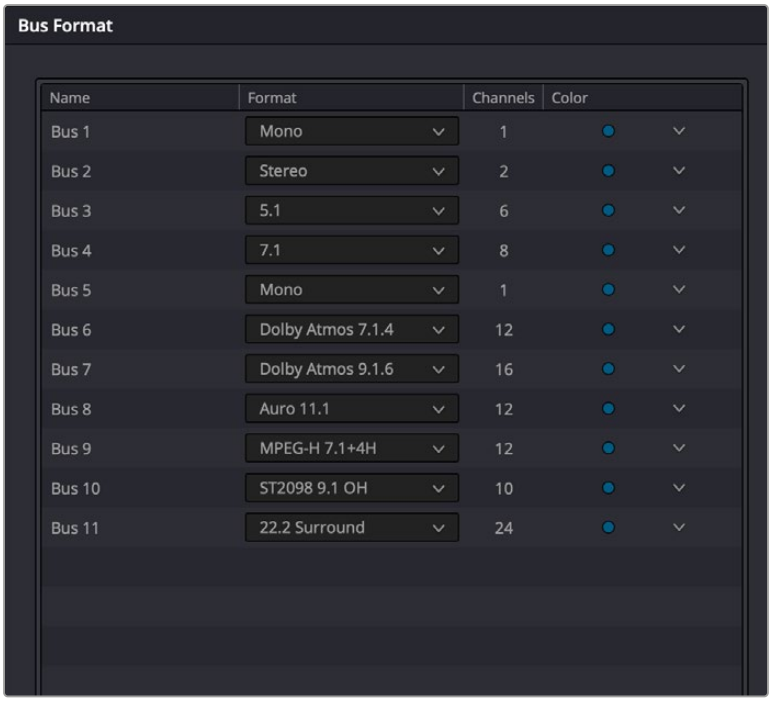
SMPTE and Film order Standards

The variations of routing of the multichannel files are due to the path order of SMPTE or Film standards. They are:

- **5.1 film order:** L, C, R, Ls, Rs, LFE
- **5.1 SMPTE order:** L, R, C, LFE, Ls, Rs
- **7.1 film order:** L, C, R, Lss, Rss, Lsr, Rsr, LFE
- **7.1 SMPTE order:** L, R, C, LFE, Lss, Rss, Lsr, Rsr

Creating Busses

Choosing Fairlight > Bus Format opens the Bus Format window, which lets you create the busses you need (up to the limitations of your system) to organize the tracks and channels of your program.



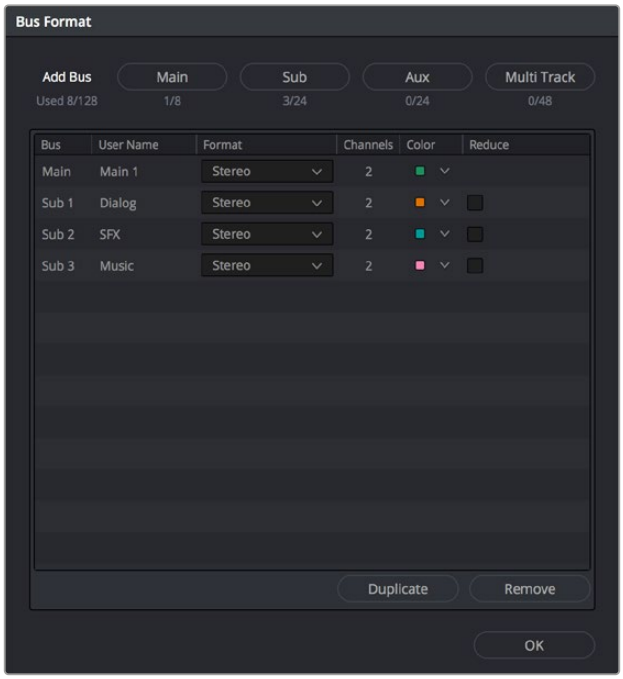
The depth of options in the FlexBus system

The Bus list lets you rename the bus, choose the format of each bus (a dropdown menu appears in the Format column of each entry of the list), shows the number of channels associated with a bus, and lets you color-code each bus (a Color dropdown lets you choose that bus's color). Simply click any item on the Bus list to select it, and choose different options from the Format and Color dropdown menus, or click on the Name of any bus to select it, and type a custom name.

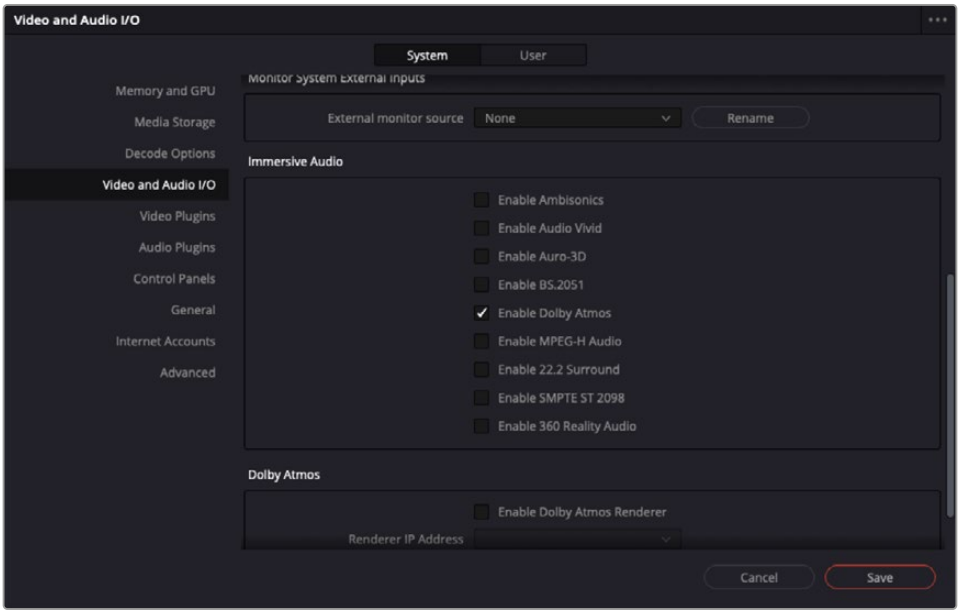
At the bottom of the list are three buttons that let you Add Bus, Duplicate, or Remove selected busses. When you're done modifying the available busses, you can click OK to accept the changes and close the Bus Format window, or Cancel to close the window without any changes (although all pre-existing busses remain in place). The bottom button row also has a Used tally of what has been used and what is available for your workstation.

Immersive Formats (Studio Version Only)

To turn on the immersive formats, go to Preferences > Video and Audio I/O > System Panel > Immersive Audio, and choose from among the appropriate options. Once enabled, the various immersive bus formats are available in the Bus Format panel's Bus list.



The legacy Bus Format window lets you add busses to the mixer.



The Video and Audio I/O panel lets you enable or disable Immersive Audio options.

Legacy Fixed Bussing

Working with the FlexBus topology is highly recommended for its flexibility. In addition, some newer features are only available using FlexBus. At some point, however, you may need to work with legacy Fixed Bussing in a new project. To use Fixed Bussing in a newly-created project, prior to adding any timeline, open Project Settings > Fairlight, and under the Bussing heading, check “Use fixed bus mapping.” Now all bussing is handled with the legacy Fixed Bus topology.

Bus formatting with Fixed Bus

The legacy Bus Format window has four buttons that let you create the various Fixed Bus types. Creating a new bus, whether it’s a Main, Sub, Aux, or Multi Track, adds the new bus to the list that appears beneath.

The legacy Bus list works the same as the FlexBus list with choices for rename, format, color code, and so on, and buttons that let you Duplicate or Remove selected busses.

When you’re done modifying the available busses, you can click OK to accept the changes and close the Bus Format window, or Cancel to close the window (although any busses you’ve made remain in place). The bottom button row also has a Used tally of what has been used and what is available for your workstation.

Assigning Busses

Once you’ve created one or more busses, you can assign different tracks to specific busses or perhaps also busses to busses, busses to tracks, and the final Main bus destinations.

Bus Assignment Using the Mixer

You can easily assign your track(s) to any available busses simply by using the plus (“+”) icon on a Mixer channel strip:

- Select a mixer channel, and click on the plus (“+”) icon in the Bus Output or Bus Sends section.
- In the dropdown menu, choose the desired destination.
- A rectangle appears with the name of the bus, and the bus is now assigned.

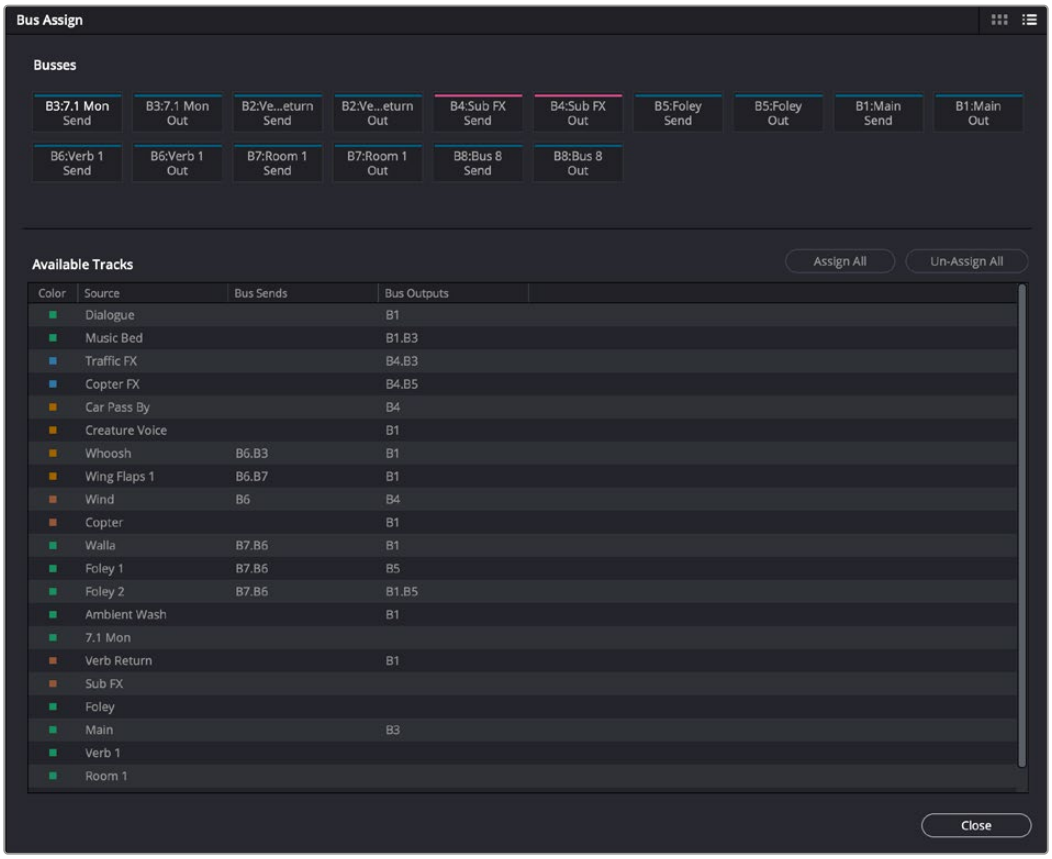
Bus routing dropdown menu on a channel strip

TIP: You can quickly assign a bus to any selected group of tracks, or to all tracks, by holding down the Option key (Mac) or the Alt key (Windows) for all selected tracks or Command-Option (Mac) or Control-Alt (Windows) for all mixer channel strips prior to performing the operation. These shortcuts can save a lot of time in your workflow.

The Bus Assign Window

When you have a lot of busses or tracks to handle, the Bus Assign window lets you to easily manage connecting to all of them at once. Choose Fairlight > Bus Assign to open the window. Multiple bus assignments can be created within the dialog; these new assignments will be reflected in the Bus Outputs section on the channel strips in the Mixer.

The top shows the Send and the Out of each available bus, while the bottom shows a list of all available tracks and busses to connect to. The Bus Assign window defaults to List view, in which each bus and track is shown as a list, but by using the icon in the upper right of the window, it can be switched to Icon view, in which Available Tracks are shown as buttons.



Bus Assign window

Making Bus Assignments

Assigning Using List View

Click a button in the Busses section to select the Send or Out of that bus, and then click on any destination in the tracks/busses list below, or drag over a group of tracks or busses to assign to all of them. When assigned, the bus number will appear in the Bus Sends or Bus Outputs column.

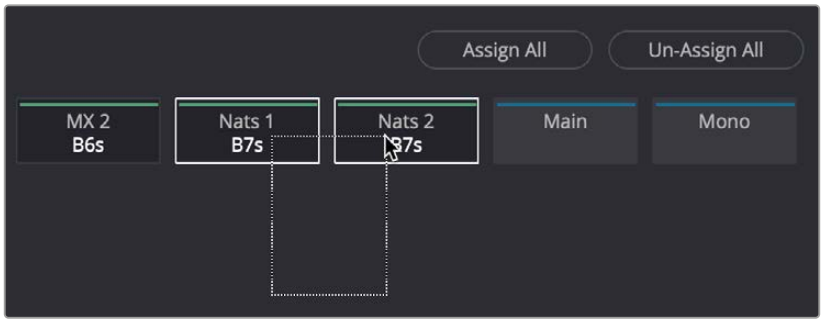
- **To assign every track, Sub, and Aux to a bus:** Click a button in the Busses section to select that bus, and then click Assign All.
- **To clear all track assignments from a particular bus:** Click a button in the Busses section to select that bus, and then click Unassign All.

  When you're done making bus assignments, click the Close button to close the dialog.

NOTE: While the dialog is open, you can undo any assignments you've made, one a time, or redo them, using Command-Z and Command Shift-Z respectively.

Assigning Using Icon View

- Click a button in the Busses section to select the Send or Out of that bus, and then either click on a target track button or drag a bounding box over all of the buttons for available tracks that you want to assign to that bus.
- Once assigned, the Available Tracks buttons display which bus they've been assigned to. When assigned, the Bus number will be followed by an "o" or an "s" to indicate if it's the send or the out of that bus.



Assigning multiple tracks to a bus in Icon view by dragging a bounding box

Setting Signal Paths

While bus creation and assignment allows you to submix tracks or route from one bus to another, you often need to route signals from individual, external sources to a track or bus. For example, if you need to record audio to a track, you need to patch the audio input on your hardware to the track you want to record to. Making this type of connection is called "patching" in Fairlight and is accomplished using the Patch Input/Output window, which is available on the Fairlight, Edit and Deliver pages, providing patching changes on any of these.

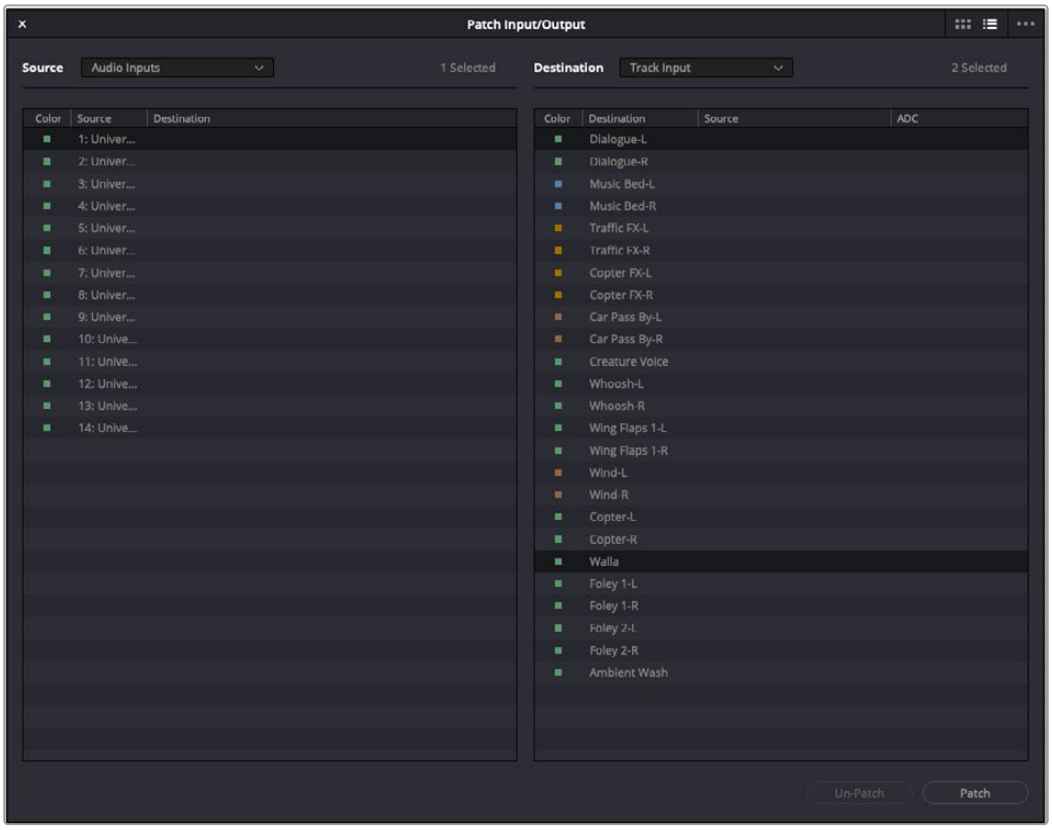
Using the Patch Input/Output Window

Choosing Fairlight > Patch Input/Output opens the Patch Input/Output window, which can be displayed in either List (default) or Icon view. This window is split into two halves, with the left half containing whichever Source controls you choose and the right half containing whichever Destinations you choose.

Creating a Patch

By default, the Patch Input/Output window shows the available Audio Inputs as the Source and the Track Inputs as the destination. This makes it easy to patch whatever audio source (such as a

microphone connected to a USB audio interface) to a specific audio track of the Timeline to prepare for recording. Patching and unpatching a source to a destination is straightforward. In the following screenshot, the Audio 1 Input from an audio interface is highlighted and is being patched to a track named “Walla.”



The Patch Input/Output window showing Source Audio Inputs and Destination Track Inputs

Patching a source to a destination:

1. Choose a type of source from the Source dropdown menu at the upper left-hand side of the window.
2. Click the item on the source list (or action button in Icon view) that you want to patch from on the left side of the Patch Input/Output window.
3. Choose a destination from the Destination dropdown menu at the upper right-hand side of the window.
4. Click the list item (or action button) of the destination you want to patch to on the right side.
5. Click the Patch button at the bottom right of the window. The source and destination will both display the connection they’re patched to.

To unpatch a source and destination pair:

1. Click a list item or action button corresponding to a source or destination you want to unpatch.
2. Click Unpatch.

Patching in Icon view

Choosing Source and Destination Controls

The Audio Source and Destination dropdown menus let you choose different categories of sources and destinations to patch together.

The following Source options are available:

- **Audio Inputs:** The available physical audio inputs on your workstation, for example the Fairlight SX-36 audio interface, MADI, third party interfaces (for example, USB or Thunderbolt), or system audio. Useful when patching to record audio.
- **Bus Out:** Any Busses.
- **Monitor Direct:** Monitor system Direct Out, routed post fold up/down matrix, pre the Monitor VolumeLevel/Dim/Mute.
- **Monitor Out:** Monitor system output. Post fold up/down matrix and Monitor VolumeLevel/Dim/Mute.
- **System Generator:** Provides various utility sources, including beeps and timecode generation:

  OSC: Provides a test oscillator. The oscillator controls appear in a floating window accessed via Fairlight > Test Tone Settings.

  Noise: Uses the Noise generator with choice of white or pink noise, which can be selected via Fairlight > Test Tone Settings.

  Beeps: Refers to beeps generated by operations on the ADR panel, with controls found on the ADR setup page.

  Timecode generator: Generates timecode when enabled and the transport runs, with controls provided in a floating window accessed via Fairlight > Remote Control Settings.

- **Track Direct:** Track Direct Out, can be pre or post the track fader, with an offset.
- **Track Reproduction:** This is the track playback signal, directly from disk, before any processing.
- **Dolby Atmos Renderer:** The output from the Dolby Atmos Renderer in the currently selected Atmos output monitoring format. There is also a parallel stereo binaural output to feed headphones.

The following Destination options are available:

- **Audio Outputs:** For example, the Fairlight SX-36 audio interface, MADI, third party interfaces (for example, USB or Thunderbolt), or system audio. Useful when patching to playback audio to speakers or headphone systems.
- **Talk Back:** The system for patching the General Purpose Input and General Purpose Output used for talkback.
- **Track Input:** The inputs to the available audio tracks in the current timeline, which are the inputs to the Record and Thru path.

- **Dolby Atmos Send:** You will need to patch this manually if you are creating original content. If you import a Dolby Atmos master file, the Send patching for the bed and object tracks will be created automatically. When an external Dolby RMU renderer is enabled, all sources patched to these sends will be mirrored on the physical outputs to the external renderer, as defined by the base audio outputs set in system preferences.

Legacy Fixed Bus Patching

If you choose to use the legacy Fixed Bussing in the Project Settings, the options appear a bit differently.

The following Audio Source options are available:

- **Audio Inputs:** The available physical audio inputs on your workstation, for example SX-36, MADI, or system audio. Useful when patching to record audio.
- **Monitor Direct:** Monitor system Direct Out. Post fold up/down matrix, pre the Monitor VolumeLevel/Dim/Mute.
- **Monitor Out:** Monitor system output. Post fold up/down matrix and Monitor VolumeLevel/Dim/Mute.
- **Main Direct:** Main Bus Direct Out; can be pre or post the Main bus master fader, with an offset.
- **Main Out:** Main Bus Out; always post the Main bus master fader.
- **Main Send:** Main bus master insert send.
- **System Generator:** Provides various utility sources, including beeps and timecode generation:

  OSC: Provides a test oscillator. The oscillator controls appear in a floating window accessed via Fairlight > Test Tone Settings.

  Noise: Uses the Noise generator with choice of white or pink noise, which can be selected via Fairlight > Test Tone Settings.

  Beeps: Refers to beeps generated by operations on the ADR panel, with controls found on the ADR setup page.

  Timecode generator: Generates timecode when enabled and the transport runs, with controls provided in a floating window accessed via Fairlight > Remote Control Settings.
- **Track Direct:** Track Direct Out; can be pre or post the track fader, with an offset.
- **Track Reproduction:** This is the signal from the track playback, before any processing.
- **Track Send:** Track Insert send.

The following Audio Destination options are available:

- **Audio Outputs:** The available physical audio outputs on your workstation. For example, the Fairlight SX-36 audio interface, MADI, third party interfaces (for example, USB or Thunderbolt), or system audio. Useful when patching to play back audio to speakers or headphone systems.
- **Main Return:** Main Bus master insert return.
- **Talk Back:** The system for patching the General Purpose Input and General Purpose Output for talkback.
- **Track Input:** The inputs to the available audio tracks in the current timeline, which are the inputs to the Record and Thru path.
- **Track Return:** Track insert return.
- **Dolby Atmos Send:** You will need to patch this manually if you are creating original content. If you import a Dolby Atmos master file, the Send patching for the bed and object tracks will be created automatically. When an external Dolby RMU renderer is enabled, all sources patched to these sends will be mirrored on the physical outputs to the external renderer, as defined by the base audio outputs set in system preferences.

Using a Channel Strip's Input Menu

The Input dropdown menu at the top of each track's channel strip in the mixer provides some shortcuts for patching different inputs and busses to the tracks of your mix. Each option in this menu makes the Patch Input/Output window appear with various Source and Destination selections automatically set up.

Input

The Patch Input/Output window appears set up to let you patch different inputs (such as the system audio input) to the tracks of the timeline. This makes it fast for setting up audio inputs in preparation for recording.

Bus

A shortcut to open the Patch Input/Output window (discussed previously in this chapter) that lets you patch Bus Out or Bus Sends to Timeline track channels.

Path Settings

This opens the Path Settings window for the track, which contains controls for adjusting the input level of audio signals coming from an input/output device.

The Path Settings window showing audio inputs and track inputs

These parameters are as follows:

Mic/Inst

Controls will only appear on this panel if you have connected channels 1 or 2 of a Fairlight SX36 audio interface to your system. If connected, you can remotely control all of the options (including level) for the mic/instrument inputs of the SX36 if they are assigned to the channel. If there is no connection to an SX36, the area is empty.

Record Level

- **Record:** This button is linked and identical to the Record Enable button on the channel strip; here for convenience. If you hit one, it will enable the other.
- **Thru:** Lets the input signal to pass into the mixer without enabling a record path. This is ideal when you want a source signal to always be available and just want to monitor it.
- **Record Level:** Allows you to apply a digital gain adjustment to the record path to disk, post the output of your audio interface's analog-to-digital converter.

  Normally, this control should be left at 0.0 (no change, unity gain), as it affects the level you are recording to disk. It is best practice to use the level controls on your audio interface to control the input level into DaVinci Resolve in order to maximize audio fidelity. However, there might be a time where you need a bit more level, or may not have access to an audio interface's controls, and in those cases you can adjust the input.

Trim

- **Polarity:** This button inverts the polarity of the signal coming into the channel strip (sometimes referred to as “flipping the phase”).

  For example, you may have an input signal, like an explosion, where the transient attack of the signal produces with a massively positive-going waveform (where the waveform mostly appears above the zero line).

  If you invert the polarity, the signal will now be mainly negative-going and the waveform will be concentrated beneath the zero line. Inverting polarity is sometimes used to more closely align signals from multiple microphones and can be used creatively to affect frequency response of such a signal.

- **Trim Level:** The Trim knob lets you adjust the level of the signal coming “off of disk” during playback to optimize the level feeding effects and the busses. This is helpful when you want to slightly trim an otherwise perfect element up or down in your mix.

  Trim adjustments are applied post the recorded signal and Track FX (which processes directly “off of disk”), and pre all other effects, and do not affect the recording level.

Direct Output

Each audio channel strip can enable a direct output that can be used to feed any other input destination. You can patch this source using the Track Direct choice in the Patch Input/Output dialog via the Source dropdown.

For more information *see Chapter 168, “Setting Up Tracks, Busses, and Patching.”*

- **On/Off:** Enables and disables the direct output.
- **Pre:** Sets the direct output tap-off point to be pre (before) the channel fader. On by default.
- **Level Control:** Sets the direct output level from minus infinity (fully off) to +10 dB. Default is 0.0 (unity gain).

Insert

This button is linked and identical to the Effects In button on the channel strip; here for convenience. Clicking this button in one location enables the other and switches all Fairlight FX, AU, or VST channel effects in or out of the signal path.

Input Menu with Legacy Fixed Bussing

When using the legacy Fixed Busing, the options there are a bit different. Here is how they look when that is enabled.

Input

The Patch Input/Output window appears set up to let you patch different inputs (such as the system audio input) to the tracks of the Timeline. This makes it fast for setting up audio inputs in preparation for recording.

Aux Bus

A shortcut to open the Patch Input/Output window (discussed previously in this chapter), which appears set up to let you patch different Aux busses to specific submix and Timeline track channels.

Sub Bus

A shortcut to open the Patch Input/Output window (discussed previously in this chapter), which appears set up to let you patch different Sub (submix) bus channels to specific Timeline track channels.

Main Bus

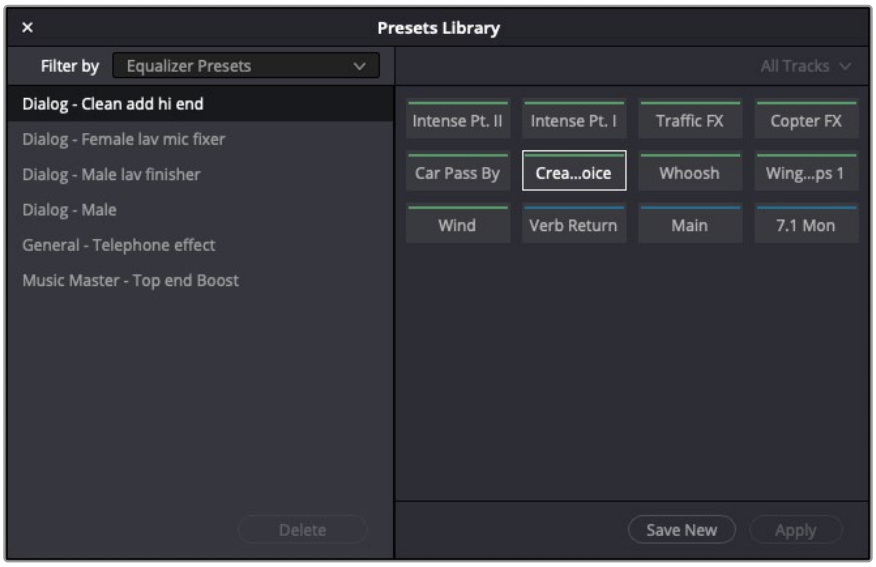
A shortcut to open the Patch Input/Output window (discussed previously in this chapter), which appears set up to let you patch different Main bus channels to specific Timeline track channels.

Path Settings

This option opens the Path Settings window, which contains controls for adjusting the input level of audio signals coming from an input/output device.

The Fairlight Presets Library

The Fairlight page offers a powerful and flexible preset system that allows you to store and recall presets for everything from the complete configuration of the audio page to individual presets for plugins. To access the presets library, choose Fairlight > Presets Library.



Fairlight Presets Library with stored presets on the left panel and destination tracks on the right

A Filter By dropdown menu on the upper left lets you choose the type of preset you want to work with.

Filter By menu of preset types

The choices are:

- **Equalizer Presets:** Presets for the built-in channel EQ.
- **Dynamics Presets:** Presets for the built-in Dynamics Processor.
- **Plugins Presets:** Fairlight FX, AU, or VST.
- **Global Track Presets:** All settings for a Mixer channel strip.
- **Global Bus Presets:** All settings for a Mixer bus.
- **Fairlight Configuration Presets:** Many parameters of the Fairlight page are stored as a preset including:
  - Track height.
  - What tracks are shown or hidden in the Tracks pane of the Index.
  - Split point in the Mixer.
  - Full Track vs. Small Track views in the Mixer.
  - Track Groups enable status.

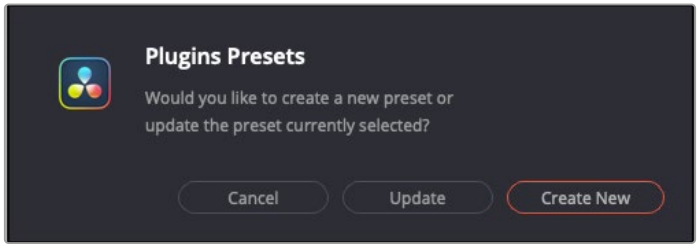
NOTE: Some items are not currently stored in Fairlight Configurations, such as which panels are shown (for example, Media Pool or Index), Meter Panel show/hide, Fairlight video window docking, and size if the video window is set to be floating.

Using the Presets Library

Select the preset type you want to work with from the Filter By dropdown menu on the left.

The tracks list on the right (which appears for most preset types) acts as both a list of sources that contain information you want to store and a list of destinations that you want to assign to when you have presets defined. To store and recall and assign presets:

- If you're storing a preset for the first time, select the source track in the tracks list on the right of the window that you'll be grabbing the preset type from (unless it's a Fairlight Configuration preset, which has no tracks to chose from, as it is global).
- Click the Save New button to save your preset.
- To load your preset onto another track, deselect any tracks currently selected in the track list on the right, and select the track(s) you want to assign to. Click Apply and the preset is loaded.
- To save a new version of an existing preset or update your present version, first choose a track in the track list that has your preset assigned to it. Then click the Save New button, and a dialog appears that allows you to choose to update the current version of the preset or save a new preset based on the current settings.
- To Delete a preset, select it in the list, and click the Delete button.



Update or Create New preset dialog

Chapter 169

Transport Controls, Timeline Navigation, and Markers

The Fairlight page has unique transport control, zooming, and scrolling options not found in the other pages of DaVinci Resolve that help you to work with audio more efficiently.

This chapter covers how to navigate around the Fairlight version of the Timeline.

Contents

Transport Controls and JKL Navigation 3583
Transport Controls 3583
Using JKL to Control Playback 3583
Dragging the Playhead to Scrub 3584
Looping Playback 3584
Loop Jog Scrubbing 3584

Setting the Zoom Level of the Timeline 3588
Scrolling Through the Timeline 3588
Using Flags 3589
Using Markers 3589
Adding Markers to Clips 3590
Adding Markers to Timelines 3590

Transport Controls and JKL Navigation

Because of the Fairlight page's audio-focused workflow, the transport and playback controls differ from those found in the Media, Edit, Color, and Deliver pages.

Transport Controls

Fairlight page transport controls

The Fairlight transport controls are also designed to mirror their counterparts on the Fairlight control panels. They include the following functions:

- **Rewind and Fast Forward:** Initiates accelerated playback through the Timeline in either direction. Pressing either of these buttons multiple times speeds up this motion, cycling through 8x, 24x, 60x, 150x, and 360x play speeds.
- **Play:** Plays forward. Identical to pressing the Spacebar or L keys while playback is stopped.
- **Stop:** Stops playback. Identical to pressing the Spacebar or K keys while playback is engaged.
- **Record:** Initiates recording if you have an audio source patched to a track, and if that track is enabled for recording. For more information about recording, *see Chapter 170, "Recording."*
- **Loop:** Toggles looped playback off and on. While looped playback is on, playback will loop at the end of the Timeline, and will also loop when you use the Play In to Out command, and will continue to loop automatically until you stop playback.
- **Automation controls:** This button exposes the automation toolbar.

> For more information about recording automation, *see Chapter 175, "Mix Automation."*

Using JKL to Control Playback

The JKL keyboard shortcuts are common to many editing applications, and experienced editors know these to be some of the most useful controls for playback and editing there are. Here's a list of the many different ways you can use these three keyboard shortcuts to play through clips and timelines as you work.

J	Plays 100% backward.
K	Stops playback.
L	Plays 100% forward.
Press J repeatedly	Increases backward play speed each time you press J, for a range of fast-reverse speeds.
Press L repeatedly	Increases forward play speed each time you press L, for a range of fast-forward speeds.
Shift-J	Plays in fast reverse.
Shift-L	Plays in fast forward.

K+J	Plays backward at slow motion (with slow motion audio playback).
K+L	Plays forward at slow motion (with pitch-corrected audio playback on OS X).
Pressing K while tapping J	Moves the playhead back one frame.
Pressing K while tapping L	Moves the playhead forward one frame.

If you're using Fairlight with the keyboard, then this will probably become one of the main ways you move the playhead around in DaVinci Resolve.

NOTE: All of the keyboard commands listed in this document are based on the DaVinci Resolve keyboard customization preset. There is great power in the remapping of keyboard commands to systems that may be more familiar to you like Premiere Pro or Pro Tools. However, if their keyboard command set does not offer the same commands as the DaVinci Resolve keyboard commands, they won't work the same. For instance, the Pro Tools keyboard preset does not support J-K-L timeline navigation.

Dragging the Playhead to Scrub

You can also drag the playhead left and right to scrub through the visible area of the Timeline by clicking and dragging anywhere within the Timeline ruler at the top of the Timeline, directly below the toolbar. If you're zoomed in at a reasonable level for editing, scrubbing the playhead using your pointer will result in smooth, tape-like slow and fast audio playback, giving you a great deal of precision while trimming audio.

Looping Playback

Two controls govern looping on the Fairlight page, similarly to how looping works on the Edit page.

- **Loop:** Command-Forward Slash (/). Toggles looped playback off and on. While looped playback is on, playback initiated with any of the following commands will loop automatically until you stop playback.
- **Play In to Out:** Option-Forward Slash (/). If you've marked a section of a clip or timeline with In and Out points, this command lets you preview how it will play.

Loop Jog Scrubbing

Currently available only on the Fairlight page, choosing Timeline > Loop Jog enables a brief sample preview to be heard while scrubbing the playhead through the Timeline. This can make it easier to recognize bits of dialog or music as you're quickly scrubbing through tracks, in situations where you're trying to locate specific lines or music cues. It also enables this brief sample preview to loop endlessly when you hold the playhead on a frame, so you can pause while scrubbing and hear (by default) the current 80 ms prior to the playhead as it loops.

A pair of settings in the User Preferences let you customize this behavior.

- **Loop Jog Alignment:** Three options let you choose whether you loop audio Pre the position of the playhead, Centered on the playhead, or Post the position of the playhead.
- **Loop Jog Width:** A field lets you choose how many milliseconds of audio to loop when Loop Jog is enabled. How many milliseconds of audio corresponds to one frame depends on the frame rate of the video. For example, at a frame rate of 25 fps, there are 1000/25 = 40 ms per frame, so the default value of 80 ms equals two frames of looping.

Moving the Playhead Using Timecode

You can use absolute or relative timecode entry to move the playhead in the Timeline. Timecode entry lets you move the playhead very precisely or jump to specific timecode values really quickly.

How to Enter Timecode Values

When entering timecode, type each pair of hour, minute, second, and frame values from left to right, with a period representing a pair of zeros for fast entry. The numbers you enter appear in the Timecode field at the upper right-hand corner of the Viewer with focus. When you're finished typing, press the Enter key to execute the timecode command. The rules for timecode entry are as follows:

- The right-most pair of timecode values (or period) you enter is always the frame number.
- A period to the left or to the right of any number you type is considered to be a pair of zeroes.
- A single period between two numbers is considered to either be a single zero or ignored if it's between two pairs of numbers.
- Any untyped pairs of values to the left of what you enter are assumed to be whatever those values were prior to the timecode you entered; this makes it easy to type partial timecode values even when the Timeline starts at hour one.
- It's not necessary to enter colons or semicolons.

IMPORTANT: With full length keyboards, you can use the number pad for implicit timecode entry without invoking the Go To Timecode action (=). When using a multicam or printer light operation, any already mapped number pad key will continue to invoke actions like switching angles or incrementing color values.

When using the number keys above the letters on a keyboard, you must first select Go To Timecode (=), or click in the field you wish to change before entering a new value.

Absolute Timecode Entry

Absolute timecode is entered simply by typing the timecode value you want to move the playhead to, and when you press the Return key, the playhead will move to that timecode value.

Here are some examples of absolute timecode entry using this method:

Original TC Value	User-Typed Value	New TC Value
01:10:10:10	15245218	15:24:52:18
01:10:10:10	2..	01:02:00:00
01:10:10:10	15	01:10:10:15
01:10:10:10	12	01:10:10:12
01:10:10:10	1.2	01:10:01:02
01:10:10:10	1115..	11:15:00:00
01:10:10:10	23...	23:00:00:00

Relative Timecode Entry

Relative timecode is entered by starting the timecode value with a plus (+) or minus (–). Adding a plus results in the value you type being added to the current timecode value for purposes of offsetting the playhead from its current position. Adding a minus will subtract the value you type from the current timecode value. Here are three examples of relative timecode entry:

User-Typed Value	Result
+20.	00:00:20:00 is added to the current timecode value.
+3..	00:03:00:00 is added to the current timecode value.
–5	00:00:00:05 is subtracted from the current timecode value.

Clip, Marker, and Track Navigation

The Up and Down Arrow keys are used to move the playhead from one edit point to the next in the Fairlight page Timeline, just as in the Edit page Timeline.

However, holding Command-Option down while using the Arrow keys gives you Fairlight page-specific behaviors that are used to navigate among clips, markers, and tracks in the Fairlight page in a way that's different than other pages of DaVinci Resolve but very useful to the way the Fairlight page operates. This section covers the basics.

Selecting Tracks

Which tracks are selected determine the behavior of the Arrow keys.

- **In Pointer mode:** You can select tracks by clicking or Command-clicking (to select multiple tracks) anywhere in the background area or on the track number of the track headers. If you click and drag in the track header, you can use a bounding box to select multiple tracks. Pointer mode will not select in unused areas of the Timeline.
- **In Range or Focus mode:** You can select tracks by clicking or Command-clicking anywhere either in the background area or on the track number of the track header, or in any unused area of the track itself in the Timeline. If you click and drag, you can use a bounding box to select multiple tracks.

Moving the Clip Selection

The Command-Option-Left and Command-Option-Right Arrow key shortcuts are used to move the playhead left and right in the Timeline, navigating from clip to clip or from marker to marker. How these keys function depends on whether or not one or more tracks is selected in the Timeline.

- **If no tracks are selected:** The Left and Right Arrow keys will jump the playhead from Timeline marker to Timeline marker. Clip markers will be ignored.
- **If one or more tracks are selected:** The Left/Right Arrow keys will jump the playhead among clip In points, clip Out points, and Timeline markers.

Moving the Track Selection

The Command-Option-Up and Command-Option-Down Arrow key shortcuts are used to move the track selection up and down in the Timeline, changing which tracks are selected. By changing which tracks are selected, you can alter which clip's In and Out points are used to jump the playhead around the Timeline.

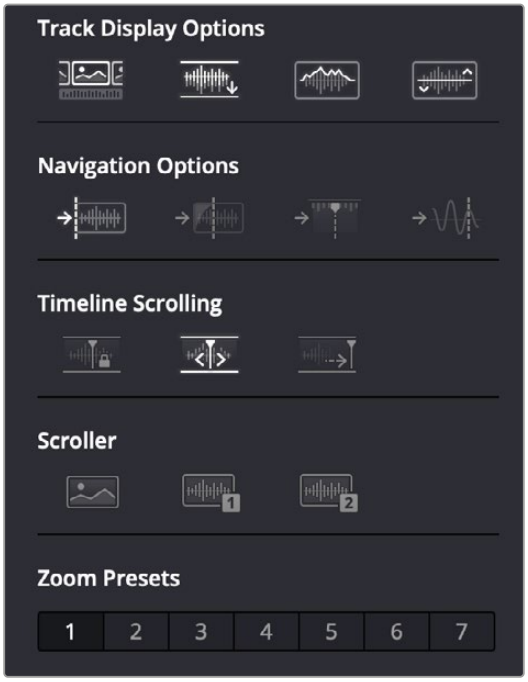
If no tracks are selected, then nothing happens.

Zooming and Scrolling

The Fairlight page has several methods of zooming into and out of the Timeline, and scrolling when you're zoomed to the point where your edited sequence of clips extends past the left and right edge of the visible timeline.

The Playhead

Zooming is always centered on the position of the Playhead. By default the Playhead moves along the Timeline as it plays. However, Fairlight offers the option of a Fixed Playhead where the Timeline moves while the Playhead remains centered.



The Playhead options are found in the Timeline Scrolling panel.

Setting the Zoom Level of the Timeline

Depending on how you like to work, there are several methods of zooming into and out of the Timeline.

- **Using the Vertical Zoom slider:** A pair of sliders at the right of the toolbar let you zoom vertically and horizontally. The first one lets you scroll vertically in order to see more detail in the height of your waveforms. If no tracks are selected, then zooming is centered on the top audio track in the Timeline. If one or more tracks are selected, then zooming is centered on the topmost selected audio track.
- **Using the Horizontal Zoom slider:** A pair of sliders at the right of the toolbar let you zoom vertically and horizontally. The second one lets you zoom horizontally in order to see more detail in the width of your waveforms.
- **Pressing Command-Equal (=) and Command-Minus (–):** Command-Equal (also referred to as Command-Plus) and Command-Minus let you zoom horizontally into the Timeline.
- **Use Shift-Z to Zoom to Fit:** Command-Z lets you zoom horizontally to fit all clips in your program to the available width of the Timeline.
- **Using scroll controls of your pointing device to scroll horizontally:** Holding the Option key down and using the scroll wheel (or scroll control) of your pointing device will zoom horizontally into the Timeline. Holding the Command key down and using the scroll wheel will move the Timeline earlier or later than its current time, without moving Playhead.
- **Using scroll controls of your pointing device to scroll vertically:** Holding the Shift key down and using the scroll wheel (or scroll control) lets you zoom vertically in the Timeline. In this case, if no tracks are selected, then zooming is centered on the top audio track in the Timeline. If one or more tracks are selected, then zooming is centered on the topmost selected audio track.
- **Using the Fairlight panel's Jog/Edit wheel:** If you have a Fairlight panel, you can hold the ZOOM button down while turning the Jog/Edit wheel to zoom into the Timeline at the position of the playhead.

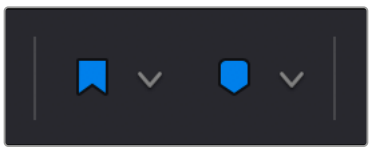
Scrolling Through the Timeline

However closely you're zoomed into the Timeline, if you're zoomed enough so that clips extend past the visible area of the Timeline, scroll bars appear below. If the playhead is offscreen, a small orange tic mark indicates its position relative to the entire timeline, which is represented by the total width of the scroll bar's background.

If you drag the playhead, or otherwise use any of the transport controls or playback key shortcuts to move through the Timeline, the contents of the Timeline refresh every time the playhead hits the left or right edge of what's visible.

Using Flags

Flags are meant to mark an entire clip, and they also flag every other clip in the Timeline that shares the same Media Pool source clip, making this a handy way of quickly identifying which clips in a given timeline come from the same Media Pool source. Flags are visible in every page of DaVinci Resolve, making them an excellent method of tracking media from page to page.



The Flag and Marker buttons and pop-ups.

You can apply multiple flags to clips, with a variety of colors to choose from. In addition to flagging specific media files, flags can be useful for sorting by column in the Media Pool, as well as a variety of other operations. Whenever you enter text into a flag, it displays a small dot that indicates there's more information inside of it.

Methods for flagging clips in the Fairlight page:

- **To flag a clip:** Select one or more clips, and either click the Flag button to flag that clip with the current color, or click the Flag pop-up in the toolbar to choose a different color and then click the Flag button. In the Edit page, flags appear in the Timeline superimposed in the name bar of each clip.
- **To remove all flags from a clip:** Select one or more clips with flags you want to remove, then click the Flag pop-up in the toolbar, and choose the top "Clear All" option.
- **To change the Flag color or remove individually:** Double-click the Flag icon on the clip and a Marker dialog box appears to change the Flag color, remove the flag, or make a note regarding the flag.

Using Markers

Markers are used to call attention to a particular frame within a specific clip. Markers can be individually colored, and can have customized name and note text. Whenever you enter text into a marker, that marker displays a small dot that indicates there's more information inside of it. Once placed, markers snap to In and Out points, edit points, the playhead, and other markers whenever snapping is enabled, making it easy to use markers to "measure" edits and trims that you make in the Timeline. Markers are visible in every page of DaVinci Resolve, making them an excellent method of tracking frames in clips and specific moments in the Timeline from page to page.

You can add markers to the Timeline (in the Timeline ruler) or to clips. The full procedures for placing and editing markers in the Fairlight page's onscreen interface are identical to those for the Edit page, so for more information, *see Chapter 41, "Marking and Finding Clips in the Timeline."* For now, here's a summary.

Adding Markers to Clips

The following procedures describe how to add markers to clips in the Timeline of the Media page.

To mark a clip in the Timeline, do one of the following:

- Select one or more clips you want to mark, then move the playhead to the frame of a selected clip in the Timeline, and click the Marker button in the toolbar (or press M) to place a marker at that frame, using the current color (if multiple overlapping clips are selected, you'll add a marker to all clips).
- To place a marker during playback and immediately open the marker dialog to enter a name or note within it, select one or more clips you want to mark, play through the selection until you want to place a mark, then press Command-M. Playback pauses until you enter some text and close the marker dialog again, at which point playback continues.
- Select one or more clips you want to mark, and then click the Marker pop-up to choose a different color, and click the Marker button.

Adding Markers to Timelines

You can also place markers of any color into the Timeline ruler to denote specific times for future reference, or add notes about issues you want to keep track of. You should note that all markers placed on clips or in the Timeline also appear within the Mini-Timeline of the Color page, making it easy to place notes to reference particular audio cues that might be valuable when editing or grading.

To mark the Timeline itself, make sure all clips are deselected, and do one of the following:

- Click the Marker button (or press M) to place a marker of the currently selected color in the Timeline ruler.
- To place a marker during playback and immediately open the marker dialog to enter a name or note within it, select one or more clips you want to mark, then press Command-M. Playback pauses until you enter some text and close the marker dialog again, at which point playback continues.
- Click the Marker pop-up to choose a different color, and click the Marker button.
- Right-click in the Timeline ruler and choose a marker color from the Add Marker submenu of the contextual menu.

Chapter 170

Recording

It's possible to record to one or more tracks on the Fairlight page, accommodating workflows as varied as editors recording scratch voiceover or temp sound effects, recording engineers recording narration, ADR, or foley as part of the audio finishing process, music studios recording orchestras for the music score, or garage bands recording their latest magnum opus.

While DaVinci Resolve is a comprehensive post-production environment for cinema and video, the Fairlight page can be used for any audio recording application you might have, from books on tape to live music to feature films and television.

Recording VSTi Instruments 3597

Setting Up to Record

Depending on how your workstation is set up, it's possible to simultaneously record to multiple tracks in the Fairlight page at once. How many tracks you can record to depend entirely on what hardware you have available. This section describes the process of recording to tracks in the Fairlight page.

Patching Inputs

Before recording audio anything, you need to use the Patch Input/Output window to patch an available audio input to a track.

DaVinci Resolve allows you to designate a full-time default input that is automatically patched to the track input when the R (Record Arm) button is clicked or manually patching in an audio input before record-arming it.

> If you don't have an audio interface connected, you can use your workstation's inputs to connect whatever audio device is set up as the default audio input on your system to the track you want to record on.

Automatic Input Patching

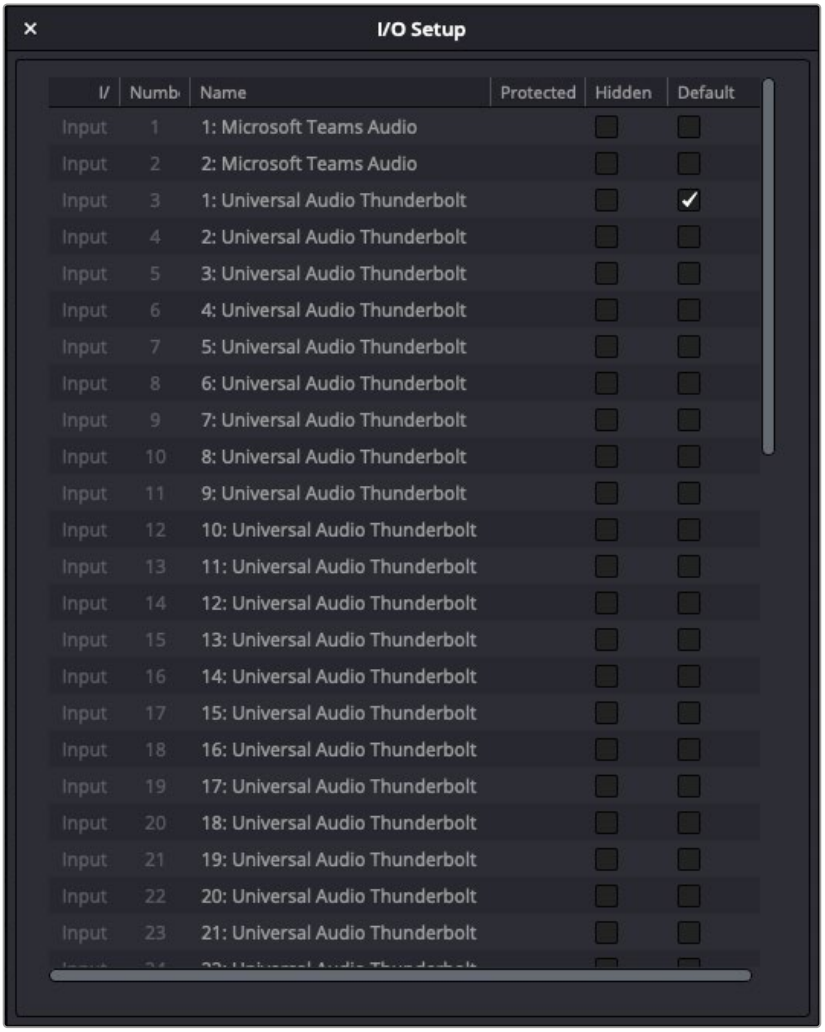
The steps in this section explain how you can configure DaVinci Resolve to automatically patch in a designated default audio input whenever you click the R (Record-Arm) button in the track header or mixer channel of a track you want to record on.

To set up Automatic Input Patching:

1. Click the Fairlight menu > Patch Input/Output.
2. When the Patch Input/Output panel opens, select Setup I/O Names in the Options menu in the upper-right corner. This opens the I/O Setup panel.

The Patch Input/Output Options menu

3. Place a checkmark in the Default column for the audio input you want to designate as the default track input source, then close the I/O Setup panel.



Default audio input selection in the I/O Setup panel

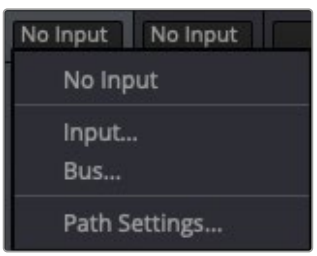
This input is automatically patched in when you record-arm any audio track using the R button in the Track header or Mixer channel. The audio input name will appear in the channel strip's input section.

Manual Input Patching

You can follow the steps below to manually select an input source without affecting the default audio input you may have already set up.

To manually patch in an auto input:

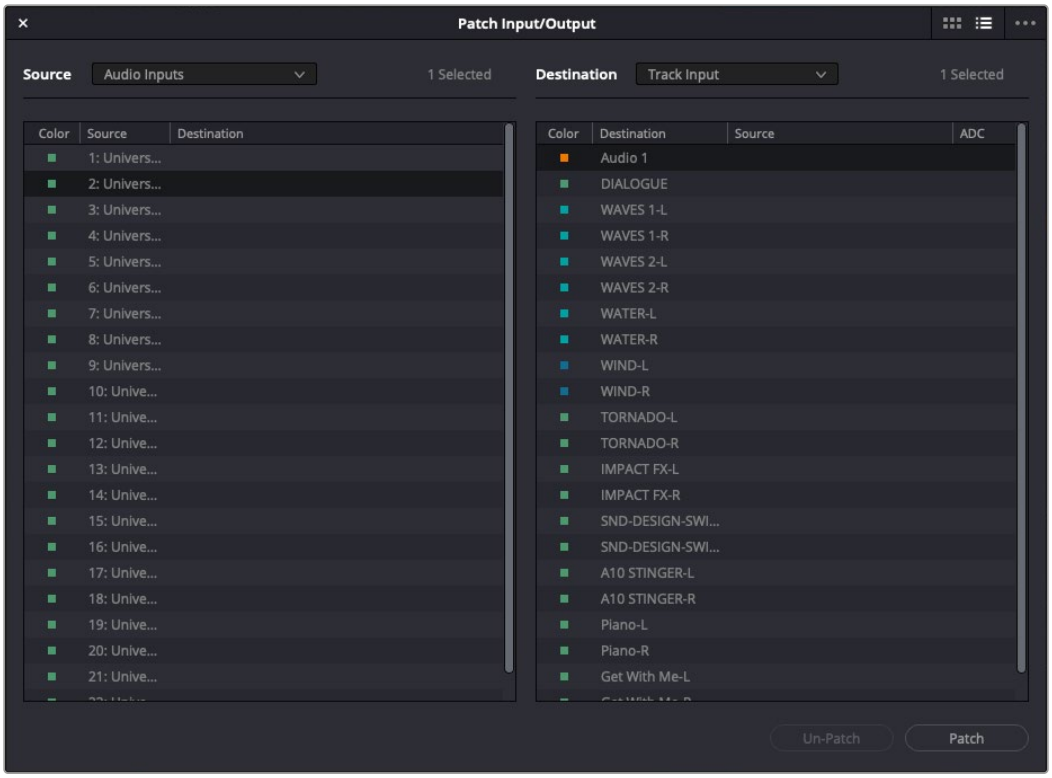
1 Open the Patch Input/Output pane by clicking the Input button at the top of the Mixer channel you want to record on and select Input. Alternatively, you can select Patch Input/Output from the Fairlight menu.



Mixer channel strip Input button menu

2 When the Patch Input/Output panel opens, select the audio input source and destination track input. You can repeat this step until you've patched all the inputs you want to record from to all the tracks you want to record to. You can patch as many inputs to as many tracks as your system can accommodate.

3 Click the Patch button in the lower-right corner of the panel.



The Patch Input/Output panel with an Audio Input and Track Input selected

Arming Tracks

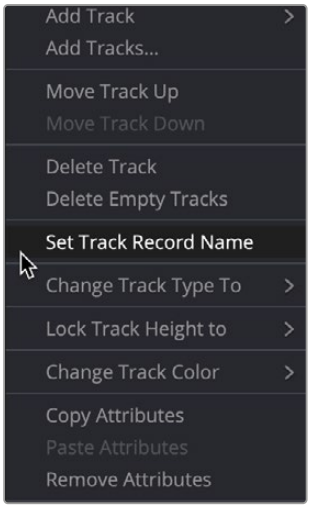
When you're ready to record on a track, click the R (Record Arm) button on either the Track header or corresponding Mixer channel.

Audio tracks cannot be record-armed unless they've been patched using one of the methods explained above.

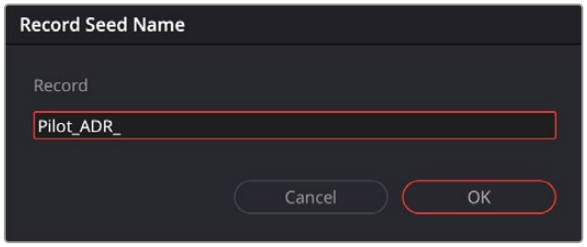
(Left) The Record Arm button activated on a Track header;
(Right) the Record Arm button activated on a channel strip

Record Name Prefix

A right-click on the designated record track header has the option to set a recording name prefix to the recordings for that track. This is a useful way to keep tabs of the various recordings required by your project. For instance, if recording ADR you can add a prefix for each character's recordings as in the example below for a character named Pilot.



Right-clicking a track header reveals the Set Track Record Name option



Example of a recording name prefix for a character called Pilot

Choosing Where to Record Audio Clips To

The process of recording in the Fairlight page creates new clips and generates additional media on disk. You can specify the location on disk where you want to save these recordings by opening the Capture and Playback panel of the Project Settings. In the Capture section use the Browse button, found underneath the "Save clips to" field, to choose a new location (a folder named "Capture" on your scratch disk is the default location).

To choose where the new clips that are created are placed in the Media Pool, simply open the Media Pool and select any bin in the Bin list, or create a new bin and select it if you want to put your recordings in their own location.

User-Selectable Input Monitoring Options

The Fairlight > Input Monitor Style submenu presents five options governing how you want to monitor inputs while recording.

- **Input:** You only hear the live signal being input; you never hear the contents of tracks.
- **Auto:** When one or more tracks are armed for recording, you hear the live input signal; on playback you hear the contents of each track.
- **Record:** You only hear the live input signal while actively recording, meaning the Record button has been pressed while one or more tracks are armed for recording. You don't hear the input signal while tracks are merely armed.
- **Mute:** You hear nothing.
- **Repro:** While recording, you only hear what's just been recorded, played from the track. In other words, you're not listening to the live input, but you're reviewing what's just been recorded as it's recording.

Recording Using the Onscreen Controls

You can record anywhere you want on the currently armed track or tracks by placing the playhead where you want recording to begin. In this way, you can record to specific areas of your program as you record voiceover, sound effects, foley, or other timed performances that need to fit into a particular region of the edit.

To begin recording:

1. Position the playhead where you want recording to begin.
2. Click the Record button in the transport controls. Recording immediately begins, and the material being recorded immediately begins drawing a waveform in real time, giving you immediate feedback that the input you're recording is properly connected or not, as well as where on the currently armed track material is being recorded.

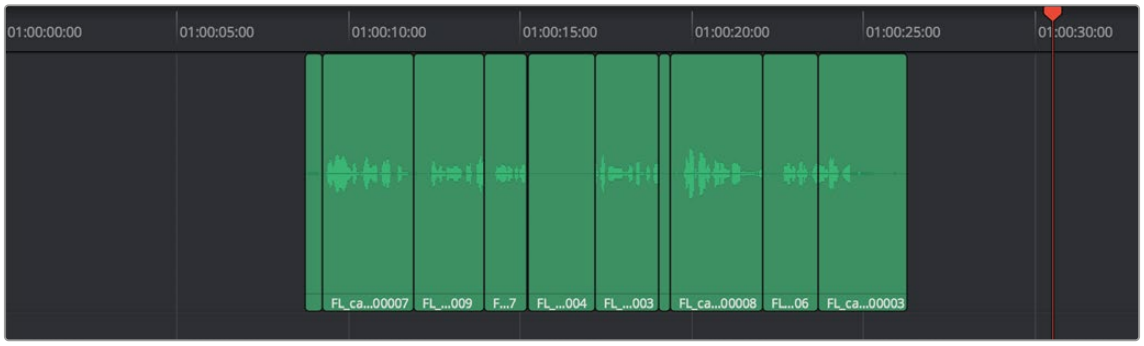
To stop recording, do one of the following:

- Click the Stop button in the transport controls.
- Press the Spacebar.

Recording and Editing Multiple Takes Using Layering

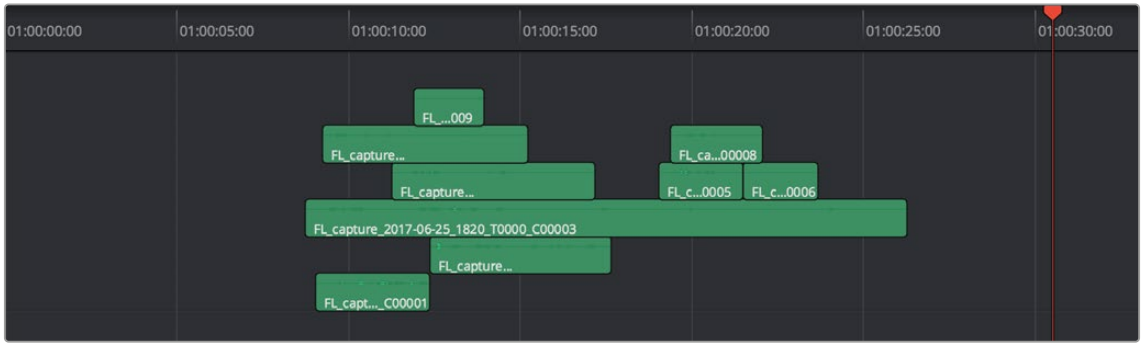
There are two ways you can record multiple takes. You can either record them one after the other, sequentially, and then edit them later. However, you also have the ability to record multiple takes to the same region of the timeline, one on top of another, while at the same time preserving every take using track layering.

In the following screenshot, multiple takes have been recorded over the same section of the timeline, including some partial takes to correct specific phrases in the voiceover being recorded. When you do this, the result looks like a series of cuts and overwritten clips, with the most recently recorded segments being the ones that play back over the previously recorded segments.



Overlapping recordings with Audio Track Layers turned off

However, if you choose View > Audio Track Layers, you'll see that all your recordings have actually been preserved via a vertical stack of overlapping audio clips.



Overlapping recordings with Audio Track Layers turned on, showing layering within the same track

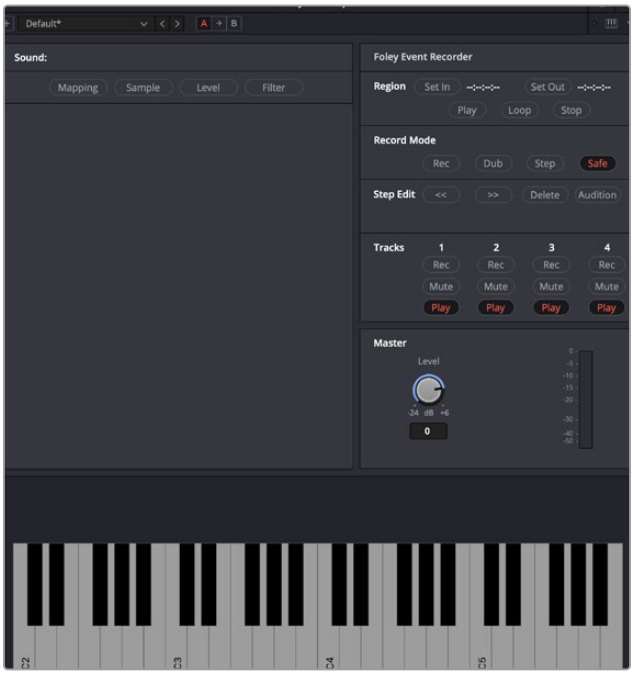
The layering of audio clips in DaVinci Resolve means that the topmost superimposed clips in a layered stack like this mutes the audio of overlapping clips that are lower in the stack.

Using layering, it's easy to edit the best segments of the best takes, while preserving all other takes, simply by adding edits and rearranging clips in the stack so the best parts are on top.

For more information about audio layering, *see Chapter 172, "Editing Basics in the Fairlight Page."*

Recording VSTi Instruments

DaVinci Resolve supports VSTi instruments working with connected MIDI controllers to trigger instrument sounds that can be recorded live on audio tracks of the Timeline. DaVinci Resolve Studio includes the Fairlight FX Foley Sampler. This can be loaded with foley sounds such as footsteps or human movements, so you can perform these sounds in real time and record the result to another track as you watch performers walking or punching in the edit, even if you lack a recording booth with foley pits and props.



The Foley Sampler ready to be filled with sounds

For more information about the Foley Sampler, *see Chapter 178, "Fairlight FX."*

On the other hand, if you're a musician, there's nothing stopping you from loading VSTi musical instruments of different kinds for playback, and using the Fairlight page as a multi-track recorder. DaVinci Resolve doesn't have MIDI sequencing functionality, but you can record live playback straight to the Timeline, using layered audio to manage multiple takes for later re-editing. Bet you never thought you'd be recording music in DaVinci Resolve.

A VST Instrument (in this case Serato Sample) loaded into a track of the Timeline

To enable a MIDI controller in macOS:

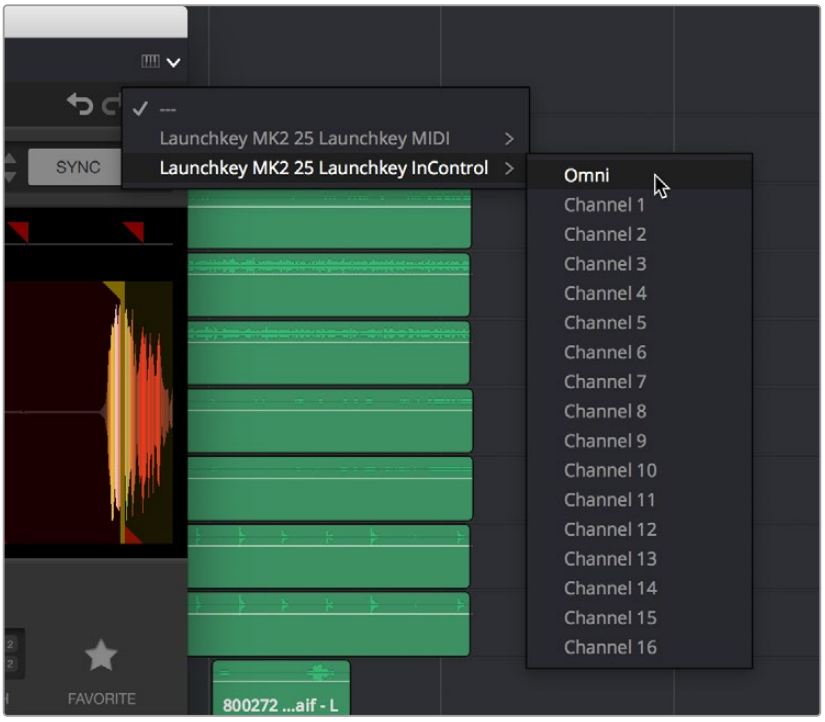
1. If DaVinci Resolve is running, quit before connecting your MIDI controller and setting it up.
2. On macOS you'll use the Audio Midi Setup utility to choose output hardware and select a speaker configuration to be made available on your system. In the Finder, use Spotlight and search for Audio MIDI Setup to open it.
3. In Audio MIDI Setup, choose Window > Show MIDI Studio. A window showing icons for all connected MIDI controllers appears. Your controller should be showing an icon. If it's not, you may need to install drivers for it.
4. Select the icon for your controller and turn on the "Enter test MIDI setup mode" button (it looks like a little keyboard) to test if your keyboard is connecting with the computer. If it is, then turn this off.

For more information on setting up MIDI on different systems, see the DaVinci Resolve Configuration Guide, available on the web from the Blackmagic Design support page at https://www.blackmagicdesign.com/support/family/davinci-resolve-and-fusion.

To set up the Fairlight page for VSTi instrument recording using a sampler:

1. Open DaVinci Resolve.
2. Make sure you have at least two available audio tracks in the Timeline, one for the instrument you'll be playing, and one to record into. This example will use tracks A4 and A5 for this.
3. Open the Effects Library, find a VSTi sampler you have installed on your system, and drag it to the track header of the track you want to use for playing, for example track A4.

   Massively-featured sampler/synth combinations such as Native Instruments Kontakt and Steinberg Halion are ubiquitous and useful when you want to specifically map a collection of sound effects to specific keys or pads to create re-usable multi-purpose instruments. However, more streamlined samplers that emphasize automatic audio clip slicing such as Serato Sample (Windows and macOS) or Image Line Slicex (Windows only) can make short work of the more specialized task of loading library sound effects recordings (or custom recordings you create) with multiple footsteps, punches, keyboard presses, cloth rustles, or other foley activities, and quickly splitting them up into individually playable samples you can trigger with pads or a keyboard.
4. When the VSTi interface window appears, open the MIDI menu at the upper right-hand corner of the VSTi window and choose the correct MIDI channel from your MIDI controller's submenu. If you've selected the correct MIDI channel, the instrument should start responding to the keys or pads on your controller.



Enabling MIDI control

5. Next, configure the VSTi instrument you're using to play the sound effects you want to use for foley. In this example, the Serato Sample VSTi plugin is being used to automatically slice up a recording of footsteps from one of Sound Ideas' many sound effects libraries.

   Because the VSTi you added is patched to that track's Insert (if you look at the Mixer you should see that the I button is enabled on the channel strip the instrument is patched to), the Send is PRE the Instrument. This means you need to patch that track's Track Direct output to the input of another track to record the instrument.

6 Choose Fairlight > Patch Input/Output to open the Patch Input/Output window, then set the Source dropdown menu to Track Direct and the Destination dropdown menu to Track Input. Click Audio 4 to the left, and Audio 5 to the right, and click the Patch button; this sets you up to play the VSTi plugin on track A4, and record its output on track A5.

   Be aware that after patching Track Direct from the track with the instrument to the track you're recording onto, you also need to turn "Direct Output" on for that track in the Path Settings of that track's channel strip in the Mixer.

7 Open the Mixer (if necessary), click the Input dropdown menu at the top of the channel strip that shows the VSTi instrument you're using, and choose Path Settings. When the Path Settings window appears, click the ON button for Direct Output, then close the Path Settings window.

At this point, you're ready to begin recording.

To play and record a VSTi instrument:

1 Click the Record Arming button of the track you're recording to (in this example A5), move the playhead to where you want to begin recording, and then click the Record button to begin recording.

2 As the video of your program plays, use your MIDI controller to trigger sound effects as necessary. When you're finished, click the Stop button.

   If necessary, you can record multiple takes using track layering until you get the timing right. When you're finished, you can remove the instrument from the track it's on since the recorded audio is all you need.

Chapter 171

ADR (Automated Dialog Replacement)

The Fairlight page of DaVinci Resolve has a sophisticated interface for doing ADR, or automated dialog replacement, in a structured and straightforward manner.

Simple, yet powerful, the ADR panel incorporates Cue list management, industry-standard audio beeps and visual cues, and sophisticated take management with star ratings and layered take organization to create and manage the re-recording of dialog in any program. With this sophisticated organization and layering, it's easy to edit together the best parts of each take into your program.

Contents

ADR (Automated Dialog Replacement) 3602

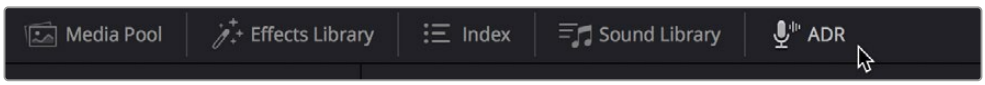
Creating and Importing ADR Cue Lists 3607
Manually Creating an ADR Cue List 3607
Importing Cues 3608
Recording ADR to the Timeline 3609

ADR (Automated Dialog Replacement)

Clicking the ADR button on the Interface toolbar opens the Fairlight ADR panel, which offers a thoroughly professional automated dialog replacement workflow. Dialog replacement, for those who don't know, is the process whereby audio professionals bring in actors to re-record unusable dialog recordings from the comfort of their recording studios, line by line and with a great deal of patience.



The ADR panel on the Fairlight page

It's an old joke that ADR isn't really automatic, but the Fairlight page aims to help you make this a structured and straightforward process. Simple, but powerful, Cue list management lets you efficiently assemble a re-recording plan.

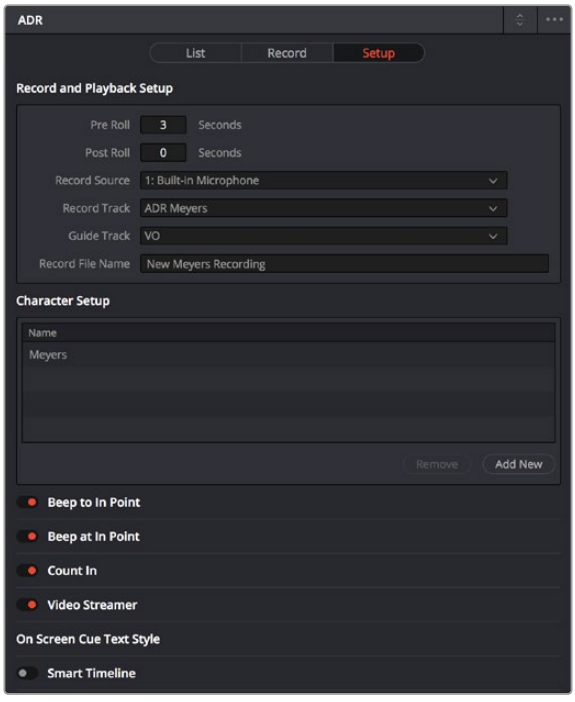
Industry-standard audio beeps and visual cues via your BMD video output device help the actors in the booth nail their timings and their lines. Then, sophisticated take management with star ratings and layered take organization in the Timeline help you manage the resulting recordings to pick and choose the best parts of each take when you edit the results.

The ADR Interface

The ADR interface consists of three panels to the left of the Timeline: a List panel, a Record panel, and a Setup panel. The controls of these panels are described in the order in which they're used..

The Setup Panel

As its name implies, the Setup panel is where you configure your ADR session.



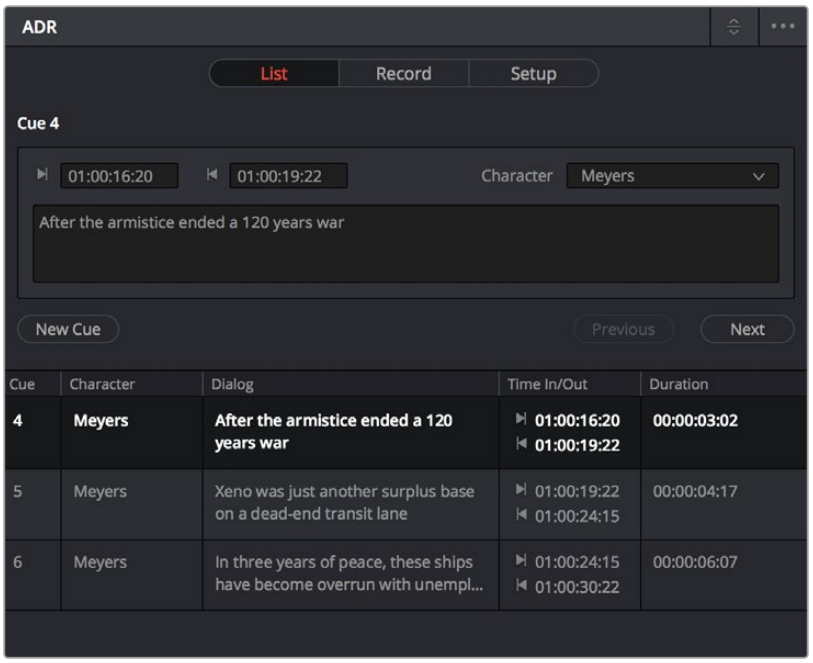
The Setup panel of the ADR interface

This panel presents the following controls:

- **Pre Roll and Post Roll:** Specifies how many seconds to play before and after each cue's specified In and Out points, giving actors a chance to listen to what comes before and after each cue in order to prepare. If you enable the Beep options below, they'll provide a countdown during the specified pre-roll.
- **Record Source:** This dropdown menu lets you choose the audio input you want to record from, creating a patch to the Record Track. However, this menu is disabled until you select a track in the Record Track dropdown menu.
- **Record Track:** This menu lets you choose the track you want to record on. Making this selection creates a patch from the Record Source to the Record Track and automatically toggles Record Enable on.
- **Guide Track:** This dropdown lets you choose the track containing the production audio you want to re-record. The talent will use the audio playback from this track as a guide when recording their replacement performance.
- **Record File Name:** This text field lets you enter a filename for the recorded audio.
- **Character Setup:** This is where you can add the character names you'll be re-recording, which helps with cue creation and management. Click the Add button to enter a new character name. To delete a character from the list, click the character name and then the Remove button.
- **Beep to In Point:** Enables a three-beep sequence, which the talent hears leading up to the recording. For the beeps to be audible, the Beeps channel of the System Generator must be patched to your audio outputs by going to Fairlight > Patch Input/Output.
- **Beep at In Point:** Enables one last beep at the In point. For the beep to be audible, the Beeps channel of the System Generator must be patched to your audio outputs by going to Fairlight > Patch Input/Output.
- **Count In:** Provides an onscreen counter that counts down to the start of the cue.
- **Video Streamer:** A visual cue for the talent to watch during pre-roll to ready them for recording. A pair of vertical lines superimposed over the program being output to video move towards one another across your video output screen during the pre-roll to the cue. This gives the talent a visual indication of the time remaining until they should begin talking. When the beeps play, these lines get taller. Both lines come together at the Time In frame, at which point a cross shows that recording is beginning.
- **On Screen Cue Text Style:** Clicking this heading reveals a set of parameters for configuring the look and placement of onscreen text cues.
- **Smart Timeline:** When turned on, this option automatically moves the playhead to each cue as it's selected in the Cue list, and zooms in to frame the duration of that cue in the Timeline.
- **Mixing Control:** Enables automated switching of audio playback, to independently control what the talent and the audio engineer hear at various stages of the ADR recording process. For example, with this enabled, the Guide track is not routed to the Control room while the engineer is reviewing a take.

The List Panel

This is where you create a list of cues you need to re-record, either from within the Fairlight page or imported from a .csv file.



The List panel of the ADR interface

This panel includes the following controls:

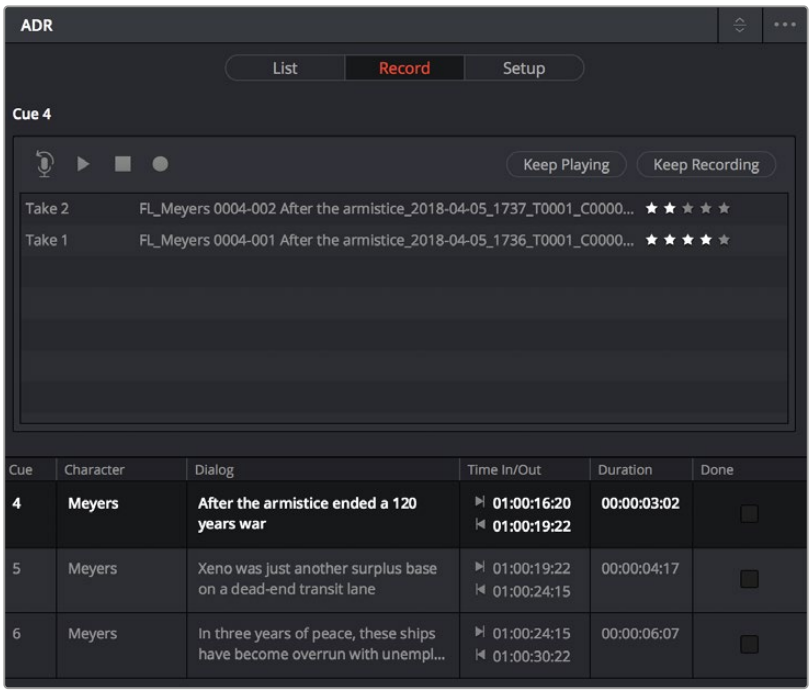
- **Cue editing controls:** Displays the data for the currently selected cue (or a cue that was just created). In and Out timecode fields store the Timeline In and Out points that were set when the cue was created but can be manually edited for fine tuning. A Character dropdown menu lets you choose which character that line of dialog belongs to. A text entry field lets you enter the dialog cue that's to be re-recorded, so you and the talent can both refer to it.
- **New Cue button:** Clicking this button adds a new cue to the list using whatever In and Out points have been set in the Timeline, and whatever character was last selected.
- **Cue list:** The list of all cues that have been entered or imported. The Cue list can be filtered using the Filter dropdown menu at the top-right of the ADR panel (next to the option menu). You can choose to show the cues for all characters, or for any selected combination of characters. You can also choose to hide all cues that are marked as done to experience the joy of this list shrinking more and more the closer you are to being finished.

Additionally, the ADR interface option menu has three commands pertaining to the List panel:

- **Import Cue List:** Lets you import a properly formatted .csv file to create cues that have been prepared in a spreadsheet. Correct formatting for cue lists you want to import is no headers, one line per cue, with four individual columns for In timecode, Out timecode, Character Name, and Dialog.
- **Export Cue List:** Lets you export the contents of the Cue list to a .csv file, for exchange or safe-keeping.
- **Clear Cue List:** Deletes all cues in the Cue list. It's recommended you export a copy of your Cue list before eliminating it completely, in case you ever need to revisit a cue.

The Record Panel

This is where you actually run the ADR recording session you've set up, using the dialog cues you've put into the Cue list.



The Record panel of the ADR Interface

This panel presents the following controls:

- **Record and rehearse controls:** Four transport controls and two buttons let you control recording during ADR sessions. These controls are only clickable when you've selected a cue from the Cue list to record.

  Rehearse: Runs the section of the Timeline specified by a cue without actually recording anything, giving the talent an opportunity to run through their dialog and practice their timing and delivery. Beeps and on-screen streamers are not played during a rehearsal.

  Play: Plays the currently selected take from the Take list (described below). If no take is selected, the most recently recorded one on top is played.

  Stop: Immediately stops rehearsal, playback, or recording.

  Record: Initiates recording of the cue to the specified audio track, with cue beeps and video streamer cues.

  Keep Playing: At the end of a take you may wish to keep playing, so the talent can hear the next section of the track. Pressing the Keep Playing button at any time, even while recording, results in post roll being ignored and normal playback resuming after the cue's Out time.

  Keep Recording: At the end of a take you may wish to keep recording until you manually stop. Pressing the Keep Recording button at any time, even while recording, results in the Out point of the current cue being ignored and recording continuing until you stop it.

- **Take list:** The Take list shows every take you've recorded for the current cue, with take number, name, and a five-star rating that you can set to keep track of which takes worked and which didn't. Earlier takes are at the bottom of this list, while recent takes are at the top (the same order in which the corresponding layered audio clips appear in the Timeline track they've been recorded to).

- **Cue list:** The list of all cues that have been entered or imported. The Cue list can be filtered using the Filter dropdown menu at the top-right of the ADR panel (next to the Option menu). You can choose to show the cues for all characters, or for any selected combination of characters. You can also choose to hide all cues that are marked as done to experience the joy of this list shrinking more and more the closer you are to being finished.
- **Cue list Done column:** A sixth column appears in the Record panel only, labeled Done. It contains check boxes for each cue that you can turn on to keep track of which cues you've successfully finished.

Additionally, the ADR interface Option menu has one command pertaining to the Record panel:

- **Record Early In:** Enables recording during pre-roll, in the event you're working with talent that likes to start early.

Setting up to Do an ADR Session

Setting up to record ADR is straightforward but requires a few steps.

Creating tracks in preparation to record ADR:

1. In the Timeline, create a new audio track to which you'll be doing ADR recording. Make sure it has the correct channel configuration for your recording (mono is typical for dialog).
2. If you're recording ADR to your main timeline, you may want to Solo both the Guide track and the Record track, so you and the talent can focus on the audio being re-recorded without hearing all the other tracks of the current mix.

   Now you're ready to configure the Setup panel.

Configuring the Setup panel:

1. Open the ADR interface, and then open the Setup panel.
2. Choose the Pre Roll and Post Roll you want to use, in seconds. A pre roll of at least 3 seconds is recommended to give the talent time to get ready.
3. From the Record Source dropdown menu, choose the microphone you patched earlier.
4. From the Record Track dropdown menu, choose the Record track you created.
5. From the Guide Track dropdown menu, choose the track with the original production audio that you're replacing.
6. At the bottom of this panel, turn on which Preroll Cue options you and the talent want to use as you record each cue. Options include:

   a) Beep to In Point and Beep at In Point provide an audible count down to when to start performing.

   b) An animated Video Streamer gives a countdown to the start time, shows the duration of the cue being recorded, and also displays the text of the dialog for that cue on screen for the actor to refer to, so they can keep their eyes on the screen and not a script.

Next, if you've enabled Beep to In Point and Beep at In Point, you need to patch the Fairlight oscillator to your output channels so the talent can hear the preview beeps.

Patching the Oscillator to play beeps over your audio output:

1. Choose Fairlight > Patch Input/Output to open the Patch Input/Output window.
2. Choose System Generator from the Source dropdown menu, and click to select Beeps.
3. Choose Audio Outputs from the Destination dropdown, and choose the left/right outputs you want these preview beeps to play out of. You can drag a bounding box to select multiple outputs, thereby connecting the mono Beeps input to stereo output for comfortable listening.
4. Click Patch to make the connection, then close the Patch Input/Output window.

Creating and Importing ADR Cue Lists

You must have a list of cues to be able to use the ADR interface properly. There are two ways you can create a Cue list to record with, make one from scratch on the Fairlight page, or import one. The ADR panel accommodates both workflows.

Manually Creating an ADR Cue List

If you've been doing all of your dialog editing inside of DaVinci Resolve, you can go ahead and create a list by marking the sections of the Timeline you need to re-record and creating cues from those timings. To create cues properly, you should start by adding the names of each character you'll be creating a cue for in the Setup panel. These names make it easier to enter cues and will help you to filter and sort the list as necessary later on.

To add character names before entering cues:

1. Open the Setup panel of the ADR interface.
2. Click Add New.
3. When a selected entry appears in the Character Setup list, type a name.
4. Press Return when you're done.

To edit the Character Setup list, do one of the following:

- If you mis-spell a name, you can double-click any name in this list to edit it.
- To delete a name, you can select it and click Remove to eliminate it.

Once you've created a complete set of character names, you can begin creating your Cue list.

To manually add cues to the Cue list:

1. Open the List panel of the ADR interface. This is where all the controls for creating and editing cues are.
2. In the Timeline, set In and Out points to mark the section of dialog you want to turn into a cue. Those timecode values appear in the Cue Editing section of the List panel.
3. Click New Cue to add a blank cue to the Cue list.
4. In the Cue Editing section, choose the character who's speaking that cue from the Character dropdown (only names that have been entered in the Setup tab appear in this list).
5. If necessary, select the text field below, and type the dialog that needs to be re-recorded.
6. Repeat steps 2 through 5 until you're finished creating all the cues you intend to re-record. If you need to edit any cue, simply click to select that cue, and edit it in the Cue Editing section above.

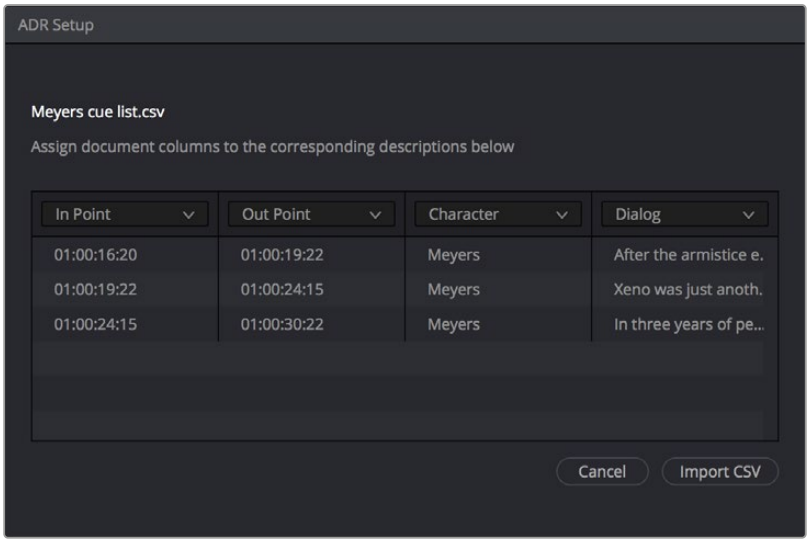
Importing Cues

If you or an assistant has already created a Cue list using a spreadsheet with separate columns for character names, dialog, and In/Out timecode values, then you can also create a Cue list by importing this data from an exported .csv file.

To import a .csv file to the Cue list:

1. Choose Import Cue List from the ADR option menu, then use the dialog to choose the .csv file containing the Cue list you were given, and click Open.
2. An ADR Setup dialog appears, showing the data from the .csv file previewed as a series of columns. This lets you see if each column of incoming data is being assigned correctly. If it's not, you can reassign each column of the incoming data to the correct column of the ADR panel.

   Correct formatting for Cue lists you want to import is to have no header text, and to enter information using one row per cue, with four individual columns for In timecode, Out timecode, Character Name, and Dialog. If any of these columns are transposed, you can correct this by choosing the correct data type for each column from the dropdown menus at top.



Dialog for rearranging columns of cue data, if necessary

3. Click Import CSV. The cues should appear in the Cue list.

To export a .csv file from the Cue list:

- Choose Export Cue List from the ADR option menu, choose a location to save the file, and click Save.
-

Recording ADR to the Timeline

Once you've configured your workstation for recording, and you've set up a Cue list to work with, it's time to start recording each cue.

To record a cue from the Cue list:

1. Open the Record panel of the ADR interface.
2. If you want to record a particular character's cues, you can select each unnecessary character in the ADR Option menu to uncheck that character, hiding their dialog in the Cue list.
3. With the list showing the character cues you need, select the cue you want to start recording. That cue contains the timecode necessary to determine which part of the Timeline to record to, and the playhead automatically moves to that part of the Timeline.
4. Click the Rehearse button a few times to run through the cue with the talent. When you click Rehearse, both audio and video corresponding to that cue will play, including pre roll and post roll, along with all beep and onscreen cues.
5. When the talent is ready to try a take, click the Record button, and let the Fairlight page do the work of playing through pre roll with beep notifications and visual streamer cues, initiating recording, and then stopping recording automatically once the cue is done. To record another take, simply click the Record button again.

   Every time you complete a recording, a take appears in the Take list. Making multiple recordings results in multiple takes in the list. In the Timeline, all new takes appear as layered audio, so you can record as many takes as you like into the same area of the Timeline. Once you've finished recording takes, you'll have a neatly organized stack of alternate takes to draw upon as you edit together the best parts of each recording.
6. If you or the talent want to hear a particular take again, select it in the Take list and click Play. You can use the 5-star ratings control to keep track of how you liked each take.
7. When you're finished recording a cue, click the Done checkbox for that cue, and select the next cue you want to record. When you're finished re-recording dialog, simply close the ADR interface.

Chapter 172

Editing Basics in the Fairlight Page

You can use the Fairlight page to refine the editing of audio that was initially assembled in the Edit page, or you can use the Fairlight page to both record and edit audio programs from scratch.

Because audio clips have properties that video clips do not, audio editing encompasses additional procedures that are not available in the Edit page. This chapter takes you through the fundamental steps of editing audio the Fairlight way.

Compatible Audio Formats

DaVinci Resolve is compatible with WAVE, Broadcast WAVE, AIFF, MP3, AAC (M4A), CAF (macOS only), both MTS and QuickTime containers that use the AC3 audio format, and Enhanced AC-3 (macOS and Windows only). DaVinci Resolve is compatible with audio at sample rates including 32, 44.1, 48, 88.2, 96, and 192 kHz. Linux users have the added ability to encode and decode MP3 files in Fairlight.

DaVinci Resolve 17 adds Dolby Atmos ADM file creation and manipulation as well as the ability to export Dolby Atmos masters as IMF deliverables. IMF (Interoperable Master Format) is a SMPTE standard for a single master file format that incorporates all the media and metadata necessary to deliver what's necessary.

ADM Import

Importing an ADM file into a project will open the Bed mix or mixes and any associated Object tracks into a timeline. They will be imported onto corresponding track types of the audio files embedded into the ADM. For instance, if a Bed file is 7.1.2, then on import that file will open in a 7.1.2 track in Fairlight. Object files will be created as separate tracks in Fairlight containing all of their panning data.

NOTE: If bringing in a Dolby Atmos file from the Media Pool, it will render the file dynamically to the chosen output format directly on the Timeline using the Dolby Renderer. However, Fairlight can import the full Atmos file with beds and objects if imported from the Fairlight menu instead - Fairlight > Immersive > Audio > Import Master File. By bringing a file in this way, it will create a timeline with all of that file's Atmos program and dynamic metadata properly mapped and routed.

Editing Audio Clips Into the Timeline

The Fairlight page offers a complete audio editing environment that lets you either record and assemble clips from scratch, or refine tracks full of audio clips that have been edited together in different ways. There are four ways of adding media to the Timeline in the Fairlight page, depending on the type of work you do:

- Recording new audio into one or more tracks,.

  For more information, *see Chapter 170, "Recording."*

- By dragging and dropping new audio clips from the Media Pool into the Fairlight timeline
- By editing audio clips into audio tracks on the Edit page
- By importing a project with audio clips
- By auditioning and confirming sound effects from the Sound Library

However audio clips come to be in your timeline, the rest of this chapter covers the myriad methods available to edit and sweeten the contents.

Overwriting Vs. Layering Clips That Overlap

When you add clips to the Timeline, what happens when you add a clip that overlaps another clip that's already in the track you're editing to depends on the Timeline > Layered Audio Editing setting. By default, with Layered Audio Editing turned off, overwriting one audio clip with another results in the overlapping part of the overwritten clip being non-destructively deleted from the Timeline by the incoming clip.

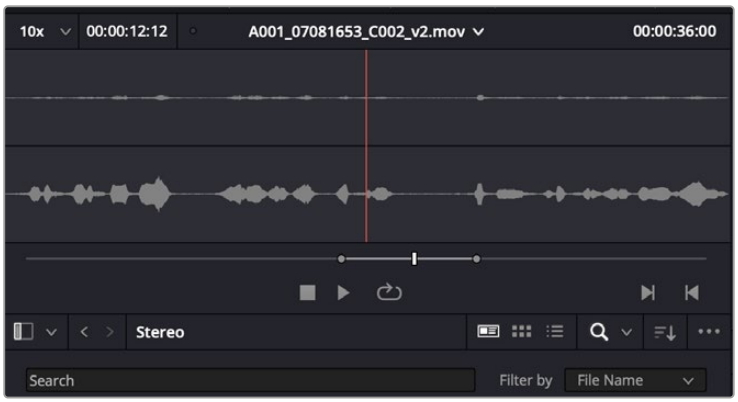
However, if you turn Layered Audio Editing on, then incoming clips do not overwrite overlapping clips in the Timeline; instead, they're layered within that track, such that the incoming audio clip takes precedence over what was previously there, but overlapping audio segments that were previously in the Timeline are preserved, which can be seen when you choose View > Show Audio Track Layers.

In this way, you can choose whether you want to overwrite previously edited clips, or layer newly edited clips, as your needs require, regardless of whether or not Audio Track Layers are visible. Audio layering can be enabled in both the Edit and Fairlight pages.

For more information about audio layering, see the section later in this chapter.

Choosing Parts of Clips to Edit in the Media Pool

The Media Pool has a preview player at the top that provides a place to open selected source clips in the Media Pool, play them, add marks to log them, and set In and Out points in preparation for editing them into the Timeline via drag and drop. The Media Pool Preview Player effectively acts as a Source monitor for editing in the Fairlight page.



The preview player in the Media Pool

- Various viewing controls populate the title bar at the top. A dropdown menu at the upper left lets you choose a zoom level for the audio waveform that's displayed. To the right of that, a Timecode window shows you the duration of the clip or the duration that's marked with In and Out points. Next to the right, a real-time performance indicator shows you playback performance. In the center the title of the currently selected clip is shown, with a dropdown menu to the right that shows you the most recent 10 clips you've browsed. To the far left, a Timecode field shows you the current position of the playhead (right-clicking this opens a contextual menu with options to change the timecode that's displayed, and to copy and paste timecode).
- The center of the Media Pool Preview Player shows you the waveforms in all channels of the currently selected clip, at whatever zoom level is currently selected.
- Transport controls at the bottom consist of a jog bar for scrubbing, Stop, Play, and Loop buttons, and In and Out buttons.

Dragging Audio Clips Into the Timeline

You can show the Media Pool in the Fairlight page, and edit audio clips into the Timeline in their entirety by dragging and dropping individual clips onto whichever audio track you want them to appear. You can drag any clip onto any track, regardless of whether or not the channels of the clip match the channel mapping of the track. However, if you edit a clip with more channels than a track has (for example, editing a stereo clip onto a mono track), only the channels supported by that track will be output, with all other channels in that clip being muted. If this happens, you can always remap the audio track by right-clicking the track header and choosing a new mapping from the Change Track Type To submenu.

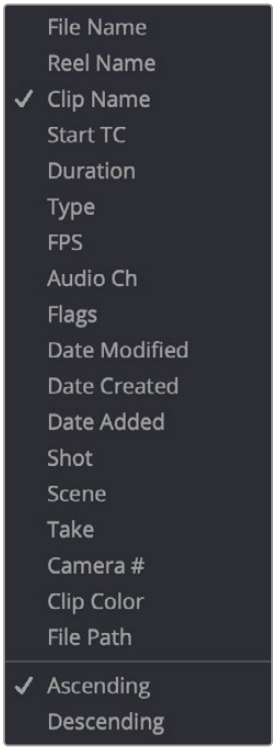
TIP: Dragging one or more clips to the empty area underneath the existing audio tracks of the Timeline results in the creation of new tracks, each of which is automatically mapped to however many channels are required by each audio clip being edited.

When working with Ambisonics files, dragging a clip to the timeline or creating a new timeline that refers to a clip creates a track of the appropriate type, matching the file's Ambisonic order and channels.

If you want to edit several clips into the Timeline at once by dragging them from the Media Pool, you'll probably want to do a bit of preparation to make sure they're edited in the right order.

Dragging several clips into the Timeline as one contiguous series of edited clips:

1 Change the sort order of the Media Pool's browser area to put the clips into the order in which you want them to appear. In Thumbnail view you can use the Sort Order menu, but in List view you can click the header of any metadata column to sort by that column's data.



Using the Sort Order menu to change the sort order of clips in the Media Pool

2 Use the Media Pool thumbnails, the Media Pool List view Filmstrip, or the Source Viewer to set In and Out points to define the part of each clip that you want to edit into the Timeline.

3 Select the Media Pool clips you want to edit into the Timeline by dragging a bounding box, Command-dragging multiple bounding boxes over different sets of clips, by Shift-clicking a range of clips, or by Command-clicking individual non-contiguous clips.

4 Drag any of the selected clips to the desired position in the Timeline to perform an overwrite edit.

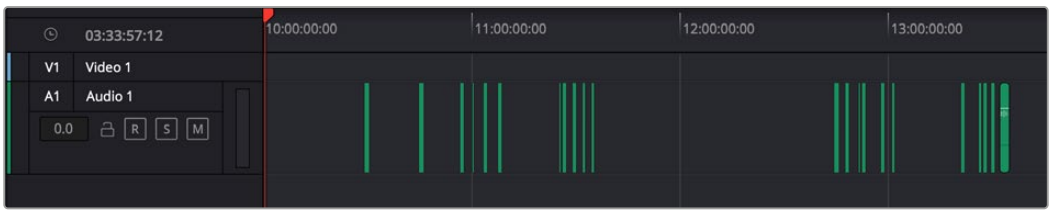
The clip(s) you drag overwrite whatever other clips they overlap in the Timeline. Multiple clips dragged from the Media Pool will be edited in the order in which they're sorted in the Media Pool, using each clip's In and Out points.

It's possible to edit audio clips into the Timeline so that each clip's timecode lines up with the Timeline Ruler. This can be useful if you're organizing multiple source audio recordings that you want to synchronize together on multiple tracks.

Dragging multiple clips to edit them into a track at their timecode positions:

1 Select the Media Pool clips you want to edit into the Timeline by dragging a bounding box, Command-dragging multiple bounding boxes over different sets of clips, by Shift-clicking a range of clips, or by Command-clicking individual non-contiguous clips.

2 Hold Command-Shift down, and drag the selected clips into the track you want them to appear, to perform an overwrite edit.



A series of audio clips edited into the Timeline by timecode position

Each clip edited into that track appears at the same timecode position as its embedded timecode. This means that if you were recording time-of-day timecode, each clip will appear on the Timeline at the time it was recorded. A series of clips recorded during hour 10 through 13 will appear distributed throughout hours 10-13 on your timeline.

You can also edit two or more audio clips into the Timeline as a stack, in preparation for layering multiple sound effects for doing sound design work.

Dragging multiple clips to edit them into a track as a parallel stack:

1 Select the Media Pool clips you want to edit into the Timeline by dragging a bounding box, Command-dragging multiple bounding boxes over different sets of clips, by Shift-clicking a range of clips, or by Command-clicking individual non-contiguous clips.

2 Command-drag the selected clips into a track of the Timeline. The first of the selected clips appears in the track you're dragging to, the other clips appear either in audio tracks underneath the first one, or if there are no audio tracks available, in new audio tracks that will be created to hold those clips.

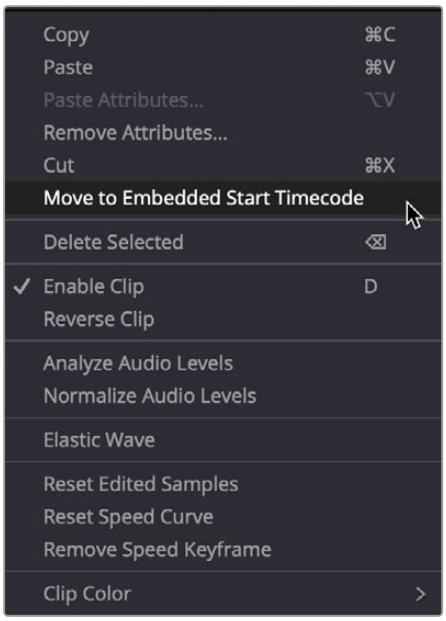
All clips you've edited appear as a parallel stack, in separate tracks, one on top of another.

Moving Audio Clips to Embedded Timecode Position

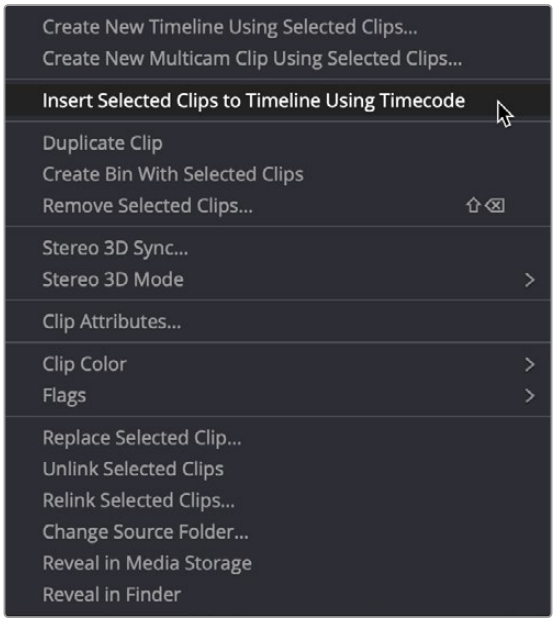
All clips have a timecode embedded into their metadata. There are options to place clips onto the Timeline from either the Media Pool or in the Timeline itself with this metadata.

Right-clicking a clip in the Timeline has the choice to Move to Embedded Start Timecode. When this is clicked the clip will spot onto the Timeline on a selected track with the timecode.

It's important to be aware of the embedded audio timecode and the Timeline timecode. The two must have overlapping timecode, or this function will not work. For example, a clip that has an embedded timecode of 00:00:00:00 may be difficult to find on a Timeline that starts at 00:59:58:00. If you have spotted a clip using these tools and still don't see the clip in question, then check the embedded timecode in the Metadata panel of the Inspector as well as the timecode of the Timeline itself.



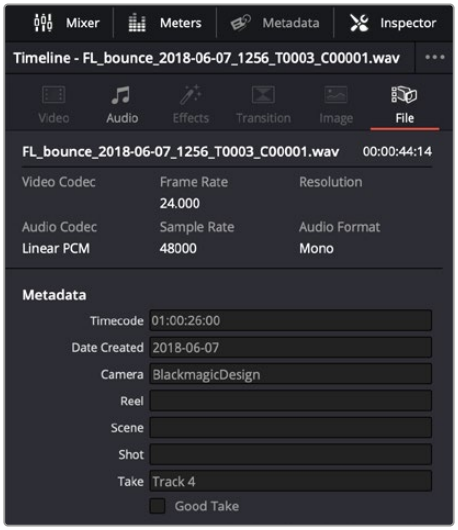
Right-clicking a clip in a Timeline reveals the Move to Embedded Start Timecode option.



Right-clicking a clip in the Media Pool reveals the Insert Selected Clips to Timeline option.

Right-clicking a clip in the Media Pool has the choice to Insert Selected Clips to Timeline Using Timecode. When this is clicked the clip will spot onto the Timeline on a selected track with the embedded timecode.

NOTE: You can find the embedded timecode for a clip in the Inspector in the File tab under timecode.

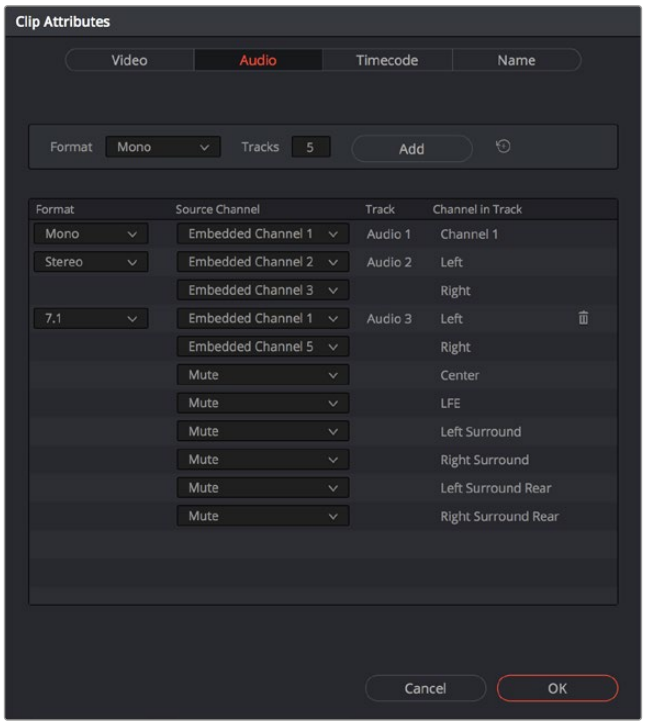


Timecode metadata is in the Inspector window under the File tab.

Support for Mixed Audio Track Formats from Source Clips

DaVinci Resolve supports media with multiple audio tracks that have differently formatted channels embedded within them. For example, a clip with one stereo track, one 5.1 surround track, and six mono tracks can all be appropriately set up in the Audio panel of Clip Attributes after that clip has been imported.

The Audio panel of Clip Attributes has controls over what format (Mono, Stereo, 5.1, 7.1, Adaptive) the channels embedded within a particular audio track should be configured as. This means you can set up clips with multiple tracks, each one using different formats of audio employing different combinations of channels, which is useful for setting up imported audio mix files that you want to output when mastering a program.



Clip Attributes now lets you assign channels among different tracks with different channel assignments

Making Audio Clip Selections in the Timeline

Nearly every editing operation described in this chapter and others requires you to make a selection to define which clips will be affected. Three editing modes in the toolbar give you different ways of selecting clips, depending on what you're trying to do, and how you like to work. These are (from left to right) the Pointer mode, the Range mode, and the Focus mode. Which mode you choose determines how clips and clip segments are selected in the Timeline in preparation for all manner of editorial operations.

The Pointer, Range, and Focus modes seen in the toolbar

Fairlight Edit Mode Remains Between Application Restarts

Fairlight retains the Edit Mode the project was saved with between restarts. Whatever edit mode you were working in prior to closing the application will be active when reopened.

Why Are There Three Edit Modes?

While the Pointer and Range modes can also be used with the pointer, they're really designed to enable automatic selections based on the position of the playhead. This is accomplished when using the Fairlight Editing console, the Fairlight Desktop Console, or keyboard shortcuts to control Timeline transport, while specific tracks are selected to enable selection and editing on those tracks.

The Focus mode is designed for efficient selections made using the pointer via a mouse, trackpad, or pen and tablet, made in conjunction with a variety of commands for extending and editing selections triggered via keyboard shortcuts. If you're editing with a keyboard and mouse, this mode is designed to let you work quickly by enabling a variety of different selection functions based on clicking different parts of clips.

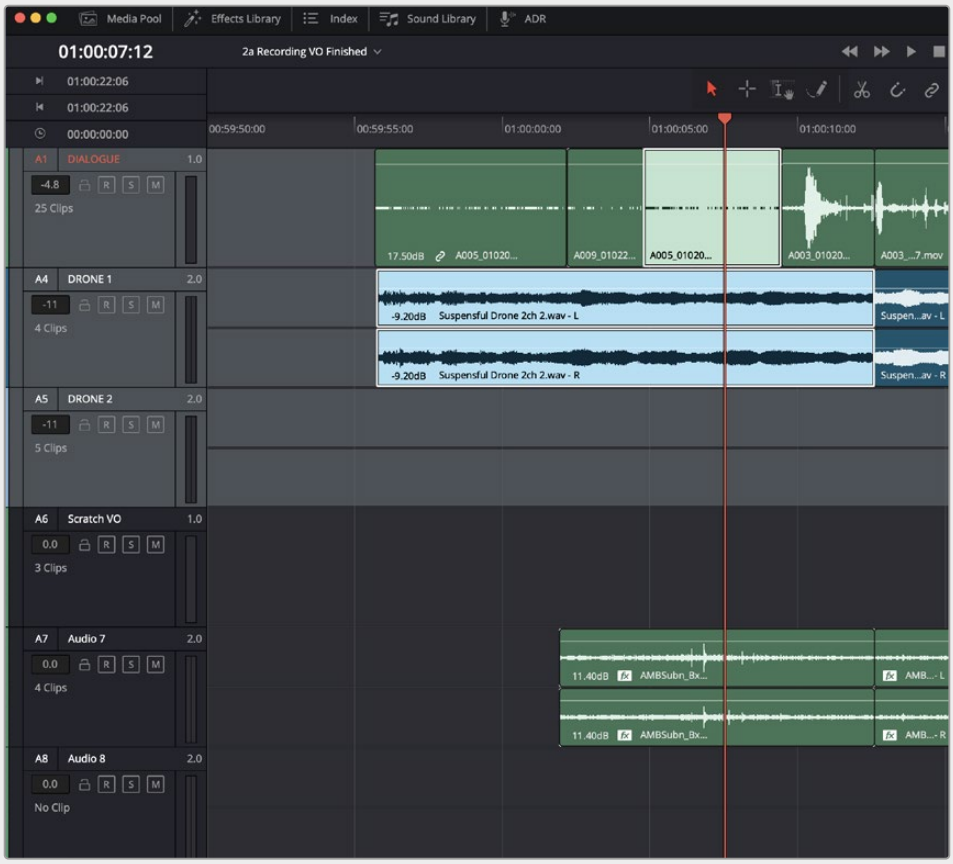
Selecting Tracks

In order to understand clip selection, you must first understand track selection. The Timeline on the Fairlight page lets you select entire tracks to facilitate the automatic selection of clips that intersect the playhead on those tracks using keyboard shortcuts, the Fairlight Desktop Console, or the Fairlight Editing panel, in Pointer and Range modes (described in upcoming sections).

For example, were you to select tracks A2, A3, and A4, then moving the playhead to intersect two clips on those tracks in Pointer mode automatically selects them, so they're ready for any operation you want to perform on both clips. To give a few examples, you could now split both clips at the playhead, Cut Head or Tail to the playhead, Delete both clips, or Copy them in preparation for pasting elsewhere.

Additionally, there are times when clicking or dragging on one or more clips with the pointer results in both those clips being selected, along with the tracks on which they sit. For example, selecting clips using the Focus mode will also select the tracks those clips are on.

If you're manually selecting tracks using the pointer, there are different ways to do so.



Command-clicking multiple track headers selects t.hose tracks

Methods of selecting and deselecting tracks in the Fairlight page Timeline:

- **To select a single track:** Click anywhere in the background or on the track number of that track's header (not on a button). In Range mode you can also click in any unused area of the track itself.
- **To deselect a single track:** Click anywhere in the background or on the track number of a previously selected track's header (not on a button). In Range mode you can also click in any unused area of the track itself. If multiple tracks are selected, Command-clicking one will remove just that track from the selection.
- **To select multiple tracks:** Command-click in the track header background of every track you want to select. In Range mode you can also Command-click in any unused area of the tracks themselves. Command-clicking an already selected track will deselect it.
- **To select multiple continuous tracks:** Click anywhere in the background or on the track number of a track header, and then drag a bounding box up or down over all other tracks you want to select. In Range mode you can also drag a bounding box over any part of the tracks themselves, while also defining a range in which you want to work.
- **To move the selection to higher or lower tracks:** Press Control-Option-Up Arrow or Down Arrow to move the selection state to the next track higher (Control-Option-Up Arrow) or lower (Control-Option-Down Arrow). If multiple tracks are selected, then the multi-selection will be moved as a block; for example, selecting tracks A2 and A3 and then pressing Control-Option-Down Arrow will result in tracks A3 and A4 being selected.

Using Pointer Mode

Pointer mode uses the position of the playhead to make automatic selections when using the Fairlight Editing console or keyboard shortcuts to make clip selections on selected tracks. However, you can also use this mode in conjunction with the pointer and keyboard shortcuts to make selections in a different style. Pointer mode is primarily intended to allow efficient editing of whole clips.

- **If no tracks have been selected:** Clips that intersect the playhead are not selected. You can use the pointer to select one or more clips by clicking, Command-clicking, or dragging a bounding box. Clips you select in this way are highlighted in orange. Making selections in this way is similar to making clip selections in the Timeline of the Edit page.
- **If tracks have been selected:** All clips that intersect the playhead on selected tracks will be automatically highlight selected, but no In and Out points will be set. Clips on de-selected tracks will be ignored. Selecting one or more clips with the pointer (by Command-clicking or dragging a bounding box) creates an orange-highlighted selection.
- **If you set In and Out points:** Some functions will affect ranges of clips between In and Out points on selected tracks. Clips on unselected tracks are ignored.

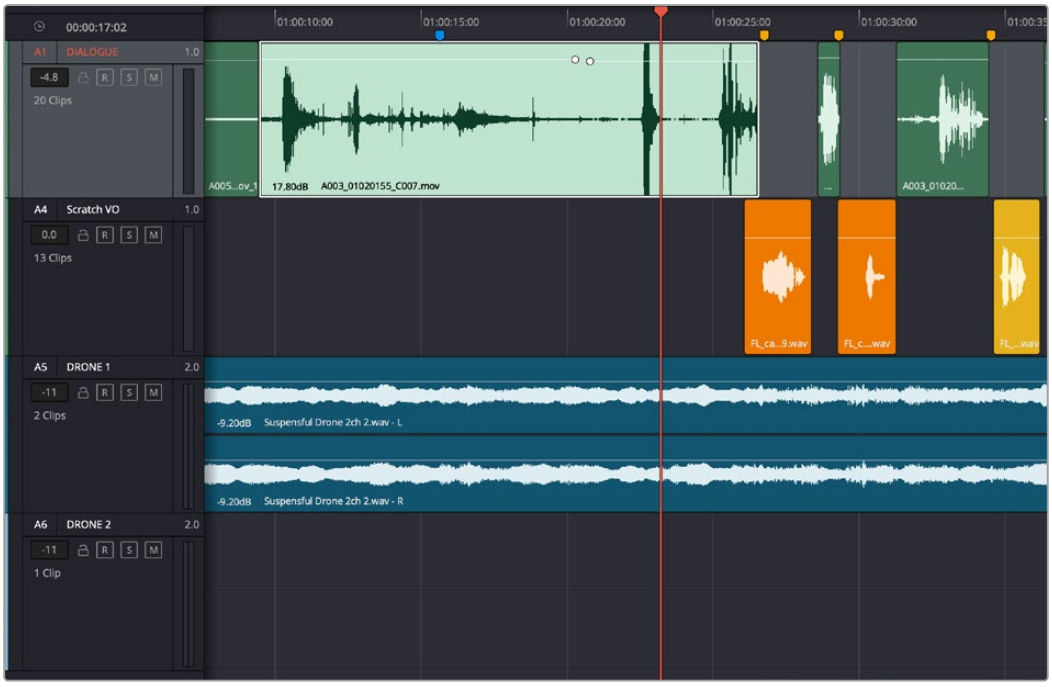
To choose Pointer mode:

- Click the Selection tool (the arrow) in the toolbar.
- Choose Trim > Pointer mode.
- Press A.

To automatically select clips using the playhead position in Pointer mode:

1. Press A to enter Pointer mode.
2. Select one or more tracks with clips you want to select.
3. Move the playhead to intersect those clips.

   All clips that intersect the playhead on selected tracks of the Timeline are automatically selected in their entirety. Automatic selections are illuminated brighter to indicate their selection. Intersecting clips on unselected tracks are not selected.



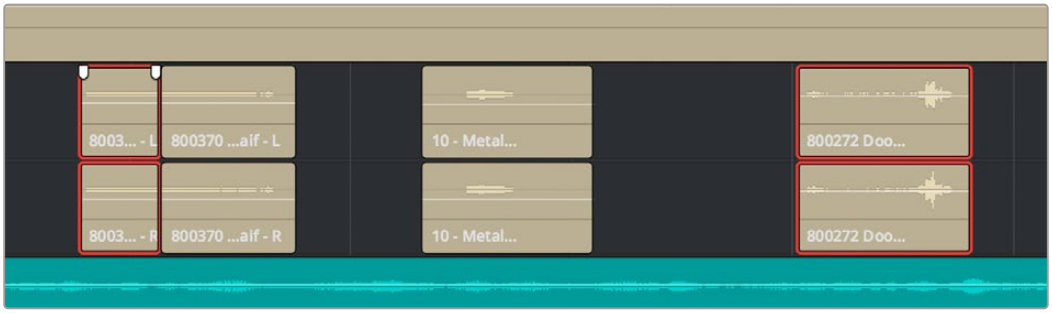
Clips intersecting the playhead in Pointer mode are automatically selected with orange highlights

Methods of selecting clips using the pointer:

- Click any clip to select it.

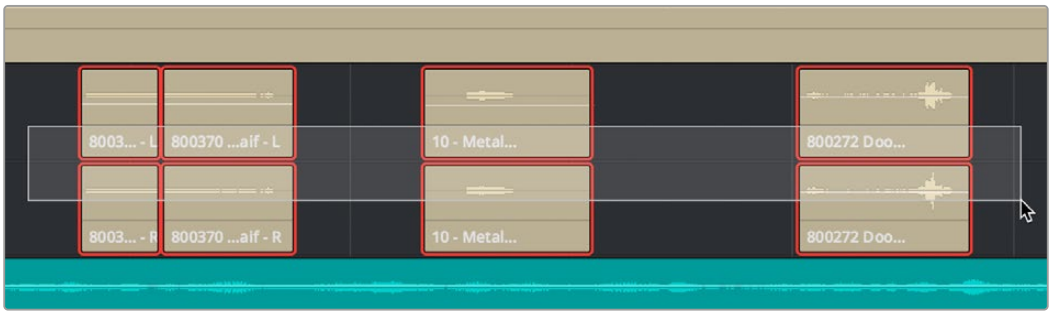
Click a clip to select it

- Command-click multiple clips to select them all at once.



Command-clicking multiple clips selects those clips, even if they're separated by other clips

- Click anywhere in the background of the Timeline and drag a bounding box over multiple clips.



Dragging a bounding box over multiple clips selects all of them

Using Range Mode

Range mode also uses the position of the playhead to make selections of a partial range of clips in the Timeline when using the Fairlight Editing console or keyboard shortcuts. You can also use this mode in conjunction with the pointer and keyboard shortcuts to make partial selections of clips.

- **If no tracks have been selected:** Clips that intersect the playhead are not selected. You can use the pointer to click a clip and select it in its entirety along with the track it's on. You can also use the pointer to drag on one or more clips to select a partial range in preparation for different editing operations. Whenever you make a selection with the pointer, Timeline In and Out points are set to the boundaries of the selection.
- **If tracks have been selected:** Selected tracks are brightened in the Timeline, and any clip on a selected track that intersects the playhead will be automatically highlighted brighter. Clips on de-selected tracks will be ignored. Dragging a crosshairs over one or more clips with the pointer

overrides all automatic selections and selects the regions of the clips you drag over, and the tracks they're on.

- **If you set In and Out points:** Partial regions of all clips on all selected tracks between the In and Out points will be highlighted brighter. Clips on unselected tracks are ignored. While In and Out points are set, the playhead no longer makes automatic selections; you must set new In and Out points to modify the selection in this mode.

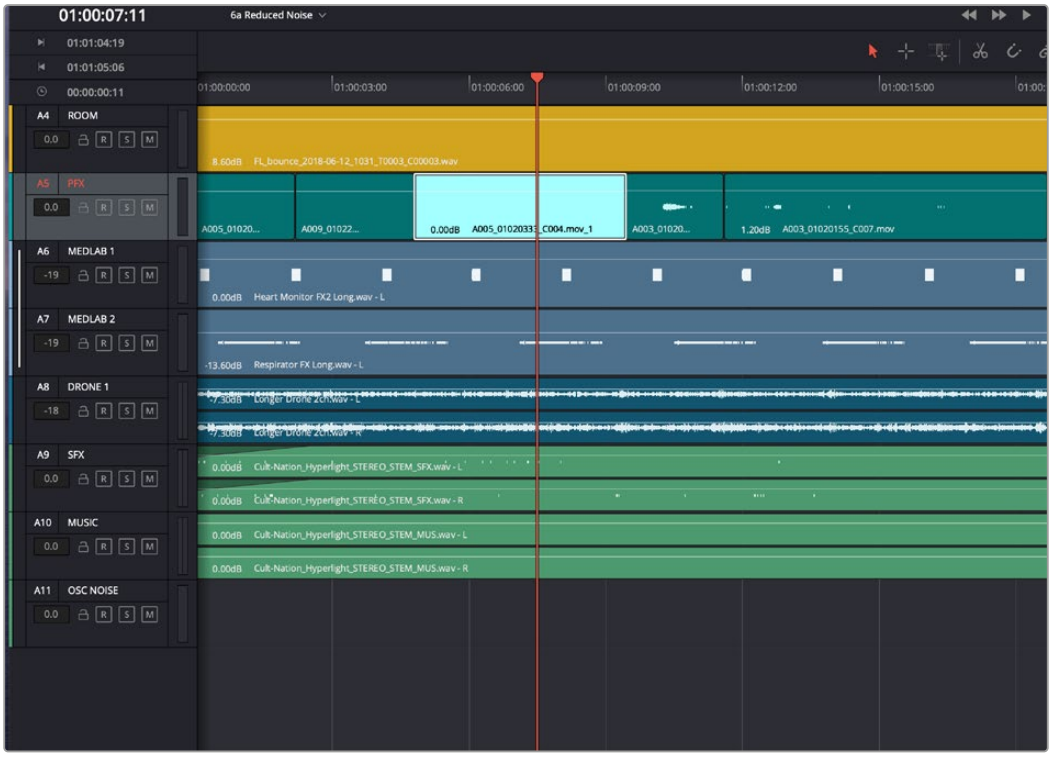
To choose Range mode:

- Click the Range Selection tool (the crosshairs) in the toolbar.
- Choose Trim > Range mode.
- Press R.

To automatically select clips in Range mode using the playhead position:

1. Press R to enter Range mode.
2. Select whichever tracks have clips you want to select.
3. Move the playhead to intersect those clips.

   All clips that intersect the playhead, on the tracks you selected, define a selected range from the beginning of the first selected clip to the end of the last selected clip.

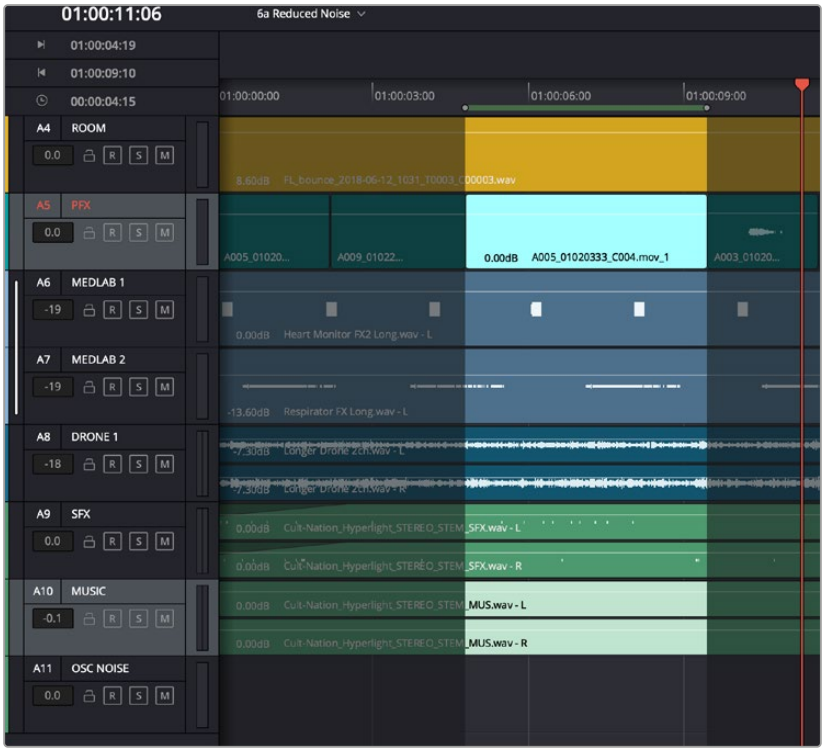


Clips intersecting the playhead on a selected track in Range mode are automatically selected

To create custom clip ranges using In and Out points in the Timeline:

1. Press R to enter Range mode.
2. Select whichever tracks have clips you want to select.
3. Move the playhead and press the I (Mark In) and O (Mark Out) keys to define a range in the Timeline.

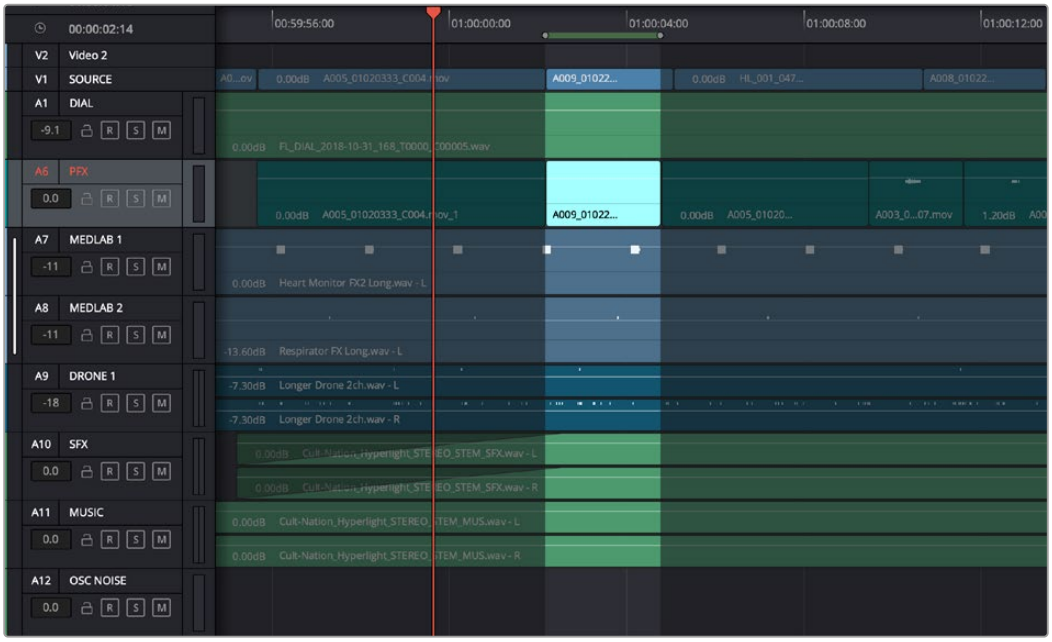
All clip segments that fall within the range of your In and Out points on selected tracks will be selected.



Using the Range mode to select clip segments on selected tracks using In and Out points

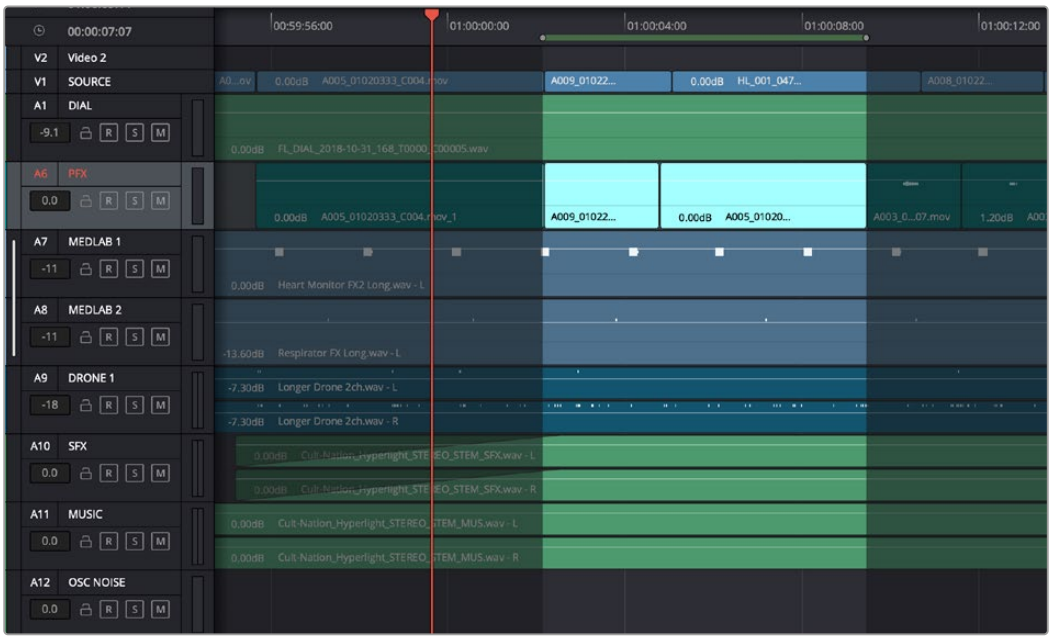
Methods of selecting clips in Range mode via clicking and dragging:

- **To select a single clip:** Click any clip to select both it and the track it's on, and define a range in the Timeline that matches the duration of that clip.



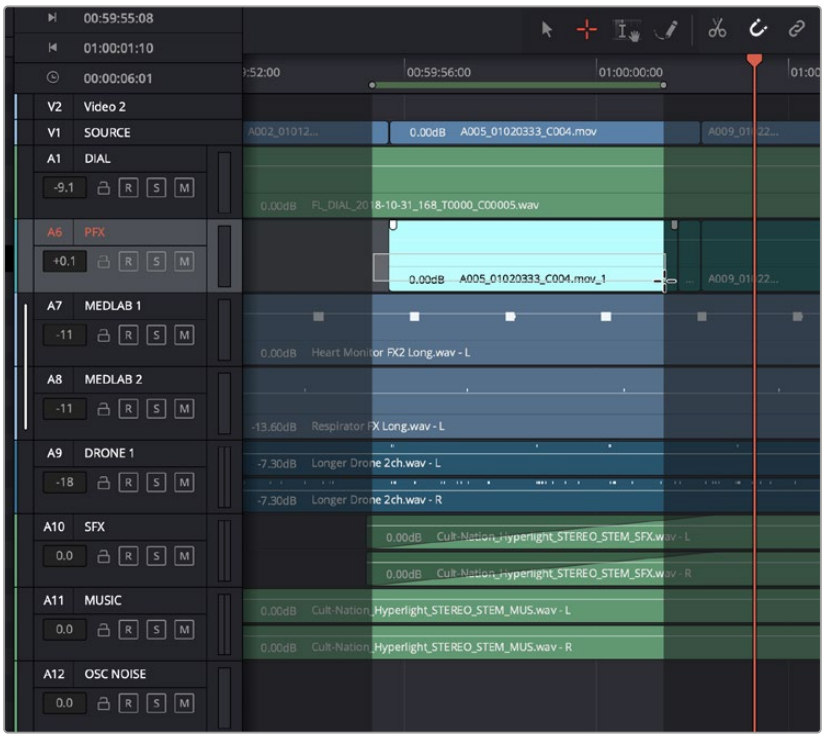
Click to select a single clip as well as the track it's on

- **To select multiple clips:** Command-clicking multiple clips to select them all at once defines a range in the Timeline that matches the total overlapping duration of all clips in the selection, from the beginning of the first selected clip to the end of the last selected clip.



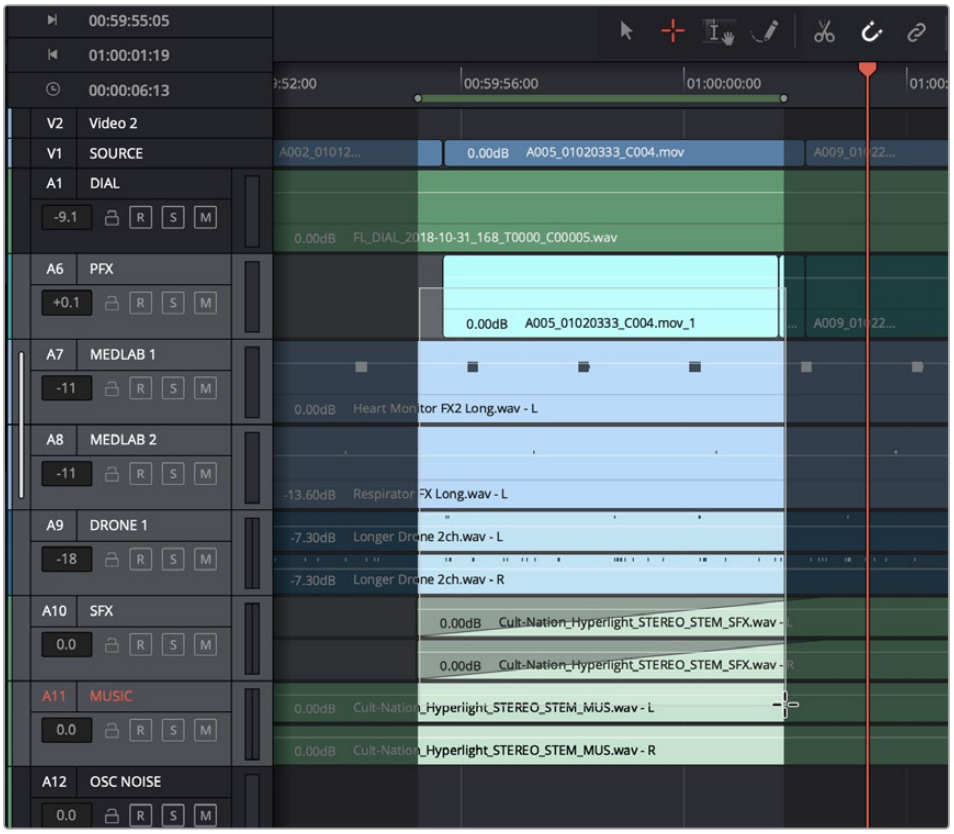
Range selection by Command-clicking multiple clips

- **To drag to select a range within a single clip:** With the Range Selection tool selected, drag anywhere on top of a clip to drag a bounding box over whatever segment of that clip (or of one or more clips) to select both that clip segment and the track it appears on. This is a good way of selecting part of a recording you want to move or delete.



Ranged selection within a clip using a bounding box

- **To drag to select a range within multiple clips:** Click and drag a bounding box over whatever segment of one or more clips you want to select to select both those clip segments and the tracks they appear on. Or, Command-click and drag anywhere on top of any clip to drag a bounding box over whatever region of clips and tracks you like.



Ranged selection across multiple clips using a bounding box

In Range mode, whenever you make a selection, the In and Out point fields update with the range that you've created.

The range fields showing you the In and Out point values that define the current range

These ranges can be cleared if necessary.

Methods of clearing In and Out points to clear the current range:

- Press Option-I to clear the current In point.
- Press Option-O to clear the current Out point.
- Press Option-X to clear both the In and Out points.

Using Focus Mode

Focus mode works as a Multi Tool that is designed for making efficient pointer-based selections and edits, in conjunction with an assortment of commands for extending and editing selections that can be triggered via customizable keyboard shortcuts. If you're editing with a mouse and keyboard, this mode is designed to let you work quickly by enabling a variety of different functions based on clicking different parts of each clip in the Timeline.

Additionally, an important aspect of working in Focus mode is that this is the only mode that lets you edit the Timeline during playback, which you can't do in Pointer and Range modes.

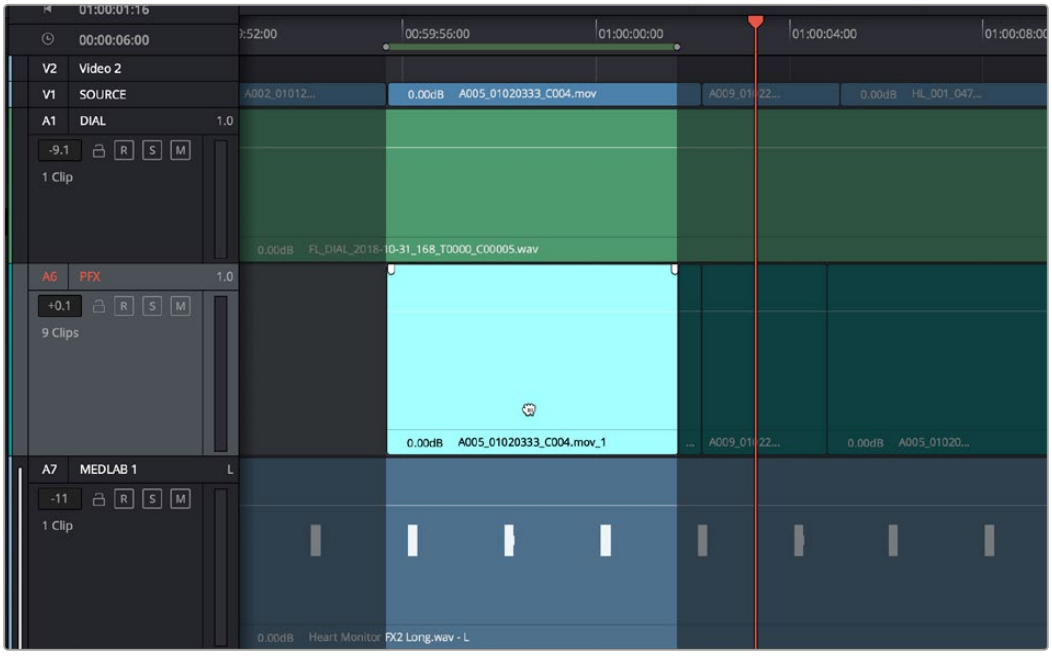
- **If no tracks have been selected:** Whenever you make a selection with the hand, Timeline In and Out points are set to the boundaries of the selection. Whenever you make a selection with the crosshairs, Timeline In and Out points are set to the boundaries of the region you dragged. In all cases, the tracks that contain selected clips and regions of clips are also selected.
- **If tracks have been selected:** Any clip on a selected track that intersects the playhead will be automatically highlighted brightly. Clips on de-selected tracks will be ignored. Dragging a crosshairs over one or more clips with the pointer overrides all automatic selections and selects the regions of the clips you drag over, and the tracks they're on.
- **If In and Out points have been set:** Clicking the bottom half of clips in the Timeline will select that clip and track, and the In and Out points will change to encompass that clip.

To choose Range mode:

- Click the Range Selection tool (the crosshairs at the bottom of a track) in the toolbar.
- Choose Trim > Range mode.
- The keyboard shortcut is pressing - R.

To select an entire clip using the Hand tool of the Focus mode:

- Move the pointer to the bottom half of a clip until a hand cursor appears, and click once to select that clip in its entirety.

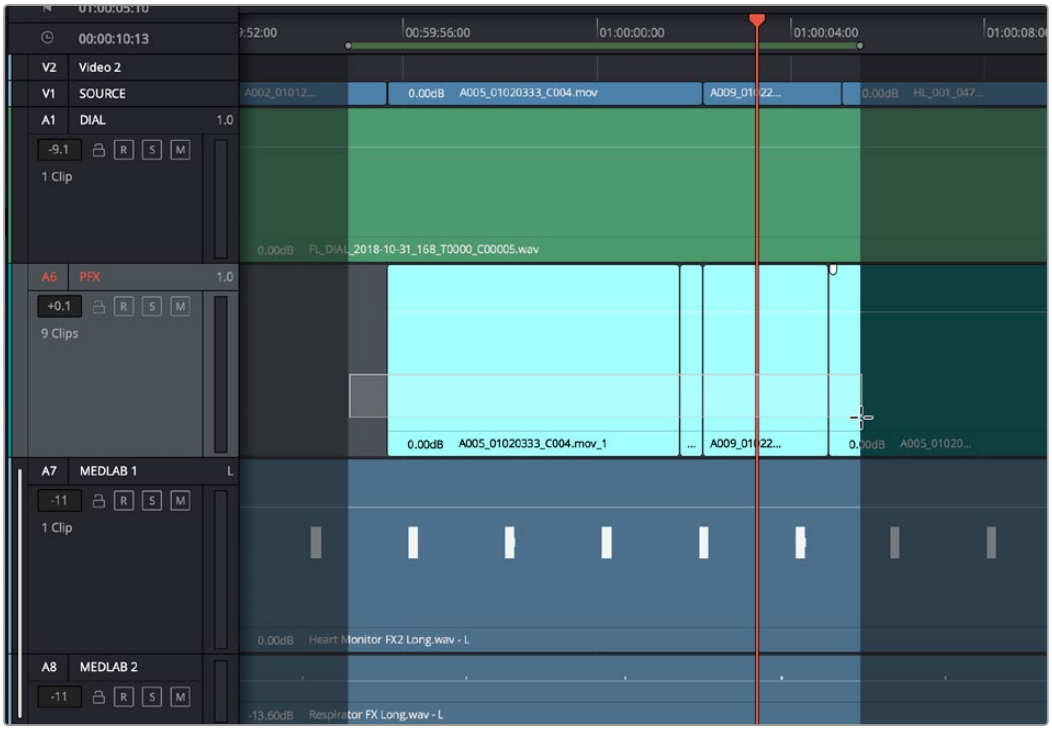


Clicking the bottom half of a clip to select that clip in Focus mode

- Use the Hand to Command-click multiple clips to make either contiguous or noncontiguous selections.
- Use the Hand to Shift-click multiple clips to make contiguous selections.

To select a range using the I-beam cursor of the Focus mode:

- Move the pointer to the top half of a clip until an I-beam cursor appears, and drag to select a region of one or more clips. As you drag, the playhead follows the Out point.



Dragging within the top half of a clip to select a region in Focus mode

- Using the crosshairs, you can also Shift-click to expand or contract the selected region across one or more clips.
- Using the crosshairs, you can also double-click to select an entire clip.
- Partial edit selections that contain a fade will copy with the fade intact.

To select a single frame using the I-beam cursor of the Focus mode:

- Move the pointer to the top half of a clip until the I-beam cursor appears, and click once to place a point selection at the frame you clicked. The playhead also moves to this frame.

Clicking within the top half of a clip to make a single frame selection

- Using the I-beam cursor, you can also Command-click clips on higher and lower tracks to add them to the single frame selection, aligned at the same frame. For example, you could do this to split multiple clips at once. One frame selections can be on discontiguous tracks.

Command-clicking within the top half of multiple clips on multiple tracks to add single frame selections at the same frame

To move a selection using the Hand tool of the Focus mode:

- Once you've made a selection of one or more clips or regions using the Hand or I-beam cursor of the Focus mode, you can move the pointer to the bottom half of any selected clip and drag the selection to another position on the Timeline.

Commands For Editing and Extending the Selection

Once you've made one or more selections in the Timeline, there are a series of commands you can use to modify or expand the selection. These commands were designed to be used alongside the Focus mode, but they can be used in any mode.

Editing the Selection

There are six commands for changing the current selection, moving it from one clip or group of clips in the Timeline to another. These commands only move the range of clips/frames that are selected; they do not move the clips themselves. These commands are found within the Timeline contextual menu when you right-click on a clip.

- **Move To Previous/Next Edit:** Moves the current selection to the next clip/edit point to the left or right in the Timeline.
- **Move To Previous/Next Track:** Moves the current selection to the next track up or down in the Timeline.
- **Move to Previous/Next Frame:** Nudges the current selection to the left or right in the Timeline.

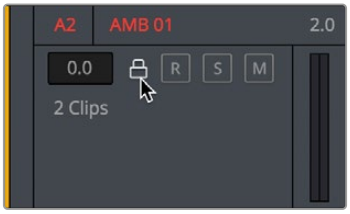
Extend Edit Selection

There are four commands for expanding the range of what's selected in the Timeline, one clip or track at a time. These commands are found within the Timeline contextual menu when you right-click on a clip.

- **To Previous Edit:** Expands the selection to include the previous clip to the left in the Timeline.
- **To Next Edit:** Expands the selection to include the next clip to the right in the Timeline.
- **To Previous Track:** Expands the selection to include the clip in the next track up in the Timeline.
- **To Next Track:** Expands the selection to include the clip in the next track down in the Timeline.

Locking Audio Tracks

Another step you can take to prepare before performing any kind of editorial operation is to lock tracks with media that you don't want to be affected by whatever it is you're about to do. For example, if you have a complex set of music edits on track A3 that you don't want to be affected by operations that will delete media that overlaps it, you can lock track A3 so those clips remain unaffected.



Locking an audio track

Clips on locked tracks cannot be moved, deleted, cut, or otherwise affected by editorial operations. Furthermore, parameters of clips on locked tracks cannot be edited in the Inspector. However, clips on locked tracks can be played back and mixed like any other audio clips.

To toggle the lock or unlock state of audio tracks in the Fairlight page, do one of the following:

- Click any track's lock control to toggle lock on and off.
- Click any track's lock control and drag over the lock controls of other tracks in the Timeline to quickly lock or unlock several adjacent clips.
- Open the Index and click/drag one or more track lock controls to toggle lock on and off.

Splitting Clips

In many situations you may find yourself splitting audio clips in order to separate multiple rolling takes.

To split one or more clips in either Pointer or Range mode:

1. Select each track that has a clip you want to split.
2. Move the playhead to intersect the clips you want to split at the frame where you want the split to happen.
3. Do one of the following:
   a) Choose Timeline > Split Clip or press Command-\ (backslash).
   b) Choose Timeline > Razor or press Command-B.

When you split a clip in the Edit page, a through edit appears to show that you currently have an edit with continuous timecode running from the outgoing to the incoming half. This is called a through edit and is displayed in the Edit page with a dotted line running along its edge so you know that it's special. The Fairlight page doesn't display through edits as of the time of this writing.

Linked Clips in the Fairlight Page

Clips can be linked together in the Fairlight page. When multiple clips are linked, Fairlight editing commands treat all linked clips as if they were a single clip. Anything you would do to a single clip is done to all linked clips at once. Selecting one item of a linked clip selects all items. Editing the In point of one item of a linked clip edits them all.

To link two or more clips together:

1. Select all clips you want to link together.
2. Right-click one of the selected clips, and choose Link Clips from the contextual menu.

   A link indicator at the bottom left of every clip you've just linked shows their new linked status.

Trimming Clips Without Rippling the Timeline

Most basic adjustments in the Fairlight page only affect the selected clip or region of the Timeline. Clips to the right of the adjusted area of the Timeline are generally left alone so as not to inadvertently change sync when you don't expect it. This section covers the most basic parts of the Fairlight page's "seven-point editing" paradigm.

Multi-Point Editing Overview

Each clip in the Timeline has several draggable handles and click targets that let you perform different editing tasks using the pointer.

- **In point:** The left edge of the clip can be dragged to resize the beginning of the clip.
- **Out point:** The right edge of the clip can be dragged to resize the end of the clip.
- **Fade In handle:** A handle at the upper left-hand corner of the clip that only appears when the mouse is positioned over that clip, used to fade the audio in by dragging it to the right, or as part of a crossfade between two audio clips. Fades can be reset (eliminated) by double-clicking the fade handle.
- **Fade In curve:** A handle at the center of the Fade In curve that only appears when the curve is exposed, used to adjust the power of the fade in. This handle can be dragged vertically to change the X-Level of the fade, and horizontally to change the X-Point of the fade. Fade curves can be reset by double-clicking the curve handle.
- **Fade Out handle:** A handle at the upper right-hand corner of the clip that only appears when the mouse is positioned over that clip, used to fade the audio out by dragging it to the left, or as part of a crossfade between two audio clips. Fades can be reset (eliminated) by double-clicking the fade handle.
- **Fade Out curve:** A handle at the center of the Fade Out curve that only appears when the curve is exposed, used to adjust the power of the fade out. This handle can be dragged vertically to change the X-Level of the fade, and horizontally to change the X-Point of the fade. Fade curves can be reset by double-clicking the curve handle.

- **Level:** Considered an editorial characteristic, the level of any given audio clip can be adjusted via a level overlay running across each clip. The level of any clip can be reset to the default 0.0 dB by double-clicking the level overlay.
- **Position:** Clicking anywhere within the middle of a clip in Pointer or Range mode, or on the bottom of Focus mode, lets you drag that clip either forward or backward in time, or to another track.

Resizing the In and Out Points of a Clip

Trimming the head or tail of a clip in the Fairlight page means to resize the In or Out point of that clip, making it shorter or longer accordingly.

To resize the beginning or end of a clip:

- **To shorten or lengthen clips:** Move the pointer over the beginning or end of a clip, and when it turns into the Resize cursor, drag the In or Out point to the left or right to change the clip's length. As you drag the In or Out point of an audio clip in the Fairlight page, an overlay appears showing the waveform of all available media at the head (if you're dragging the In point) or tail (if you're dragging the Out point) of the clip you are resizing.

The overlay seen when resizing the In point of an audio clip in the Fairlight page

To quickly resize the beginning or end of a clip to the very beginning or end of available media:

- Double-click the In point of the clip to move the In point to the very beginning of that clip's media.
- Double-click the Out point of the clip to move the Out point to the very end of that clip's media.

If you resize a clip's In or Out point to overlap one or more neighboring clips in the Timeline, the overlapping parts of the neighboring clips will be overwritten by the clip you've resized.

Trim Start and Trim End

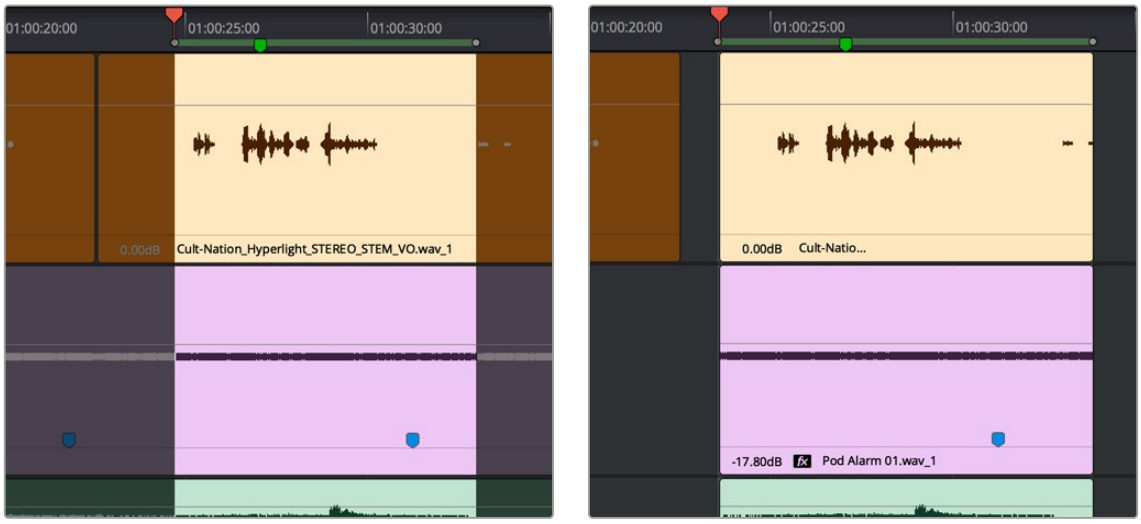
The Trim > Trim Start (Shift-[) and Trim End (Shift-]) commands let you move the In or Out point of all clips that intersect the playhead as either a ripple operation (in Trim mode) or a resize operation (in Selection mode). You do not need to make a selection to use Trim Start and Trim End, making these commands fast to use in the right situation. A classic use of Trim End is when you have several superimposed clips of different lengths that you want to either start or end at the same time.

- Trim Start resizes or ripples (depending on what mode you're in) all clips that intersect the playhead, so that each clip's In point is moved to the current playhead position.
- Trim End resizes or ripples intersecting clips so that each intersecting clip's Out point is moved to the current playhead position.

Clips that don't intersect the playhead are not affected. Furthermore, you can exclude clips on specific tracks from this operation by locking those tracks.

Trim to Selection

The Trim > Trim to Selection (Shift-Command-T) command simultaneously trims the heads and tails outside of a selection of one or more clips so that the selection is all that remains. This command is found within the Timeline contextual menu when you right-click on a clip.



(Left) A selection that includes parts of two clips, (Right) The result of using Trim to Selection to eliminate the heads and tails outside of this selection.

Moving and Overwriting Clips

There are a number of ways to move clips in the Timeline. Clips can be nudged and moved within a track, changing the timing of that clip's position in the edit or they can be moved up or down to other tracks.

To move clips in the Timeline, do one of the following:

- **To move one or more selected clips in the Timeline:** Drag any clip in the Timeline to any other position. If you're in Focus mode, you must drag using the bottom half of the selection. If you drag a clip to overlap another clip, the clip you're dragging overwrites the clip you're moving it over.
- **To nudge one or more selected clips in the Timeline by frame using the keyboard:** Make a selection, then press the Comma key (nudge 1 frame left) or Period key (nudge 1 frame right) to roll the selected edit to the left or right. Shift-Comma and Shift-Period nudges by 5 frames.
- **To move one or more selected clips up or down to other tracks at the same time:** Make a selection, then hold the Shift key down while dragging one of the selected clips up or down in the Timeline to lock their position in time while moving them to other tracks. Or, you can hold the Option key down and press Up or Down Arrow.

Sync Offset Indicator

Audio clips in the Fairlight page display an "out-of-sync" or sync offset indicators when they're moved out of sync with the video items they're linked to.

Snap to Playhead

While in Focus Mode, you can snap the head (beginning) or tail (end) of an audio clip to the playhead location (destination). This is useful when you want to line up audio with an onscreen event, such as a ball smashing a window.

Although “Automation follows edit” works with this function, there are some things to consider:

- This function works even if the playhead is offscreen.
- Clips can only be snapped individually and to a location on the same track.
- A “snapped” clip overwrites existing audio at the destination, even if the affected audio is on the top layer of a layered clip.
- A group of clips on a single track selected in Range mode using the playhead position can also be a destination. However, you would need to snap the clip to the side of the playhead that doesn’t have pre-existing audio you want to keep. For more information Range Mode, see “Using Range Mode.”

To Snap to the clip head to the playhead:

1. Activate Focus Mode and move the playhead to the intended destination.
2. Hold down Command-Option and click the clip you want to move.

   The Audio is now in the new location with the head of the clip snapped to the playhead.

To Snap to the clip tail to the playhead:

1. With Focus Mode active, move the playhead to the intended destination.
2. Hold down Command-Option-Control and click the clip you want to move.

   The Audio is in the new location with the tail of the clip snapped to the playhead.

Subframe Nudging

In the Preferences/User/Editing panel under General Settings you can change the nudge amount by either subframes or by milliseconds for the Fairlight page. These are completely user definable so that you can type your desired nudge amount into the corresponding box.

Be sure to fully investigate this settings panel, which includes pre-roll and post-roll settings and other useful Fairlight adjustments.

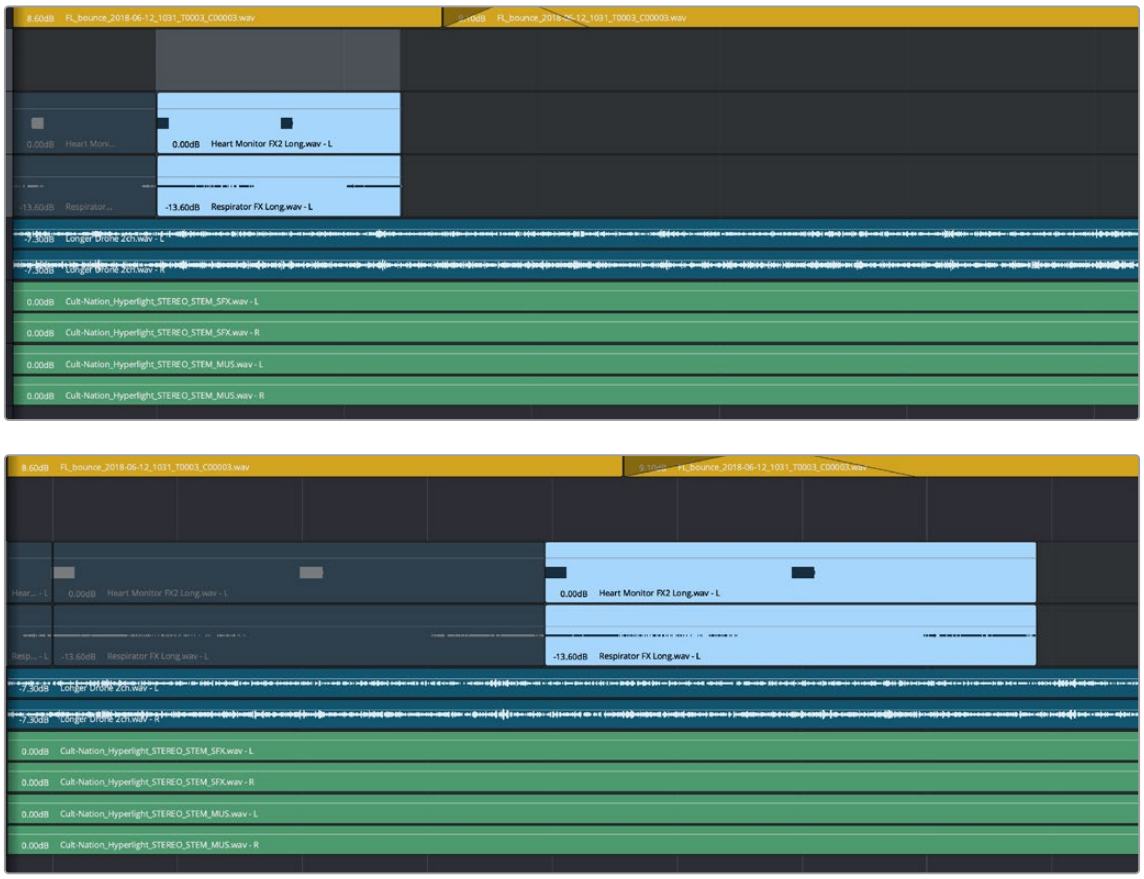
Slipping

Formerly called re-syncing, slipping an audio clip keeps that clip in the same place in the Timeline while changing the range of media that appears in that spot. Slip edits do not change the duration of the overall Timeline, and they don’t move the clip’s position relative to the other clips in the Timeline. Slipping simply changes the range of media that clip represents.

NOTE: While available in previous versions of Fairlight, slipping is not available at the time of this writing.

Duplicating Clips

The Duplicate Selection command duplicates one or more selected clips, placing the duplicates immediately after the Out point of the selection. If you're duplicating a region of a clip with tails, or a clip that's in between other clips, the duplicated selection will overwrite whatever is to the right of the current selection, for the duration of the duplicate.



Using the Duplicate Selection command to duplicate a selected region

If you hold the Option key down while dragging a clip in the Timeline, you'll place a duplicate clip wherever you drop it.

Option-dragging to duplicate a clip in the Timeline

Disabling and Re-Enabling Clips in the Timeline

Sometimes there's one or more audio clips in the Timeline that you don't want to play along with the rest of the edited sequence, but you don't want to remove from the Timeline either, in case you change your mind later. For this reason, it's possible to disable clips, effectively turning them off without removing them. Previous versions of Fairlight referred to this operation as Mute clip.

Disabled clips appear dimmed in the Timeline. They don't play back, they're not rendered, and they're not output to video. However, their position is preserved in the Timeline, so you can always re-enable them at a later time if you change your mind and decide you want to use them.

Disabled clips appear in the Timeline in gray.

To disable or re-enable one or more selected clips:

- Right-click part of the selection and choose Enable Clip from the contextual menu.
- Choose Clip > Enable Clip.
- Press D.

Deleting Audio Clips and Regions

You can delete any clips or clip regions that are selected, in either Pointer or Range modes, by pressing the Delete key, or by right-clicking a clip and choosing Delete Selected from the contextual menu. By default in the Fairlight page, deleting anything leaves a gap. Under the Edit Menu > Ripple Delete you can ripple delete selected clips changing the placement of all of the clips that follow.

Cut, Copy, and Paste

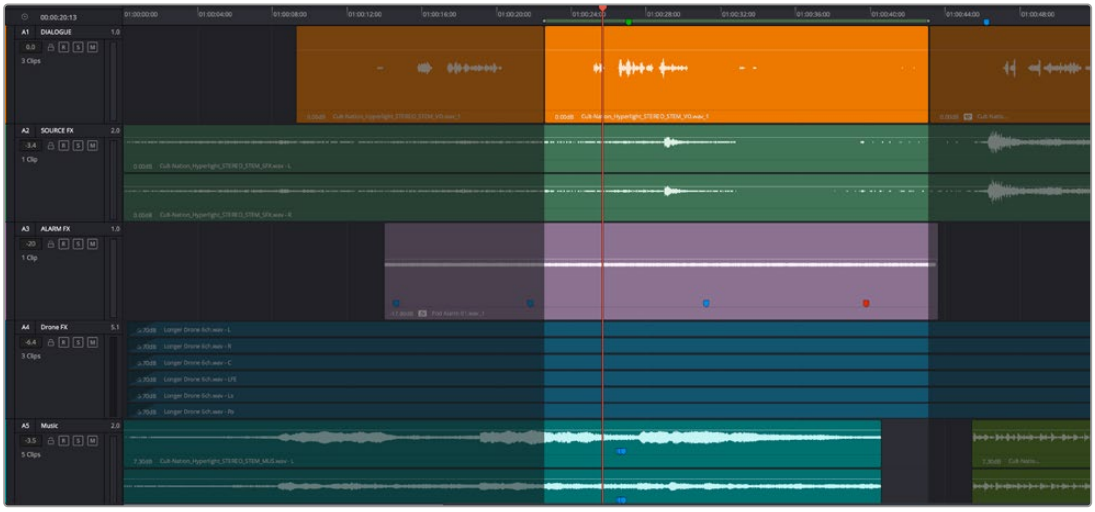
The Fairlight page has a unique copy and paste methodology that takes advantage of the "ghost" overlays that are used for the waveforms of selected audio clips. This method makes it easy to copy and paste clips using keyboard shortcuts and the JKL keys.

Conventional Cut, Copy, and Paste

The typical cut, copy, and paste commands expected of every software application are available in the Fairlight page, but with a unique twist that's particularly advantageous for users of the Fairlight control surface, or for anyone who uses the JKL transport key shortcuts to move around the Timeline for keyboard-driven editing.

To cut or copy and paste either all or part of a clip:

1. If you're cutting or copying a whole clip, then choose either the Selection (press A) or Range Selection (press R) mode. If you're cutting or copying part of a clip, then make sure you're in Range mode (press R).
2. To use the playhead to make a clip selection, select the track that contains the clip you want to copy or cut. If one or more tracks are already selected, you can use the Control-Option-Up or Down Arrow key shortcuts to move the track selection state up or down to the tracks with the clip you want to cut or copy.

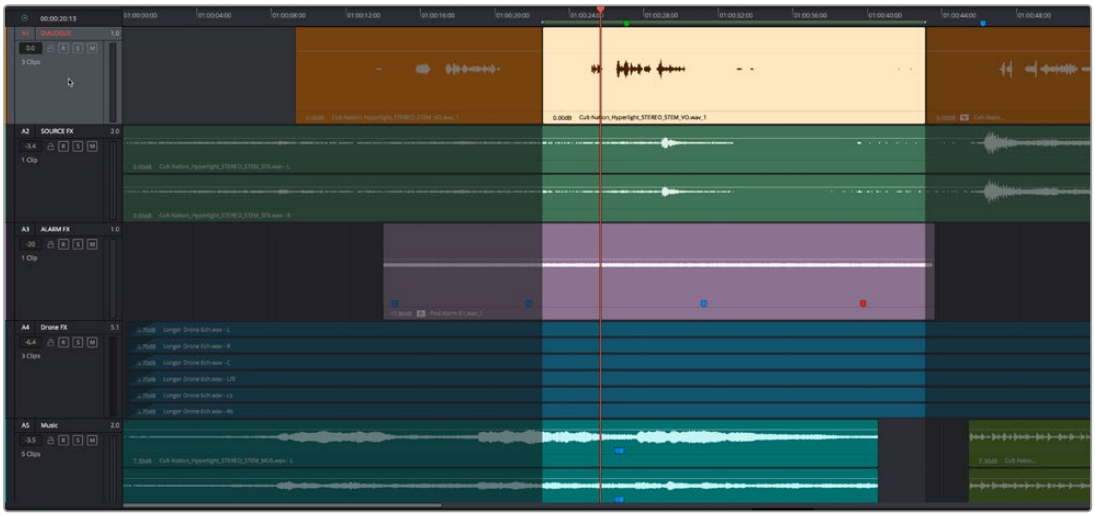


Selecting the track with a clip you need to cut

3 Do one of the following:

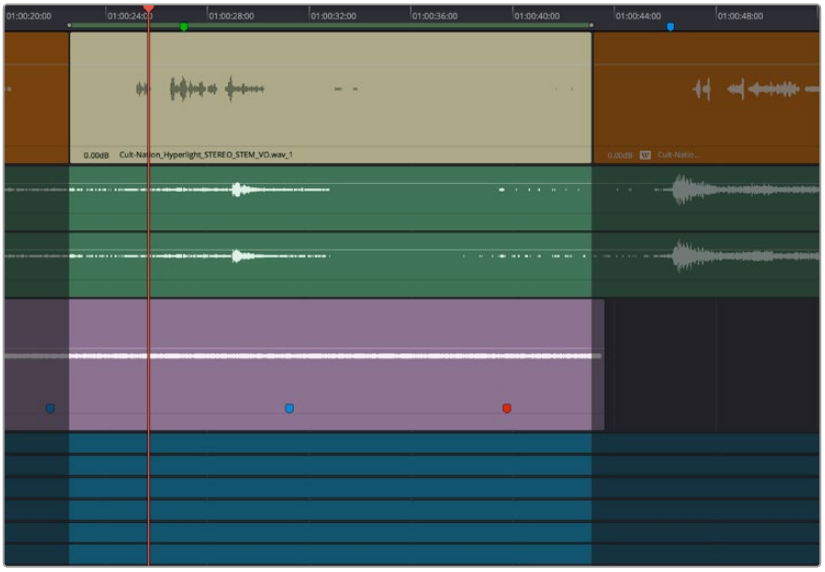
a) To cut or copy a whole clip, move the playhead so that it intersects the clip you want to cut or copy. If the playhead intersects a clip on a selected track, that clip should become selected. You should note that even if you use the mouse to select a clip without selecting a track first, you should still move the playhead to intersect the clip you're copying or pasting, as this sets up an important reference point for the operation.

b) To cut or copy a segment of a clip, move the playhead so that it intersects the clip you want to cut or copy. If the playhead intersects a clip on a selected track, that clip should become selected. Then, using JKL and the I (In) and O (Out) keys, mark a range in the Timeline that includes the segment of the clip you want. That segment should appear highlighted as a result.



Cutting or copying a segment of a clip using In and Out points

4 Making sure the playhead is over the section of the waveform that you want to use as the frame to move the clip by, press Command-X to cut or Command-C to copy that clip (you can also right-click a clip and choose Copy or Cut). That clip will immediately become highlighted.

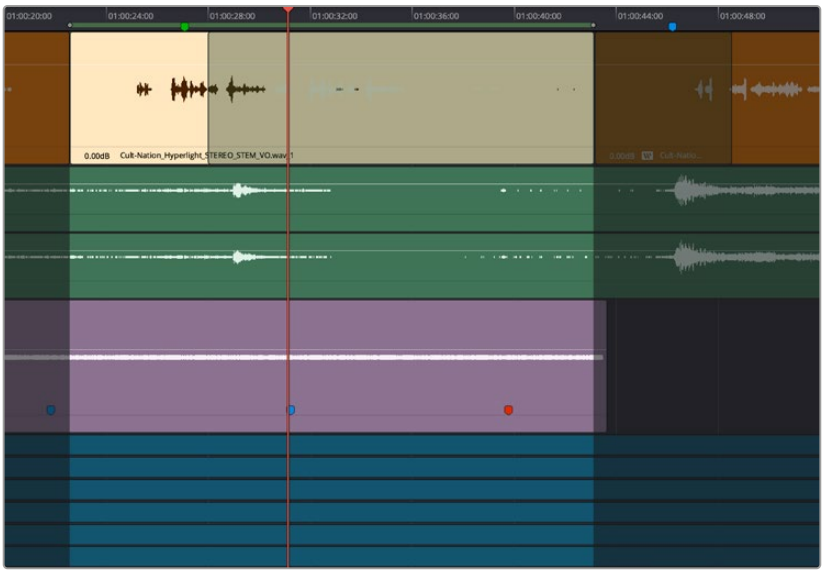


Cutting or copying a clip at the position of the playhead

5 At this point, there are two things you can do to position the cut or copied clip to the position in the Timeline at which you want to paste it:

a) Moving the playhead will now also move the clip you cut or copied, shown as a ghost clip with waveform that's "attached" to the playhead at the frame you chose. Whether you drag the playhead with your mouse or use JKL to move the playhead through the Timeline, the cut or copied clip will move along with it, so that moving the playhead repositions the cut or copied clip on that track.

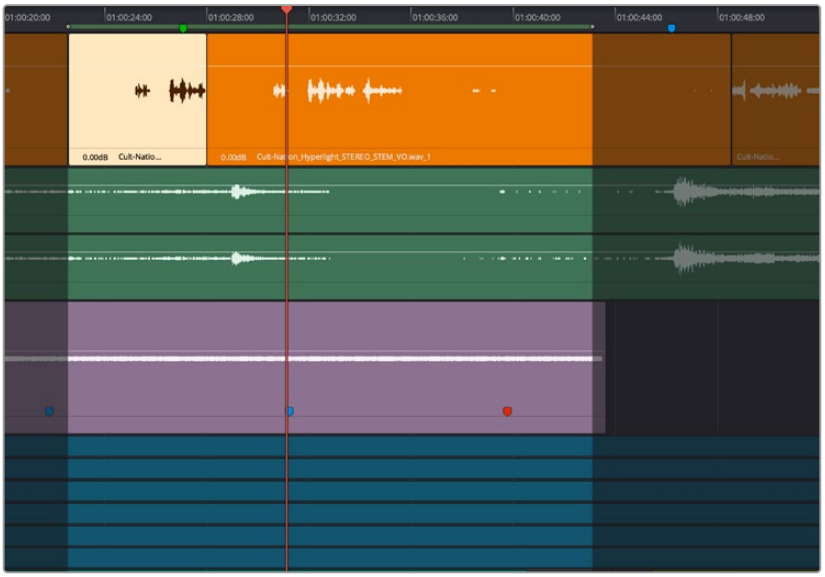
b) If you want to move the cut or copied clip to another track, use the Control-Option-Up or Down Arrow key shortcuts to change the selected track; the ghost clip will move along with change in track selection.



Positioning the cut or copied clip before you paste it

This way, you can use the playhead to align the ghost waveform with other audio clips surrounding it in preparation for pasting it.

6 When the clip is positioned where you want it, press Command-V to paste the clip at the position you've chosen (you can also right-click a track and choose Paste from the contextual menu). The clip becomes solid, and you're finished.



The pasted clip

Using this method of cutting and pasting makes it quick to cut or copy clips using only keyboard commands, with the clip's ghost overlay making it easy to precisely align the clip you're pasting to fit exactly where you need it to, perfectly in sync.

Using the Cut/Copy Head and Tail Commands

Four additional commands make it easy to cut or copy portions of one or more clips that intersect the playhead, either from the In point to the current position of the playhead (the Head), or from the current position of the playhead to the Out point (the Tail).

To cut or copy the head or tail of a clip, and paste the result:

1 Using these commands, there's no need to make a partial selection, so you can use either the Selection (press A) or Range Selection (press T) modes.

2 Select the track that contains the clip you want to copy or cut. If one or more tracks are already selected, you can use the Control-Option-Up or Down Arrow key shortcuts to move the track selection state up or down to the tracks with the clip you want to cut or copy.

3 Move the playhead so that it intersects the clip you want to cut or copy at the frame you want to define, either the end of the head or the beginning of the tail. If the playhead intersects a clip on a selected track, that clip should automatically become selected. You should note that even if you use the mouse to select a clip without selecting a track first, you should still move the playhead to intersect the clip you're copying or pasting, as this sets up an important reference point for the operation.

4 Choose Edit > Cut/Copy Head/Tail to cut or copy the portion of the selected clip you want to paste. That portion of the clip will immediately become highlighted.

5 At this point, there are two things you can do to position the cut or copied head or tail of the clip to the position in the Timeline at which you want to paste it:

a) Moving the playhead will now also move the clip you cut or copied, shown as a ghost clip with waveform that's "attached" to the playhead at the frame you chose. Whether you drag the playhead with your mouse or use JKL to move the playhead through the Timeline, the cut or copied clip will move along with it so that moving the playhead repositions the cut or copied clip on that track.

b) If you want to move the cut or copied clip to another track, use the Control-Option-Up or Down Arrow key shortcuts to change the selected track; the ghost clip will move along with change in track selection.

This way, you can use the playhead to align the ghost waveform with other audio clips surrounding it in preparation for pasting it.

6 When the clip is positioned where you want it, press Command-V to paste the clip at the position you've chosen (you can also right-click a track and choose Paste from the contextual menu). The clip becomes solid, and you're finished.

Paste and Remove Attributes

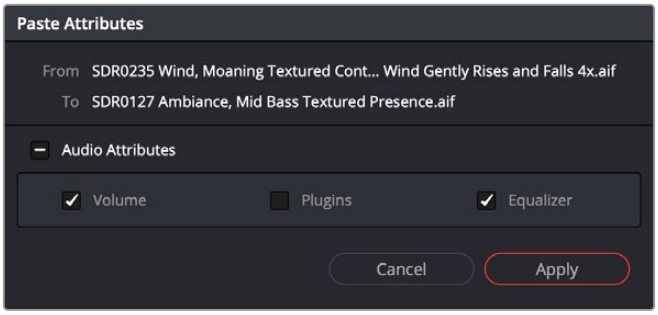
The Fairlight page has Paste Attributes and Remove Attributes commands that allow for the copying and resetting of audio parameters and effects, similar to the same commands on the Edit page.

Clip Attributes Naming

By double-clicking any clip in the Timeline, you can access the Clip Attributes window to rename the clip. You can still access this window with a right-click, revealing the dropdown menu of options.

Copying and Pasting Clip Attributes

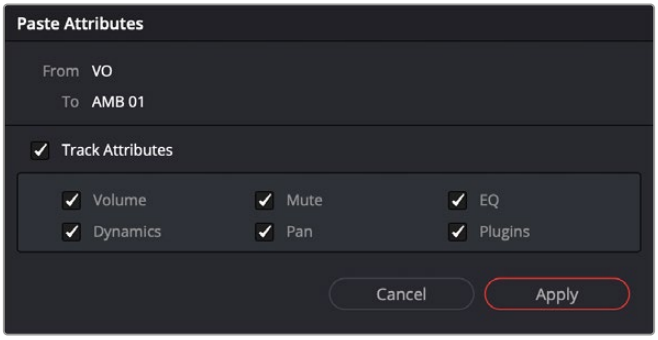
For clips, this works as simply as copying a clip, then selecting one or more audio clips and right-clicking another clip and choosing Paste Attributes from the contextual menu. A dialog appears letting you choose which audio attributes you want to paste before clicking Apply.



The Paste Attributes dialog in the Fairlight page

Copying and Pasting Track Attributes

For tracks, it works a little differently. Right-click on a track header and choose Copy Attributes to copy all track settings and effects. Then, select one or more other track headers, right-click the selection, and choose Paste Attributes. A dialog appears letting you choose which track attributes you want to paste before clicking Apply.



The Paste Attributes dialog in the Fairlight page, used to copy attributes from one track to another

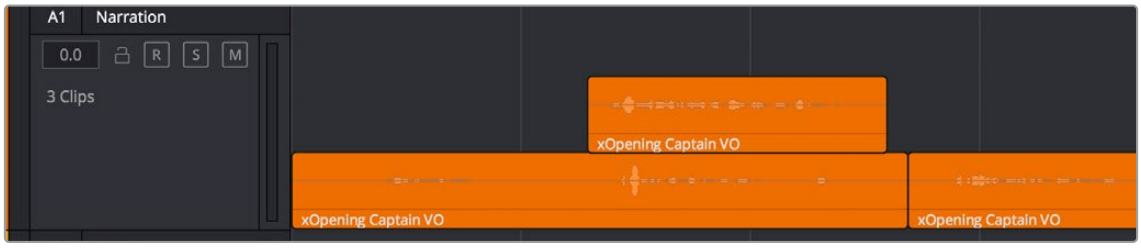
Removing Attributes

For either clips or tracks, you can right-click and choose Remove Attributes to open a dialog with which to choose which attributes you want to reset to their default settings.

NOTE: By choosing the Volume check box in Remove Attributes you will delete all of the Clip Gain keyframes that have been added to a clip.

Audio Clip Layering

Audio layering is a special audio editing mode that lets you superimpose multiple audio clips in the same track, with audio clips edited into the top layers muting overlapping sections of audio clips appearing on lower layers. With audio layering enabled, superimposed audio clips are treated similarly to superimposed video clips that have opacity set to 100%, with clips on top obscuring (or muting) clips underneath.



An example of multiple audio performance editing using layers, where the top layer mutes overlapping sections of audio clips in lower layers

Audio layering is incredibly useful for any situation where you're combining segments of multiple takes together to create a single voiceover, audio vocal track, or dramatic performance, as you can choose which segments to use via their superimposed position in the stack of clips appearing in that track, while at the same time you're preserving the other takes underneath in case you might want them later.

TIP: Track layering can be used on the Edit page as well.

To enable audio layering:

- Choose Timeline > Layered Audio Editing so that a check mark appears by the command. All overlapping audio will be layered instead of overwritten from that point forward.

To view audio layering:

1. Choose View > Show Audio Track Layers to reveal track layers for each audio track (and each lane within a given audio track) in the Timeline. When layering is on, space appears at the top of each track in the Timeline which provides a region into which you can edit layered audio clips.
2. To edit an audio clip or segment as a layer within a particular audio track, drag it from elsewhere in the Timeline or from the Media Pool, and drop it into the empty area above whatever audio is already in that track.

Dragging an audio clip to become layered above another clip

3. Edit the different superimposed layers of audio such that the segments of each take that you like are on top. Only the topmost clip segments will be audible. Audio segments that overlap underneath are silent. To put another layer on top, drag it from its current position to the empty area at the top of the track.

Dragging a bottom audio layer to appear on top

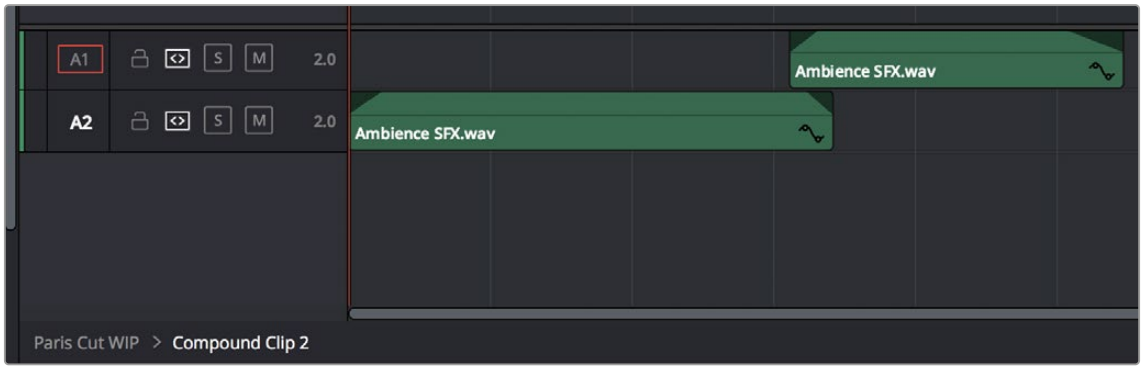
4. When you're finished editing clips in track layers, choose View > Show Audio Track Layers again to hide the individual layers, so that only the topmost clips appear as a flat sequence in each track and lane.

Hiding layers makes all audio layers appear on a single track, as if the top clips are overwriting what's underneath, except the muted material underneath is preserved

Audio Compound Clips

DaVinci Resolve supports audio compound clips, which are created just like any other compound clip, by selecting multiple audio clips, right-clicking one of them, and choosing New Compound Clip. Alternately, compound clips with video clips may now contain multiple audio items as well.

When compound clips containing audio are opened in the Edit or Fairlight pages by right-clicking an audio compound clip and choosing Open in Timeline, breadcrumb controls appear beneath the Timeline that let you exit the compound clip and get back to the master Timeline.

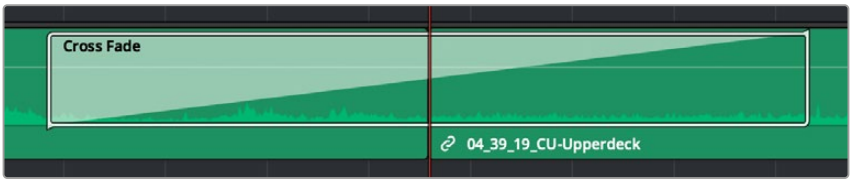


Opening an audio compound clip; note the path control at the bottom left of the Timeline

Audio Crossfades

You can add Cross Fade transitions to any edit point between two audio clips that have enough handles similarly to how you add video transitions, by dragging and dropping from the Effects Library, by right-clicking an edit and choosing an option from the contextual menu, or by selecting an audio edit point and choosing Timeline > Add Audio Only Transition (Shift-T).

Cross Fade transitions are a quick and easy way to fade the volume of the outgoing clip down while simultaneously fading the volume of the incoming clip up, letting you create a smooth aural transition between two audio clips.



An audio Cross Fade transition applied between two clips

You can double-click a Cross Fade transition to open it into the Inspector, revealing the following parameters:

- **Duration:** The duration of the transition, shown in both seconds and frames.
- **Alignment:** A dropdown that lets you choose the transition's position relative to the edit point it's applied to. Your choices are "End on Edit," "Center on Edit," and "Begin on Edit."
- **Transition style:** You can choose –3dB, 0dB, or +3dB to set both the Fade In and Fade Out levels to the same value. For more information on what these levels mean, see the following parameter.
- **Fade In/Fade Out levels:** There are three options that affect the incoming and outgoing halves of the Cross Fade effect independently. 0dB applies a linear fade (this is the default). +3dB applies a

boosted curve; when applied to both Fade In and Fade Out, this can compensate for diminished levels in the middle of a Cross Fade. –3dB applies an attenuating curve, which deliberately lowers the level of the Cross Fade.

Crossfades can be created and edited on both the Edit and Fairlight pages.

Fades and Crossfades

Part of audio editing in the Fairlight page is the use of fades and crossfades. This section shows you how to create these effects for smoothly segueing from one audio clip to another.

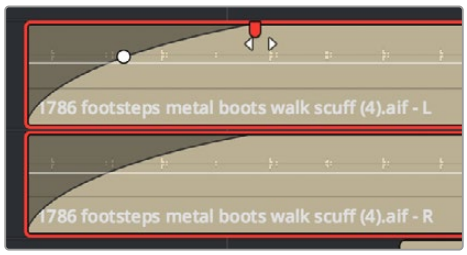
Basic fades can be created on Dolby Atmos master files placed on a timeline as a clip. However, complex fades and batch fades are not supported.

Using Fades

Like the Edit page, each audio clip has fader handles that appear at the upper right and left corners of a clip you're hovering the pointer over.

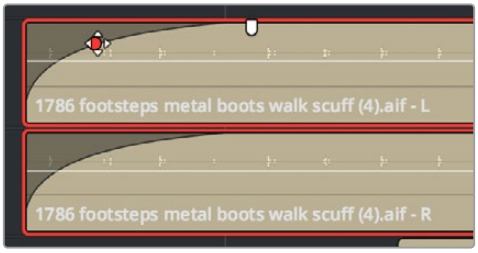
Fader handles appear when you hover the pointer over a clip

Pulling these handles out creates a fade effect with a duration equal to the length you extended the handle.



Creating a fade effect by pulling out one of the fader handles

Once you've created a fade effect, you can adjust the curve of the fade by dragging the handle that appears right on top of the fader curve. Dragging the handle up and down affects the angle of the curve, and dragging the handle left and right affects the shape of the curve. In this way, you can create all manner of fade effects.



Adjusting the curve of the fade

Batch Fade and Crossfade Editor in the Fairlight Page

Multiple fades are available to multiple clips with multiple tracks selected, significantly increasing fade functionality. The Batch Fades window has fade shapes for Fade In, Cross Fade, and Fade Out. The Fade Length is user definable by frame for each of these fade types, and there is an option to overwrite existing fades on the highlighted clips.

All of the settings in the Batch Fades window

There are six options per Fade type for precise usage. When adding Fades between sources, it's important to determine the shape so that only the desired media is included in the fade. The curves indicate the ramping slopes of the fade.

Each box has similar controls for affecting the individual Fade type.

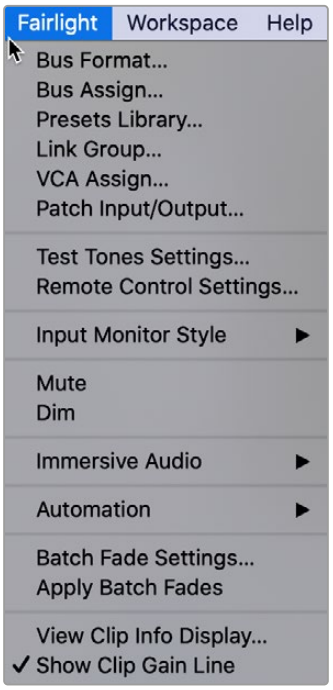
1. Next to the Fade type name is the on/off toggle
2. There are six Fade curves to create the precise fade needed.
3. A Length box determines how many frames the fade will extend,
4. A click box to overwrite any previous fades, if needed.

The Crossfade box has three additional controls.

1. Equal Power maintains the signal level through the fade.
2. Equal Gain is used when crossfading media that could phase when combined. For instance, if a music cue is crossfaded at the mid-point of the fade, there could be a jump in level or added phasing issues. Using this option maintains the gain across the fade for that type of media.

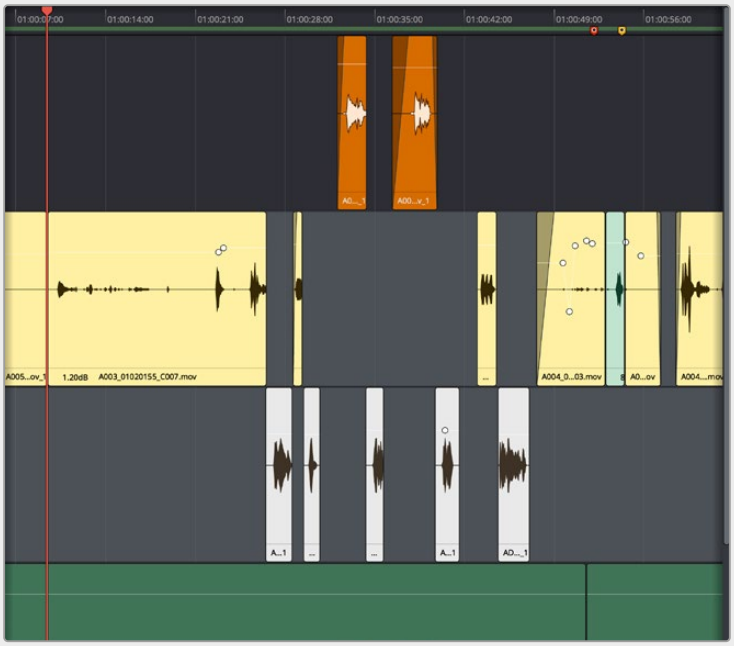
3 Unlinked allows for a different curve type on either side of the crossfade.

This window will retain the settings that were last made so once a series of Fade types have been chosen, then Batch Fades can be made without opening this window and can be accessed via the Fairlight menu with a single click across highlighted regions. The Apply Batch Fades in the Fairlight menu are applied with the settings made in the Batch Fades window.



Batch Fade options in the Fairlight menu

This graphic shows highlighted clips and tracks ready to have Batch Fades applied.



Tracks and clips highlighted for Batch Fades

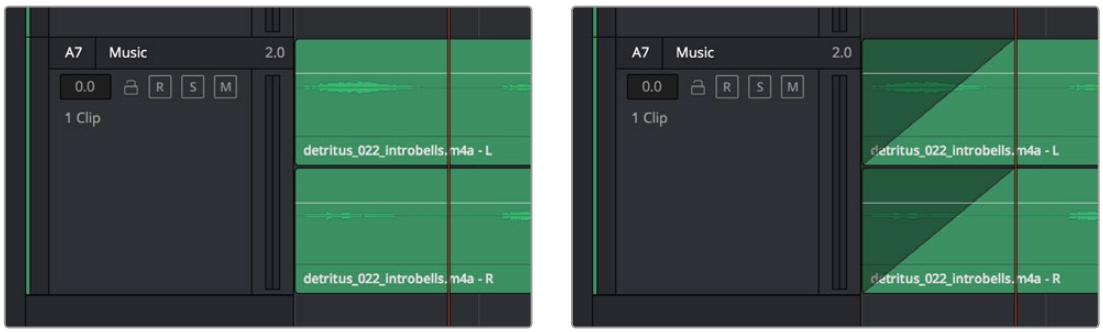
The graphic below shows how the Batch Fades are applied. Clips that are not connected have Fade In and Fade Out applied. Clips that are connected have Crossfades applied. The Batch Fades window determines each of the Fade parameters and then applies them to all of the selected clips. In this example, the Overwrite box was unchecked. Compare the fades that were already there and see that they retain their original Fade length and shape.

All of the highlighted clips have been faded according to the Batch Fades window.

NOTE: If the media is too short, a dialog box will alert you that there are insufficient handles and that the fade could not be created. You can then choose to trim clips, skip clips, or cancel the Batch Fade. If you cancel, you can then alter the settings to better suit the media.

Fade In and Out to Playhead

A pair of commands in the Trim menu let you move the playhead over a clip, and use the playhead position to “Fade In to Playhead” or “Fade Out to Playhead.” These commands work in both the Edit and Fairlight pages.



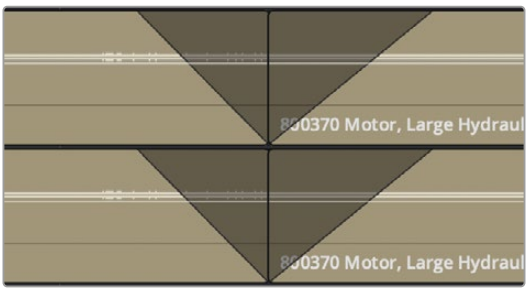
(Left) Placing the playhead where you want a fade in to end, (Right) Using Fade In to Playhead

Creating Crossfades With Overlapping Fades

While a fade gradually fades a single track of audio up or down, a crossfade fades two overlapping clips at the same time, fading one clip up and another clip down, for the aural equivalent of a cross dissolve. There are currently two ways of creating a crossfade in the Fairlight page. Both depend on clip layering to allow you to have overlapping fades over overlapping clips.

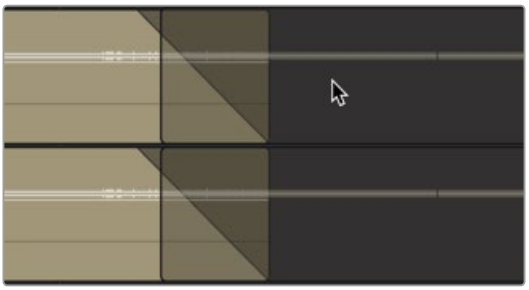
To create a crossfade by overlapping two clips together:

1 Add a fade out to the end of one clip, and a fade in to the beginning of another clip. By default, all fades you add in this way are linear, although you can adjust them to whatever gain you want.



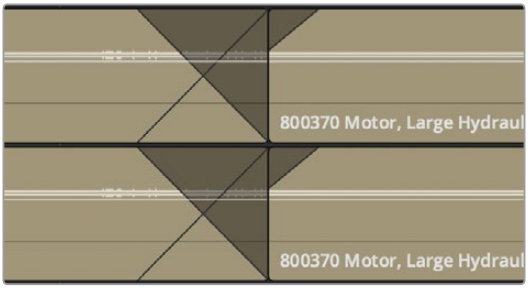
Adding fades to adjacent clips

2 Drag the first clip to overlap the second clip by the length of the fade you've created.



Dragging the clips to overlap, the overlapping parts will be preserved via clip layering

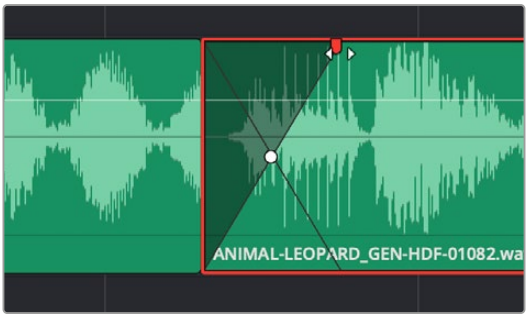
3 Drop the clip. The overlapping fades will both be preserved thanks to clip layering, and a crossfade will appear in the Timeline.



The resulting crossfade

To create a crossfade over two clips that are already layered:

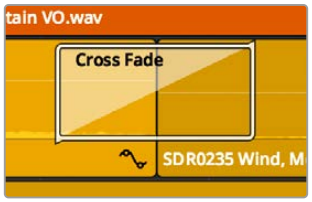
- Drag a fader handle at the beginning or end of a clip that's layered, and a crossfade will automatically appear.



Creating a crossfade by adjusting the fader handle of a layered clip

Using Crossfades From the Edit Page

You can also add crossfades in the Edit page, but they appear in the Fairlight page as transitions in the Edit page style.



The resulting crossfade

Finding Clips in the Media Pool

You can right-click any clip in the Timeline and choose Find in Media Pool to automatically select that clip in the Media Pool, for instances where you might want to edit another copy of that clip somewhere else in the Timeline, or re-edit another segment from that clip into the same area.

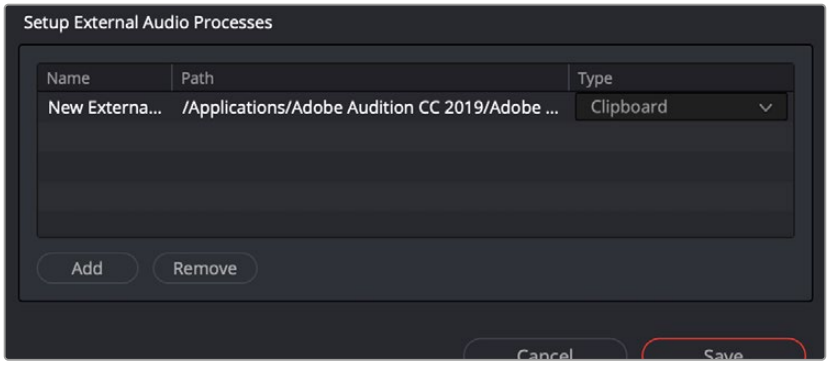
NOTE: Automation Follows Edit when clips with embedded automation are moved or pasted from the Timeline. When clips with automation are instead pulled from the Media Pool, they are in their default state with no automation attached.

Changing Clip Color in the Timeline

You can right-click one or more selected clips in the Timeline to change the clip color, to be more organized. For example, you might set production audio clips containing dialog from different actors to different colors, or you could set clips with dialog, music, and effects to different colors in order to easily differentiate each clip's purpose.

Editing Audio Clips in External Editors

While working in the Fairlight page, you have the ability to process an audio file using a third-party application if necessary, in the event you need to use another application's capabilities to create an effect or solve an issue that can't be accomplished in the Fairlight page itself. To do this, you must first add one or more applications to the External Audio Process list in the Audio Plugins panel of the System Preferences.



The External Audio Process list configured to send audio to Adobe Audition

To add an external audio process:

1. Open the System tab of the DaVinci Preferences, and select the Audio Plugins panel.
2. Click the Add button in the "Setup External Audio Processes" section.
3. To give the audio process a different name, double click in the Name column and type a new name.
4. Double-click in the empty Path column for the new process, and choose an application to assign to that process from the dialog.
5. Choose the type of process you want it to be from the dropdown menu in the Type column.

Once you have one or more external audio applications configured in Preferences, you can use them to process any audio clip in the Fairlight page by right-clicking an audio clip and choosing the application you want to use from the External Audio Process submenu of the contextual menu.

When you do this, a duplicate of the audio clip media is copied (bounced) to the directory location specified by the "Save clips to" field of the Capture and Playback panel of the Project Settings. At that point, the external application is either opened or launched as a command from the command line (depending on how the external application has been configured in Preferences).

Once the bounced audio is opened in the external application, you can process it however you need to and bake in any changes made by saving/rendering/outputting and overwriting the original copied audio media file. DaVinci Resolve detects when changes have been made, and the altered result is automatically reimported as an additional audio layer on top of the original clip in the Timeline.

The way an audio application is configured in the DaVinci System Preferences dictates how the bounced audio file is passed to the external program. There are three choices:

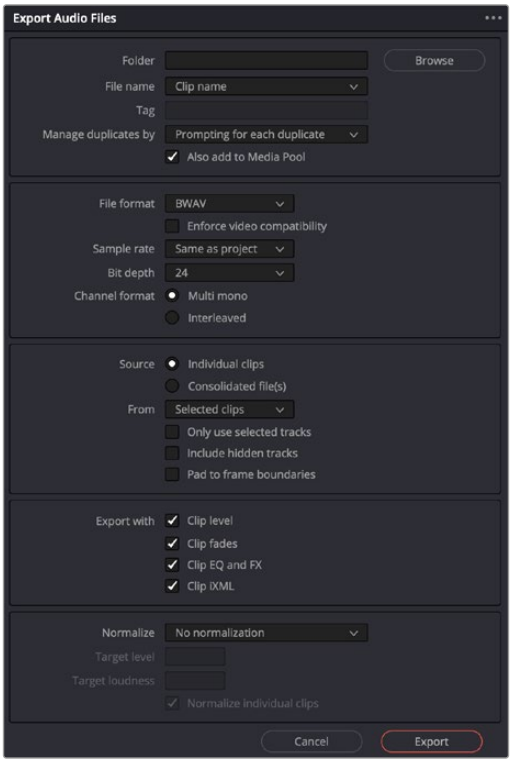
- **Command Line:** As a command line parameter, if your audio application is able to be run from the Terminal.
- **Clipboard:** By placing the path to the bounced file in the clipboard, so you can paste it into the application which has been automatically launched, or import it via a File > Open dialog.
- **Reveal:** By revealing the bounced copy in the file manager of your workstation, so you can drag and drop it onto the application which has been automatically launched.

Exporting Audio Clips to External Files

For any workflow where you need to write clips from the Timeline to external files with extensive file altering capabilities, you can use the Export Audio Files command.

To export clips to external files:

1. Select one or more clips in the Timeline.
2. Right-click the desired selected files and choose Export Audio Files from the contextual menu.
3. When the Export Audio Files dialog appears, choose the following:
   a) Click Browse to choose a location to save the exported audio files.
   b) (Optional) Enter a tag and one of the various Name options.
   c) Choose a File Format, Sample Rate, and Bit Depth for the exported files.
   d) Choose a Channel Format of Multi-Mono or Interleaved for the exported files.
   e) Choose a Source of Individual Clips or Consolidated Clips; a dropdown menu further defines the ranges of the complete timeline, a selected range, or just the selected clips.
   f) Checkboxes can further define using only the selected tracks, including hidden tracks and padding to frame boundaries.
   g) When exporting you can choose to include the Clip Level, the Clip Fades, the Clip EQ and FX, and the Clip iXML.
   h) The exported files can be normalized to predetermined target levels and target loudness values with all of the standards offered throughout the Fairlight page.



The dialog that lets you choose options for exporting clips to files

4. Click Export.

   The selected audio files are written to the location you chose.

Sample Editing

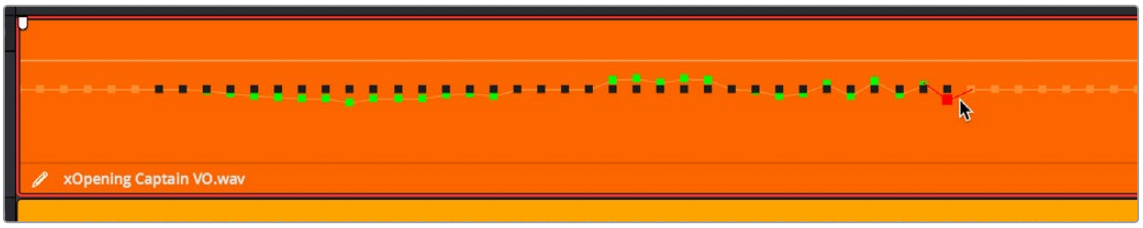
You can zoom quite far into audio clips on the Fairlight page timeline, until you see the individual samples that comprise the audio waveform of each clip. Samples are represented by control points once you've zoomed in far enough.

When you zoom in far enough, you can see the individual samples of an audio clip as control points

You can non-destructively edit these control points to eliminate clicks and pops, and to effect other fixes to problem audio clips.

Methods of editing audio samples:

- **To see the editable audio samples:** Zoom all the way into an audio clip until you see the sample control points, using either Command-Plus or Command-Minus, the scroll wheel of your pointing device, or by holding down the ZOOM button of your Fairlight editing panel and turning the JOG/EDITING wheel.
- **To edit a single audio sample:** Click and drag that audio sample up or down to change its height.
- **To edit a section of samples:** Click and drag horizontally left or right across the samples you want to edit to "redraw" the waveform any way you'd like.
- **To reset all edited samples to their original state:** Right-click an audio clip with edited samples, and choose Reset Edited Samples from the contextual menu.



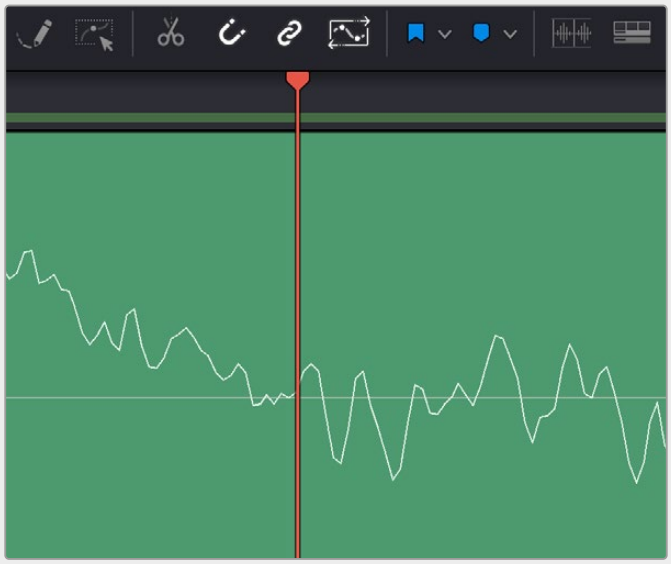
Black points show the previous levels when samples have been edited in a clip

Sample editing can be undone, just like any other editing procedure, as the edited sample points are stored non-destructively within the DaVinci Resolve project.

Waveform Zero Crossing Indicator

Waveforms have a zero crossing indicator line. Since a waveform is an image representation of sound continually moving positive to negative, the zero crossing point is the level at which that fluctuation occurs. When zooming into a waveform at the sample level, the waveform will display the zero crossing line to enable precise editing.

The zero crossing is a useful feature when editing audio, since clean edits are made at the zero crossing to avoid inducing clicks or pops. A crossfade between two audio clips automatically brings both sides of the fade to the zero crossing.



The center line in the waveform indicator is the zero crossing.

Chapter 173

The Fairlight Inspector

Each Timeline and Media Pool clip and every audio track or bus have settings and properties that can be adjusted, animated, and edited in the Fairlight Inspector. This lets you easily perform tasks, such as matching the levels or EQ of several clips while reserving the track level for your overall mix or adjusting levels or audio effect parameters on tracks and busses.

It is important to note that clip-based effects differ from real-time track and bus effects in that they only apply to individual clips on the Timeline or in the Media Pool, rather than all clips on a track.

This chapter describes how to use these controls within the Fairlight Inspector.

Normalizing Audio Levels 3670
Paste and Remove Attributes for Clips and Tracks 3672

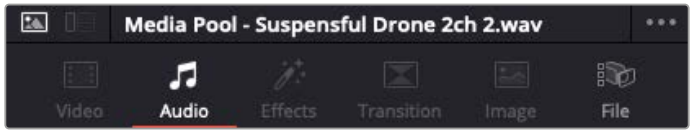
Clip Mode vs. Track Mode

The Inspector includes a Clip Mode and Track Mode button to eliminate confusion about whether your parameter property changes in the Audio tab are applied to an audio clip or a track.

(Left) the Clip mode (circled); (Right) the Track mode (circled)

- Selecting an audio clip in the Media Pool or on the Timeline activates the Clip Mode button, and the clip name appears at the top of the Inspector, to the right of the Track Mode button.

  When you select a Media Pool clip, the term “Media Pool “ appears before the clip name at the top of the Inspector. Only the clip name will be displayed if you select a timeline clip.



The term “Media Pool “ appears before the clip name at the top of the Inspector

- Clicking the Track Mode button while a Timeline clip is selected causes subsequent changes in the Audio tab to apply to the corresponding Mixer channel. The clip name at the top of the Inspector will switch to the track name.
- Clicking a track header also activates track mode.
- In either instance, the clip name at the top of the Inspector will switch to the track name.

Common Controls

Selecting an audio clip, audio track, or bus channel strip in the Mixer exposes some common audio-specific parameters and controls in the Audio and Effects panels.

Closed and open Inspector group controls in the Fairlight page

FAIRLIGHT

These controls include:

- **Enable button:** A toggle control to the left of the parameter group's name lets you disable and re-enable every parameter within that group at once. Orange means that track's enabled. Gray is disabled.
- **Parameter group title bar:** Double-clicking the title bar of any group of parameters collapses or opens them. Even more exciting than that, Option-double-clicking the title bar of one parameter group collapses or opens all parameter groups at once.
- **Keyframe and Next/Previous Keyframe buttons:** This button lets you add or remove keyframes at the position of the playhead to or from every single parameter within the group. When the button is highlighted orange, a keyframe is at the current position of the playhead. When it's dark gray, there is no keyframe. Left and right arrow buttons let you jump the playhead from keyframe to keyframe for further adjustment.
- **Reset button:** Lets you reset all parameters within that group to their default settings.

TIP: You can make "granular" adjustments to virtual sliders by holding down the Option or Shift key while clicking in and dragging left or right within the numerical value field.

The Audio Tab

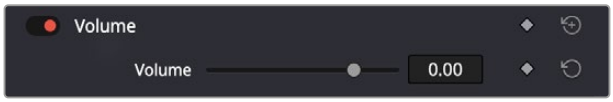
Clip Mode

When working with audio clips (Clip mode) on the Audio Timeline or Media Pool, the Audio tab offers the controls and audio effects described below.

NOTE: Parameters for audio clips on locked tracks cannot be edited in the Inspector. For more information on locking audio tracks, *see Chapter 172, "Editing Basics in the Fairlight Page."*

Volume

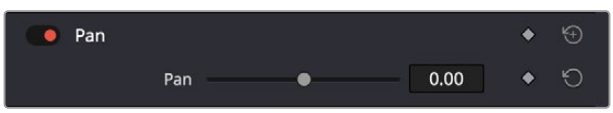
The Volume control that lets you adjust the gain of that clip.



Volume control in the Inspector

Pan

This control lets you pan a selected clip. While most professional mixes will restrict panning to the more robust panner found in the Fairlight page Mixer, this simple clip-based Pan control is useful for editors of visuals working in the Edit page to quickly create simple panning effects to aid in a craft edit. Dragging the slider lets you pan audio left to right. This control is centered at 0 by default.

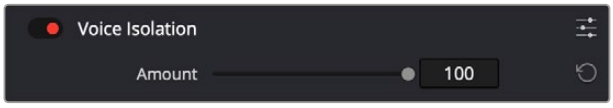


Pan control in the Inspector

Voice Isolation (Resolve Studio only)

When activated, this control applies Voice Isolation.

> For more information about Voice Isolation, *see Chapter 178, "Fairlight FX."*

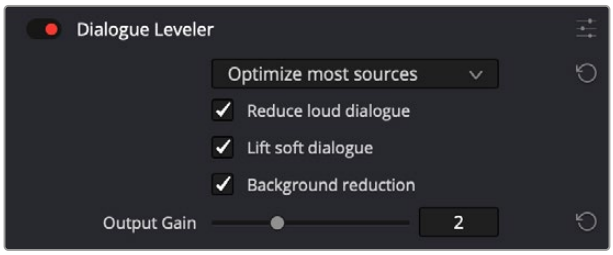


Voice Isolation control in the Inspector

Dialogue Leveler

Each audio clip in the Timeline or Media Pool has Dialogue Leveler controls that let you apply the effect to the clip.

> For more information about Dialogue Leveler, *see Chapter 178, "Fairlight FX."*



Dialogue Leveler controls in the Inspector

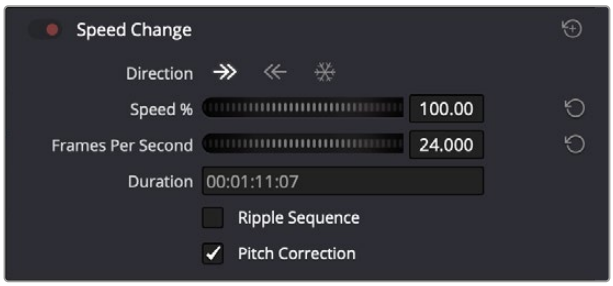
Pitch

The Pitch control lets you alter the pitch of a clip without changing the speed. Two sliders let you adjust clip pitch in Semi Tones (large adjustments, a twelfth of an octave) and Cents (fine adjustments, 100th of a semi tone).

Pitch control in the Inspector

Speed Change

The Speed Change control lets you alter the speed of the clip. It has the option to have the clip's pitch follow the adjusted speed change or maintain the original speed's pitch.



Speed Change control in the Inspector

The Speed Change window has the following overall controls:

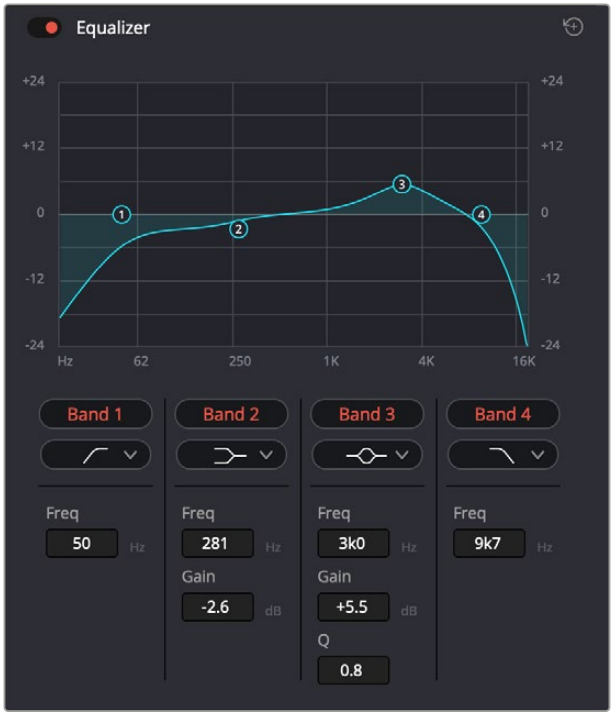
- **Enable button:** Turns the overall Speed Change effect off and on, without resetting the controls.
- **Reset button:** Resets all controls of the Speed Change window to their defaults.
- **Direction:** The Right Arrow maintains the forward direction of the waveform, the Left Arrow reverses the direction of the waveform, and the Snowflake icon creates a freeze frame.
- **Speed %:** A flywheel control to adjust the speed by a percentage plus or minus 100%.
- **Frames Per Second:** A flywheel control that syncs with the Speed % control showing the FPS relative to the speed change.
- **Duration:** Indicates the new timing of the clip.
- **Ripple Sequence:** When checked this moves all the media after the action to ripple edit to the new duration.
- **Pitch Correction:** When checked this maintains the original pitch of the clips when speed changed. When unchecked the audio will speed up or slow down with the speed adjustment. The slower the speed change, the lower the pitch; the higher the speed change, the higher the pitch.

NOTE: When in the Speed Change controls, do not use the freeze frame option. This will negatively affect the selected audio file.

Parametric Equalizer

This four-band equalizer has both graphical and numeric controls for boosting or attenuating different ranges of frequencies within that clip, before it even gets to the EQ built into the Mixer. Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band), with the available controls for each band of EQ changing depending on the filter type.

When a channel strip's EQ is enabled, the equalization curve that's being applied is displayed in the Mixer. A channel strip's EQ settings affect all the clips on that track, so you must open the EQ window to make those modifications.



The channel strip's EQ indicator

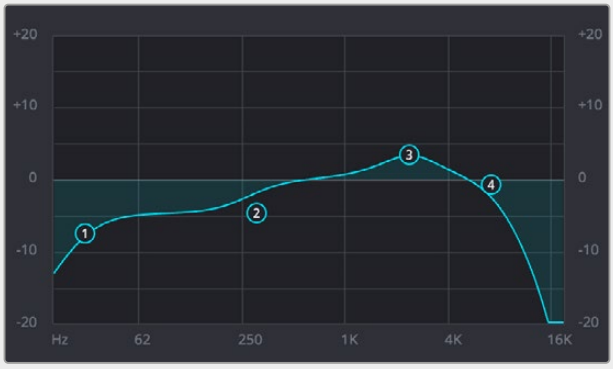
Master EQ Controls

The Equalizer window has the following overall controls located in the upper right and left corners.

- **Enable button:** Turns the overall EQ effect off and on, without resetting the controls.
- **Reset button:** Resets all controls of the EQ window to their defaults.

EQ Graph

This graph displays the current EQ curve with handles that correspond to each enabled EQ band listed below. You can drag any numbered handle to boost or attenuate the range of frequencies governed by that band, using whatever type of equalization that band has been set to.



The EQ graph with user-draggable handles

Dragging the numbered handles on this graph in turn modifies the parameters of the corresponding band, and changing each band's parameters will also alter the EQ graph, which serves the additional purpose of providing a graphical representation of the equalization being applied to that track.

Bands 1 and 4

The outer two sets of band controls let you make high-pass and low-pass adjustments, if necessary.

- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** Bands 1 and 4 can be switched among six specific filtering options for processing the lowest or highest frequencies in the signal. These include (from top to bottom): Hi-Shelf, Hi-Pass, Bell, Notch, Lo-Pass, and Lo-Shelf. Bands 2 and 3 can be switched among Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Freq:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are impacted. Negative values attenuate those frequencies, while positive values boost those frequencies.

Bands 2 and 3

The middle two sets of band controls let you make a wide variety of equalization adjustments.

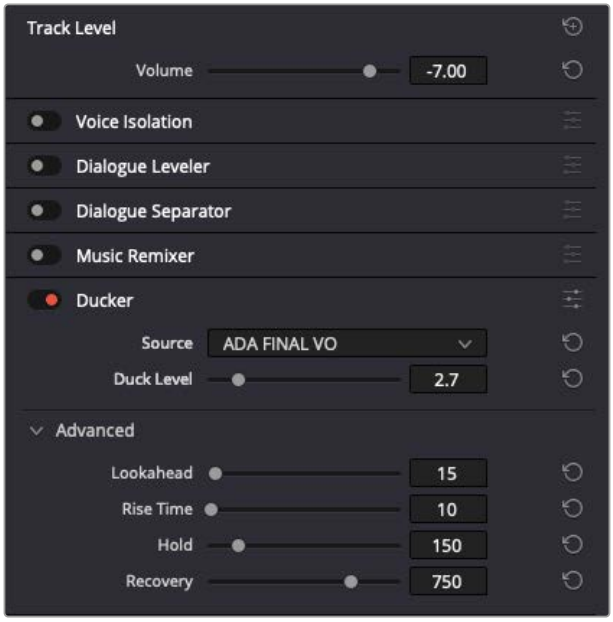
- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** Bands 2–5 can be switched among four different filtering options (from top to bottom): Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Frequency:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are affected. Negative values attenuate those frequencies, while positive values boost those frequencies.
- **Q Factor:** Adjusts the width of affected frequencies. Lower values include a wider range of frequencies; higher values include a narrower range of frequencies.

NOTE: This may seem obvious, but not all parameters are available for every curve type. For instance, a Bell curve filter has Frequency, Gain, and Q adjustments, but a Lo-Pass or Hi-Pass filter will only have Frequency available to adjust.

Track Mode

When working with audio tracks or busses (Track mode) the Audio tab lets you adjust the volume level and enable and adjust Fairlight Track FX.

For more information on Fairlight Track FX, *see Chapter 178, "Fairlight FX."*

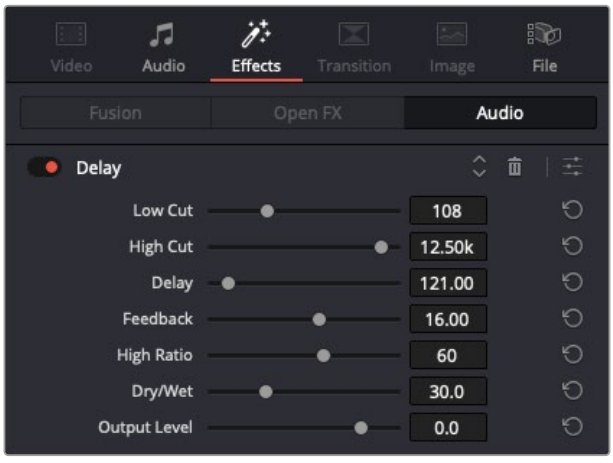


Audio tab - Track mode

NOTE: Parameters for locked tracks cannot be edited in the Inspector. For more information on locking audio tracks, *see Chapter 172, "Editing Basics in the Fairlight Page."*

The Effects Tab

Audio Effects added to a track or bus via the Effects section of its Mixer channel strip or to a timeline clip from the Effects Library will appear in this tab.

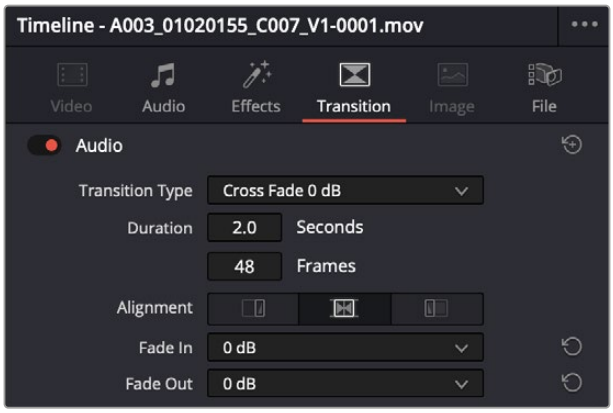


Fairlight FX Delay controls in the Effects tab

For more information, *see Chapter 177, "Audio Effects."*

The Transition Tab

If you've applied any Transitions (Crossfade) between clips in either the Edit or Fairlight pages, you can adjust them in the Transition tab, which can be opened by double-clicking a Crossfade transition.



Crossfade controls in the Transition tab of the Inspector

The following properties can be edited:

- **Transition Type:** The currently selected transition. You can change to any other installed transition by selecting one in the dropdown menu.
- **Duration:** The duration of the transition, shown in both seconds and frames.
- **Alignment:** A dropdown that lets you choose the transition's position relative to the edit point it's applied to. Your choices are "Start on Edit," "Center on Edit," and "End on Edit."
- **Fade In:** This dropdown offers selection from -3dB to 3dB.
- **Fade Out:** This dropdown offers selection from -3dB to 3dB.

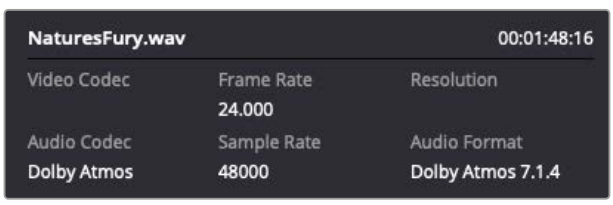
For more information on adjusting crossfades, *see Chapter 172, "Editing Basics in the Fairlight Page."*

The File Tab

The File tab includes different sections where you can view or edit the properties and configuration of audio clips on the Timeline and in the Media Pool.

File Information

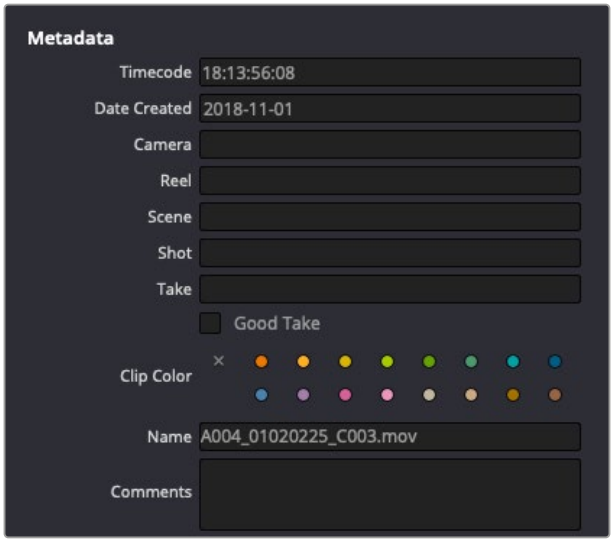
In addition to the name of the audio clip, this section of the File tab provides additional details about the file, as shown in the screenshot below.



File tab - File Information section

Metadata

Except for the embedded Timecode field, every text field can be edited with information of your choice.

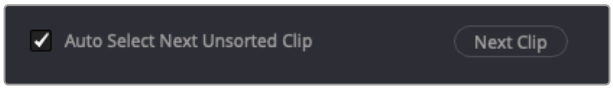


File tab - File Metadata section

Auto Select Next Unsorted Clip

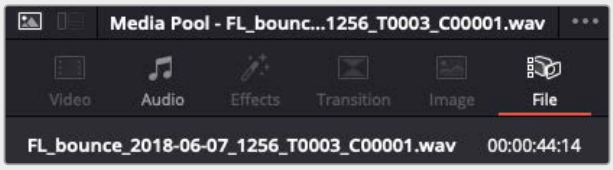
When this box is checked, pressing the Return key after filling in a metadata field selects the next Media Pool clip with the cursor in the same field.

This allows rapid sequential metadata entry without clicking the Next Clip button or manually clicking the next Media Pool clip.



Auto Select Next Unsorted Clip checkbox and Next Clip button

Whenever a Media Pool clip is selected, the name displayed to the right of the Clip and Track and Mode buttons will begin with “Media Pool – “.



File tab - Media Pool clip selected

Audio Configuration

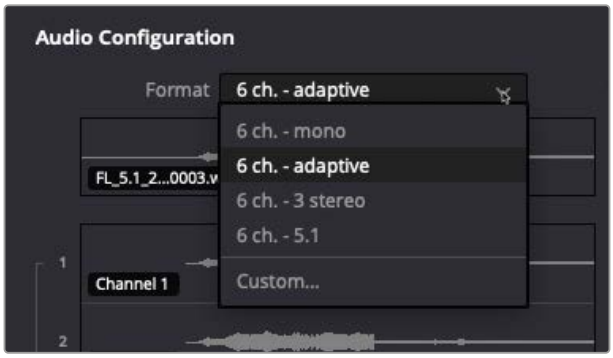
This section of the File tab includes features and controls that let you intuitively change an audio clip's channel properties. These changes determine the number of active channels in the clip and their individual source and volume levels when inserted into the Timeline.

The appearance of the Audio Configuration pane will vary depending on the format of the clip you're trimming. For example, the screenshots below depict a 6-channel clip in the Media Pool in two different channel formats.

6-channel adaptive - Media Pool clip

6-channel mono - Media Pool clip

- **Format:** When an audio clip is selected in the Media Pool, the Format dropdown displays its current channel format, standard channel configurations, and a Custom option. You can apply these channel configurations to the clip without having to use the Clip Attributes to customize the clip.



Format dropdown menu - for a 6-channel adaptive clip

When a timeline clip is selected, the Format dropdown displays its current channel format and the Custom option. However, the timeline clip is comprised of two mono channels; it is possible to change the audio sources for each channel.

Choosing the Custom option opens the Audio tab of the Clip Attributes dialog.

For more information on using the Clip Attributes dialog, *see Chapter 22, "Modifying Clips and Clip Attributes."*

- **Waveforms:** When working with a Media Pool clip, the first waveform beneath the Format dropdown displays a composite of all channels within the audio file. The remaining waveforms represent the audio content of each channel within the clip.

  The composite waveform is not available when working with timeline clips.

  You can listen to the audio by skimming it with your mouse cursor, clicking the Play button in the transport control below the last waveform, or pressing the spacebar.

  If you click anywhere within any waveform, playback will continue playing the audio from that point. This concept is explained in more detail in the Transport Controls section below.

- **Channel Controls:** When working with source clips in the Media Pool, each clip channel has its own Enable/Disable checkbox and Mute button.
- **Active/Inactive:** Filling in the checkbox enables the channel, making it active and available for editing operations. Conversely, when the checkbox is empty, the channel is unaffected by editing operations, as if it were removed from the clip.

  Using the example of a 6-channel mono clip in the Media Pool, if you deactivate channel 2, only five tracks (1, 3, 4, 5, and 6) will be included when it's dragged from the Media Pool to the Timeline.

6 mono channel Media Pool clip

- **Mute:** Clicking this button mutes the channel while leaving it in place within the clip. So, in the case of the six-channel Media Pool clip, if you filled in the checkbox for channel two and then activated the Mute button, all six channels will be included when the clip is dragged onto the Timeline, but only channels 1, 3, 4, 5, and 6 will be audible.

TIP: Option-clicking a Mute button or Active/Inactive checkbox toggles all others to the opposite state, effectively soloing the channel you are interacting with.

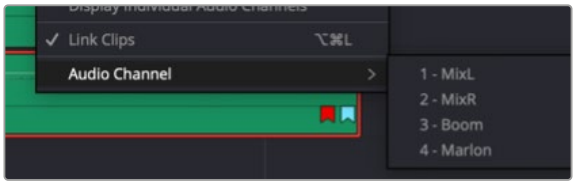
- **Channel Source:** When working with multichannel clips comprised of all mono channels, the Audio Configuration pane will include a dropdown displaying the name of the current audio source of each waveform. Clicking the dropdown lets you choose from a list of mono audio sources.

  This is useful if, for example, you need to change the signal for a person's lavalier mic to another or the boom mic channel has a loud noise because it was bumped during a take and needs to be changed to another source.

Audio Channel Source menu

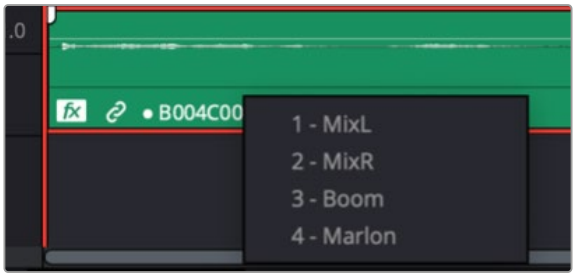
Changing the Channel Source on the Timeline

To change an audio source on the Timeline, right-click the audio channel you need to correct and select an option from the list at the bottom of the contextual menu.



Audio Channel Source menu - Timeline menu

A quicker way to access these options is to Command right-click the audio channel in question.



Audio Channel Source menu - Simplified Timeline menu

- **Transport Controls:** Once the playback has been started using the Play button, clicking anywhere within a waveform effectively "solos" that channel and continues playing the audio from that point.

  If you are working with a Media Pool clip, clicking anywhere within the composite waveform lets you hear the mix of enabled and unmuted channels from that point.

  When working with a timeline clip, you can switch to hearing all channels by clicking the Stop button followed by the Play button.

- **Level:** This control becomes active once one or more channels are selected and is used to trim the level of individual channels of multichannel Media Pool or timeline clips.

This feature can be helpful when one or more channels aren't loud enough and needs to be trimmed to match the other channels.

Trim adjustments made within timeline clips are independent of their clip gain and do not affect their corresponding Media Pool clip.

> **TIP:** Command or Shift-clicking to select multiple channels lets you simultaneously trim all channels in that selection. However, it's important to note they will all be trimmed by the same amount (in dB).

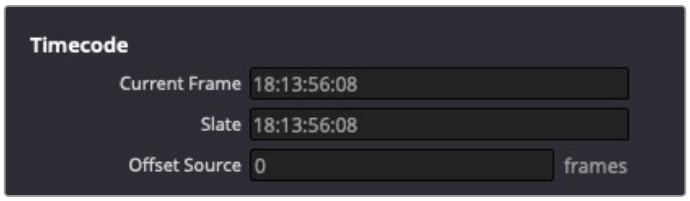
Adjusting Multiple Clips in the File Tab

You can select multiple audio clips and adjust their properties in the Audio Configuration pane. For example, you can select a group of audio files and remove Track 2 from all of them at once. However, the following should be noted:

- In a multiple clip selection, only the last selected clip will appear in the track layout of the Audio Configuration Pane. However the top composite waveform will be named "Multiple Clips" to let you know that more than one clip has been selected.
- Any adjustments, like muting or enabling/disabling a track will be applied to all the selected clips at once.

Timecode

This pane includes controls that were formerly handled by Clip Attributes in the Media Pool (though that option is still available). These controls let you override the timecode details for a clip or clips in the Media Pool.



File tab – Timecode section

- **Current Frame:** This is where you can assign a new time for the timecode at the currently viewed frame of the clip.
- **Slate:** In situations where source media comes from a shoot where a timecode slate was used during the shoot, then you can assign the slate timecode as a second timecode track that can be used for various operations without changing the primary timecode of the clip, which may already be in use for program sync.

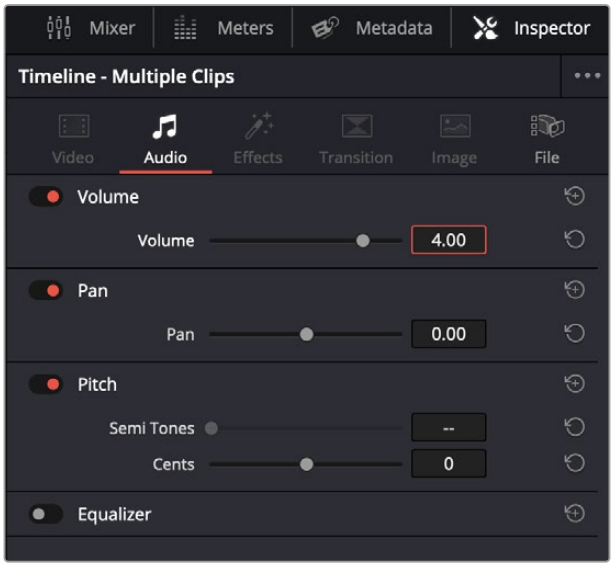
  To set the appropriate Slate timecode, select a Media Pool clip with a visible timecode slate and move the playhead to a frame where the timecode in the slate is clearly readable. Then, open the Timecode panel of the Clip Attributes window and type the timecode value you see in the image into the Slate Timecode field.
- **Offset Source:** If an entire set of clips has timecode that's merely offset, you can correct the timecode offset for as many selected clips as you like.

Adjusting Multiple Clips Simultaneously

There's an easy way to make adjustments to the Inspector parameters of multiple clips at the same time, without needing to use Paste Attributes (described later in this chapter). All you need to do is simultaneously select every clip you want to alter, and then modify the parameter in the Inspector that you want to change. As a result, every selected clip will be adjusted by the same amount. This works for compositing effects, transforms, text parameters, filters, and audio settings, just about anything that can be simultaneously exposed in the Inspector for multiple selected clips.

When you select multiple clips, the Inspector will display "Multiple Clips" as the title. If each of the selected clips have different values in the parameter you're adjusting, that parameter will have two dashes in the value field. There are two ways you can make adjustments to multiple clips:

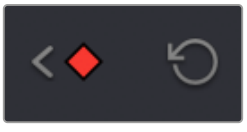
- If you want to make a relative adjustment to all selected clips while keeping their original offsets from one another, then drag the virtual slider in the parameter field which will display a + or – before however many units your adjustment is.
- However, if you want to set all selected clips to the same value, you can double-click in the number field, type the value, and press Return.



Making a relative adjustment of plus 4.00 in the Volume level of all selected clips

Animated Inspector Adjustments

Key-framing in the Edit page works slightly differently than when using the Keyframe Editor in the Color page. Most simple key-framing tasks can be performed in the Inspector using three buttons that appear to the right of any parameter that's capable of being keyframed. It takes two keyframes at minimum to create an animated effect.



The three keyframe controls that appear in the Inspector, from left to right: Previous keyframe, Create/ Delete keyframe, Next keyframe

Methods of key-framing parameters in the Inspector:

- **To add a keyframe:** Select a clip, open the Inspector, then move the Timeline playhead to the frame where you want to place a keyframe, and click the Keyframe button next to the parameter of the Inspector you want to animate. Once you've added at least one keyframe to a parameter, all other adjustments you make to parameters in the Inspector, or using the onscreen Transform/Crop controls in the Timeline Viewer, add new keyframes automatically if the playhead is at another frame.
- **To move the playhead to the next or previous keyframe:** Click the small left- or right-hand arrow to either side of a parameter's keyframe control to jump the playhead to the next or previous keyframe. You can also press Right-Bracket ([ ) and Left-Bracket ( ]) to go from keyframe to keyframe.
- **To edit an existing keyframe of a parameter:** Move the playhead to be on top of the keyframe you want to edit, and then change that parameter, either in the Inspector, or using the onscreen controls of the Timeline Viewer.

Methods of changing keyframe interpolation in the Inspector:

- **To change a keyframe to Ease In or Ease Out:** Eased keyframes create animated changes that begin slowly and accelerate to full speed, or slow down gradually to decelerate to a stop. This only works when you have two or more keyframes creating an animated effect. Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose Ease In, Ease Out, or Ease In and Out, depending on which keyframe you're editing and the effect you want to create.
- **To change a keyframe to Linear:** Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose Linear.

Methods of deleting keyframes and disabling keyframed effects:

- **To delete a single keyframe:** Open the Inspector, move the Timeline playhead to a frame with a keyframe, and click the orange Keyframe button in the Inspector to delete it.
- **To delete all keyframes for one parameter:** Click the reset button to the right of a parameter's keyframe control in the Inspector.
- **To delete all keyframes in a group of parameters in the Inspector:** Click the reset button to the right of a parameter group's title bar in the Inspector.
- **To disable or enable a single parameter's keyframed effect:** In the Timeline, click the toggle control at the left of a parameter's keyframe track. Orange means that track's enabled. Gray is disabled.
- **To disable or enable a group of parameters in the Inspector:** Click the toggle control at the left of a parameter group's title bar in the Inspector. Orange means that group is enabled. Gray is disabled.

Paste and Remove Attributes

The Fairlight page has Paste Attributes and Remove Attributes commands that allow for the copying and resetting of audio Inspector parameters and effects, similar to the same commands on the Edit page.

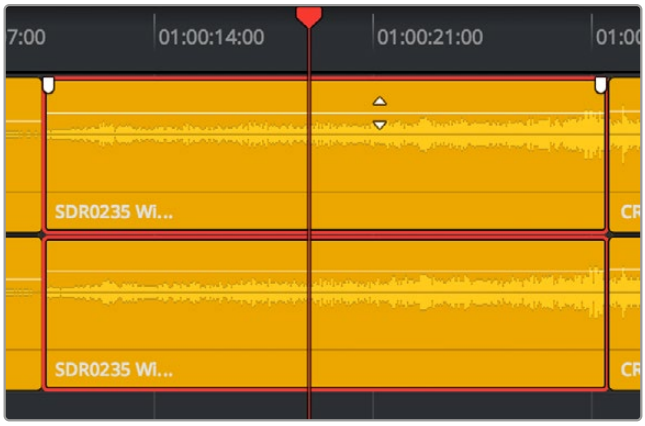
For more information on how to do this, *see Chapter 172, "Editing Basics in the Fairlight Page."*

Setting Clip Volume in the Timeline

Each audio clip, or audio item in the case of audio clips with linked audio on multiple tracks, has its own Volume level. This means that audio clips with multiple channels share a common Volume setting. There are several ways you can adjust these levels simply.

Adjusting Volume

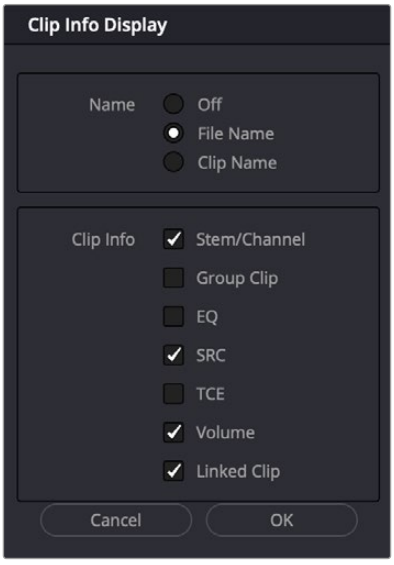
Each clip (or item) of audio in the Timeline has a Volume overlay that lets you set that clip's gain level by simply dragging it up or down with the pointer. This overlay corresponds to the Volume parameter in the Inspector.



Dragging a Volume overlay to adjust the clip level

Additionally, you can click any clip's Audio Curve Editor button, at the bottom right-hand corner of each audio clip, to open an audio-specific Curve Editor with which you can keyframe not just volume, but pan, and the parameters of any audio filters you might have applied to that clip.

NOTE: Under the Fairlight menu > Show Clip Gain Line, you can show each clip's gain in the Timeline. This is a handy way to quickly see all of the relative gains of clips in the Timeline.



Clip information for all clips in the Timeline can be enabled in the Clip Info display.

Adding and Adjusting Volume Keyframes

Mixing audio by adding and adjusting individual keyframes can be a fast and effective way of balancing clip levels with one another and of fixing clip-specific dynamic level problems. When manually editing any audio parameter curve, you can use the following procedures.

Methods of adjusting the Volume curve using the pointer:

- **To adjust any curve segment:** Position the pointer over the overall segment for clips with no keyframes, or position it between any two keyframes, directly on top of the curve segment you want to raise or lower. When the move cursor is displayed, click and drag up to raise the Volume, or down to reduce the Volume.
- **To adjust a section of level in a clip:** Use the Edit Selection tool to highlight the portion to adjust. Then with the Clip Gain line showing, increase or decrease to the desired level and keyframes will automatically be created at the boundary of the gain adjustment.
- **To add keyframes to the level curve:** Hold the Option key down and click the curve to place a keyframe at that frame. You must add at least two keyframes to create an automated change in Volume. By using the Option and Command key you can remove any keyframe.
- **To adjust a keyframe in any direction:** Move the pointer over a keyframe so that the four-way cursor appears, and then click and drag up or down to change the Volume, or side to side to change its timing.
- **To adjust a keyframe in only one direction:** Move the pointer over a keyframe so that the four-way cursor appears, and then click and drag in the intended direction of adjustment, either vertically to change the volume of the clip at that frame, or horizontally to move the keyframe to a different point in time. Once you start dragging a keyframe into a particular direction, keyframe movement is constrained in that direction until you release that keyframe.
- **To select one or more keyframes:** Click any keyframe to select it.
- **To select multiple discontiguous keyframes:** Command-click all keyframes you want to select, whether they're next to one another or not.
- **To select multiple contiguous keyframes:** Click the first keyframe you want to select, and then shift-click the last keyframe you want to select, and all keyframes between will also be selected.

NOTE: When adjusting the gain on clips, the tooltips will show the current gain level and reflect whatever changes you make indicating the amount of change as the keyframe moves.

Normalizing Audio Levels

The Normalize Audio Levels command automatically adjusts the level of timeline clips to a specific target level, and you can choose the method used to analyze each audio clip's levels to determine how to normalize each clip's volume. Options include a variety of loudness normalization algorithms specific to various international standards, which are useful for balancing the perceived overall loudness of several clips to one another, regardless of transient levels throughout each clip. You can also do Peak normalization, with options for both Sample Peak and True Peak.

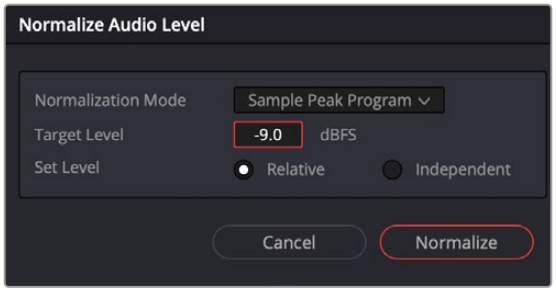
The various loudness options are designed to analyze an audio signal based on its perceived loudness to the listener, which results in a more accurate automatic balancing of different clips' audio levels to one another, regardless of transient peaks occurring throughout different clips.

The target peak meter now uses the BS.1774 standard for measuring maximum "true peak," which means that this meter is capable of measuring "inter-sample peaks," rather than only the peaks at each sample of a waveform. However, you still have the option to measure Sample Peak, which is the previous method of measuring the actual peak of the samples in a media file.

The change made by the Normalize Audio Volume command is only a volume adjustment; no dynamics are applied, so the result of using this command is that the loudest parts of each selected clip are going to match one another at the target level. This command is also available in the Fairlight page.

To normalize one or more selected timeline clips:

1 Right-click one of the selected clips and choose Normalize Audio Levels. The Normalize Audio Level dialog appears.



The Normalize Dialog in the Fairlight page

2 Choose the Normalization Mode you want to use. You can choose among a variety of standardized loudness measurement algorithms, or Sample Peak, or True Peak.

3 Choose the reference level that you want to set the peak volume of the selected clips to match, in dBFS.

4 Choose how you want to set the level of multiple selected clips:

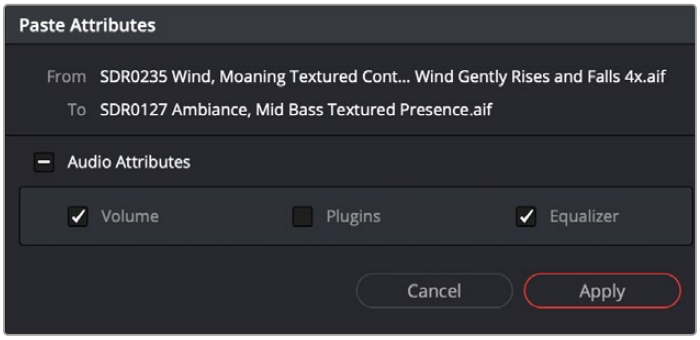
When Set Level is set to Relative, all selected clips are treated as if they're one clip, so that the highest peak level of all selected clips is used to define the adjustment, and the volume of all selected clips is adjusted by the same amount. This is good if you have a series of clips, such as a dialog recording, where the levels are consistent with one another, and you want to normalize all of them together.

When Set Level is set to Independent, the peak level of each clip is used to define the adjustment to that clip, so that the volume of every selected clip is adjusted by an amount specific to that clip. The end result may be a set of very different volume adjustments intended to make the peak levels of each audio clip match one another. This is good if, for example, you're trying to balance a series of different sound effects with one another that have very different starting levels.

For more information about loudness normalization, *see Chapter 179, "Audio Meters and Audio Monitoring."*

Paste and Remove Attributes for Clips and Tracks

The Fairlight page has Paste Attributes and Remove Attributes commands that allow for the copying and resetting of audio parameters and effects, similar to the same commands on the Edit page.



The Paste Attributes dialog in the Fairlight page

The Paste Attributes dialog box gives you three types of attributes to choose from. Volume will paste the copied attributes to the clip. Plugins will paste any plugin attributes to the clip. Equalizer will past EQ data copied from another clip. One or all of these can be copied at one time.

The Remove Attributes dialog box gives you the same three types of attributes to choose from for removal of a clip. When the Volume box is enabled, all Clip Gain keyframes will be removed from the clip.

Chapter 174

Mixing in the Fairlight Page

The Mixer is “control central” of the Fairlight page, providing all of the functionality you need to mix the various audio tracks of your program into a harmonious whole.

By using EQ, dynamics, panning, level control, and Fairlight FX, VST and Audio Units audio plugin effects of all kinds, all with full automation, you can hone your sound and balance each track’s elements with one another.

This chapter focuses on explaining the various functions of the Mixer so you can harness its power for yourself.

Introduction to Mixing

This chapter describes how to use the Mixer to adjust the levels and fine-tune the audio of each track in the timeline. It's focused on the function of the channel strip controls, with the following exceptions:

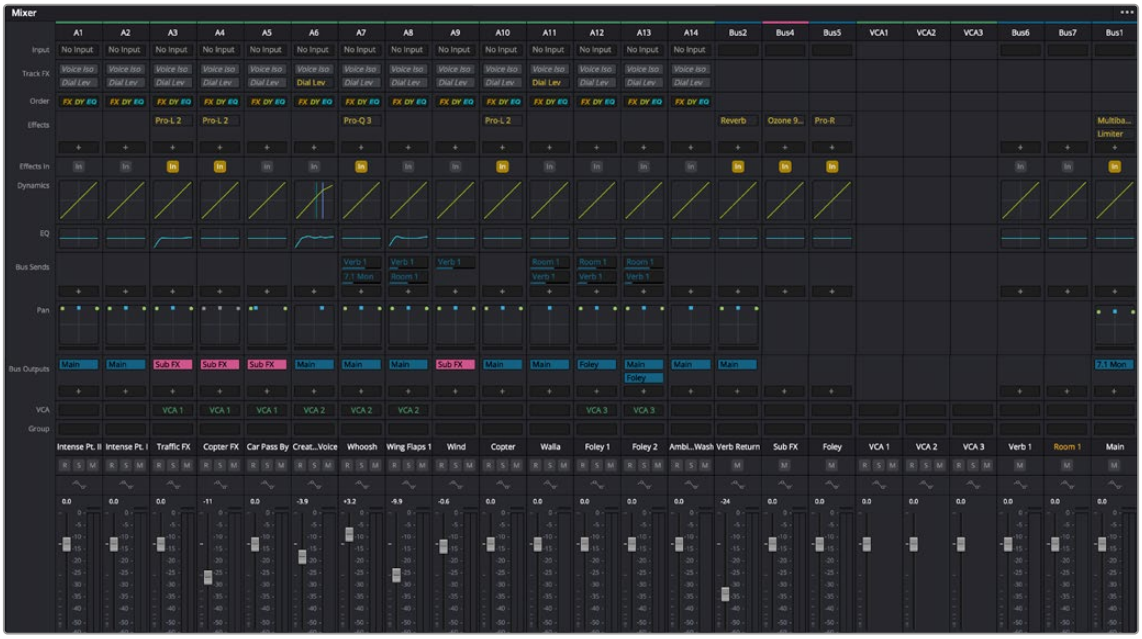
For more information about bussing, *see Chapter 168, "Setting Up Tracks, Busses, and Patching."*

For more information about recording audio, *see Chapter 170, "Recording."*

For more information about mix automation, *see Chapter 175, "Mix Automation."*

The Mixer

The Audio Mixer provides a set of graphical controls you can use to assign track channels to output channels, adjust EQ and dynamics, set levels and record automation, pan stereo and surround audio, mute and solo tracks, and add Fairlight FX, or VST, or AU effects plugins. At its most basic, each audio track in your timeline corresponds to an individual channel strip in the Mixer, and by default there's a single main stereo mix bus labeled "Bus 1" that combines all these tracks into an overall mix.



The Audio Mixer with channel strips corresponding to the tracks in the Timeline

Tracks and Busses

Once you start creating busses, the Audio Mixer exposes two sets of channel strips. The leftmost set of channel strips correspond to the audio tracks in the Timeline, while the right-most set of channel strips expose sets of controls for each bus that you've created.

By default, the Audio Mixer is divided into two sections, one for tracks (at left) and one for busses (at right).

If you have more tracks and busses than can be displayed all at once given the width of your computer display, then each half of the Mixer has independent scroll bars so you can choose which tracks and which busses you want to see next to one another. You can also remove the split between sections and have a single, continuously scrollable view with all tracks, or change the order or split point for the channels.

FlexBus Routing and Mixing

The Fairlight audio engine bussing system is called FlexBus. As its name suggests, FlexBus offers a hight level of flexibility for bus types and signal routing. DaVinci Resolve Fairlight's older Fixed Bus configuration (prior to DaVinci Resolve v17) offered a more limited fixed bus topology, and can still be used, but FlexBus makes it possible to patch outputs and/or sends in any way required, as dictated by your project.

With FlexBus, each track can output to up to ten busses and sends with additional level and pan controls to a further ten busses. Busses can be sent to other busses up to six layers deep, facilitating complex stem building, processing, and allowing discrete deliverables.

For more information, *see Chapter 168, "Setting Up Tracks, Busses, and Patching."*

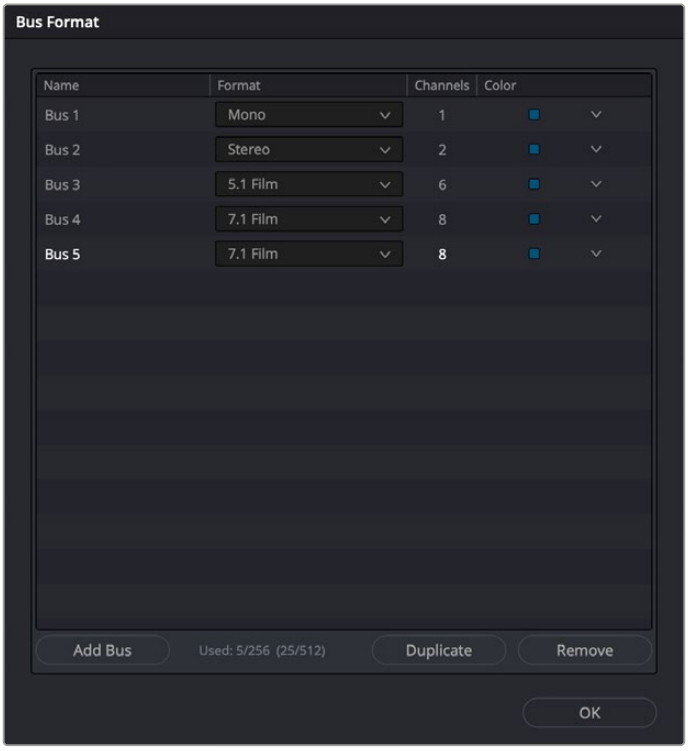
What is a Bus?

A bus is simply a common signal connection point in an audio mixer. Busses can be mono, stereo, or any larger format, like 5.1 or Dolby Atmos 9.1.6 (where 16 audio signals are used). Bussed connections are mix points for the audio, allowing each audio track feeding their signals to the bus to be summed together to create a master output for that bus.

Bus-to-Bus Routing

A mix may use a single bus (for example, the default stereo Main 1 bus may be all that you need if you're doing basic stereo mixing). Or you can create "submixes" where multiple busses feed into other busses to create a master mix. For example, you might have a dialogue bus, an effects bus, and a music bus so you have control over those elements separately via the bus "masters" for each, then feed the 3 masters into a main output bus for final mix rendering.

You may want to route the output of a bus to an audio track to record the resulting signal, or route to monitor speakers to listen to the real time output. Finally, the Deliver page can render the output of your designated master bus to create a final bounced file.



The FlexBus structure allows for many different bus track types to be createdμ or changed.

User-definable busses allow for bus-to-bus, bus-to-track, or track-to-bus routing, with each bus having the ability to sum together signals from mono to fully immersive formats (such as Dolby Atmos and Ambisonics) at your discretion. As with any and all of the audio track types in Fairlight, you can change bus types at any time if needed.

The power of the FlexBus system is that it allows you to direct signals to many different places at one time to achieve complex mixing scenarios. Perhaps you need to generate two mixes that are identical in content but need to be of different output levels. You can designate two mix busses, one with a target output level of -14 LUFS and one with a target output level of -24 LUFS. The final mix signal is sent to one bus that is then broken into two more busses, one with a limiter set to accommodate the -14 LUFS mix and one set to the correct level for the -24 LUFS mix, allowing you to create these two different mixes at one time.

In Ambisonic workflows, you can route an Ambisonic bus to another Ambisonic bus, even with differing orders, and any required up- or down-mixing is automatically handled by the Fairlight engine and FlexBus.

FlexBus supports expanded Dolby Atmos capabilities and Ambisonics; for more information *see Chapter 181, "Immersive Audio Workflows."*

FlexBus bus routing buttons

Legacy Fixed Bussing

Prior to DaVinci Resolve 17, the Mixer had a fixed topology with specific, fixed numbers of sends, submix busses, and main outputs. DaVinci Resolve still supports this older “legacy” bussing topology to maintain compatibility with earlier projects.

With the current FlexBus bussing, the Mixer looks slightly different. The Aux panel on the legacy Mixer has been renamed Bus Send, and the Main/Submix panel has been changed to Bus Outputs.

In the legacy Fixed Bus view:

- Each audio track’s channel strip has a set of Main and Submix bus buttons that let you assign the audio output by that channel strip to a Sub (typically used to combine different subsets of tracks into submixes) or to a Main (typically used to output or render overall mixes).
- Each Sub and Aux’s channel strip has a set of Main buttons so that different combinations of Subs can be assigned to each Main. Main channel strips have no buttons because, from a bussing perspective, they’re the final output.
- Main and Submix buttons let you assign tracks to busses, and busses to other busses.

Main and Submix bus buttons

Using Legacy Fixed Busing

If you want to work using the previous method of Fixed Bus mapping, you can do so for new projects by accessing the Project Settings > Fairlight panel, and turning on the “Use fixed bus mapping” checkbox. However, as there is no practical advantage to using the older legacy fixed bus system, and several features are only available in FlexBus, using FlexBus is recommended.

Converting Older Fixed Bus Projects to FlexBus

Older Fixed Bus projects can be converted to FlexBus by doing the following:

- Open Project Settings > Fairlight.
- Under the Bussing heading, uncheck “Use fixed bus mapping.”
- A dialog will appear, allowing you to convert the project to FlexBus.

Customizing the Onscreen Mixer Controls

The 3 dot Option menu at the upper right-hand corner of the Mixer provides several different options for customizing the appearance of the Mixer, as well as which controls are shown or hidden:

- **Full Track Mixer or Small Track Mixer option:** While the Full Track Mixer provides more room for buttons and controls that are large enough you don't have to squint to see them, the Small Track Mixer allows many more channel strips to be seen at one time.

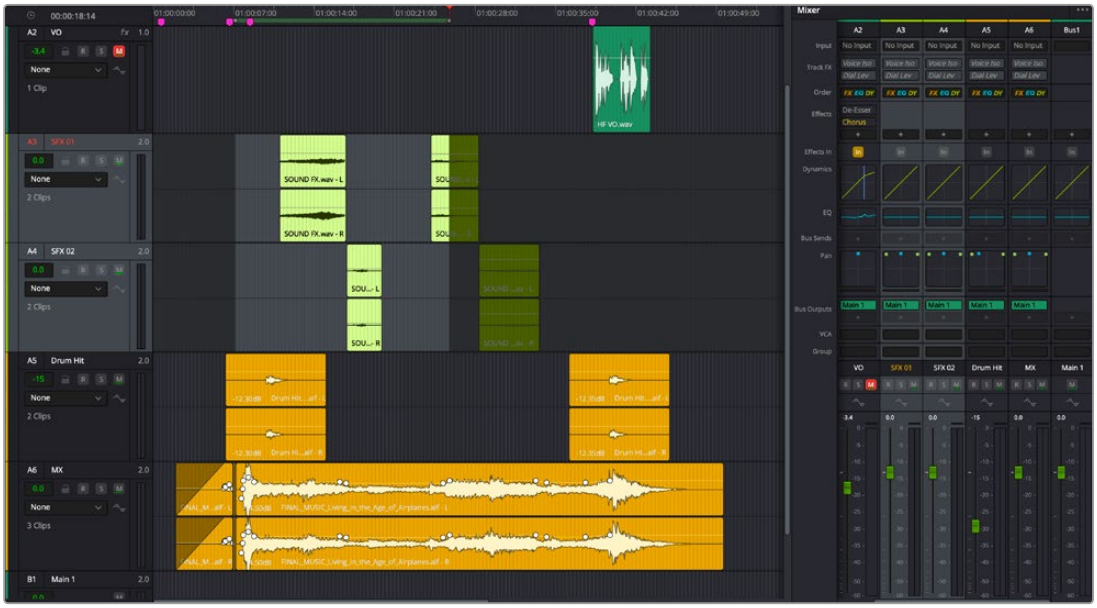
The Small Track Mixer view

- **Show Labels option:** These are the sectional names for functional areas of the Mixer that appear at the far left of the Mixer channel strip area. If you're first getting started, these labels are useful, but once you've gotten used to the Mixer's layout, hiding the labels can give you a bit more room to work with for another channel strip or two.
- **Channel Strip Control Visibility options:** Allows controls to be shown or hidden in the Mixer. You can hide controls you know you're not going to be using, no longer need to adjust, or wish to not disturb.

Selecting Channel Strips and Tracks

When you select a track in the Timeline, you also select that track's accompanying Mixer channel strip, and vice versa:

- To select single tracks, just click.
- To select multiple contiguous tracks, select a starting track or channel strip, hold down Shift, and click on last item you want in your selection.
- You can also select multiple channel strips in the Mixer by clicking and dragging to create a bounding box around the tracks you want to select.
- To select non-adjacent (discontiguous) tracks or channel strips, command-click on each item you want to add to your selection.



Selecting multiple channel strips selects the same tracks in the Timeline

Track Organization

Each channel strip has three organizational properties that let you keep track of which channel strip is responsible for which part of the mix.

- **Track color:** Each track can be differently color coded to help you keep organized. These colors appear in the Timeline track header, the Mixer, and the meters to help you keep track of which track corresponds to which channel strip and meter.

The track color and track number appear at the top of each channel strip.

- **Track number:** The number of the timeline audio track corresponding to each channel strip appears here.
- **Track name:** This mirrors the track name found in the track header of a track on the Timeline. If you customize an audio track's name in the Timeline or in the Mixer, that name appears here.

Each track's name appears between the assignment buttons and the arm/solo/mute buttons

Rearranging Tracks

You can reposition your tracks and busses in the Mixer by clicking and holding the track name and dragging left or right to the desired location. This works for both individual and selection of multiple channel strips.

Rearranging tracks by moving a Mixer channel strip

As you move your mouse, a white line will appear indicating the new location and the change will be reflected in the Index.

Disabling Tracks

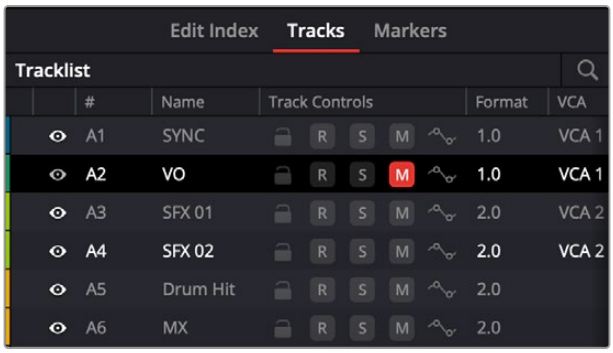
You can disable an audio track in the Mixer by right-clicking the track number at the top of the corresponding channel strip and choosing Disable Track from the contextual menu. Repeating these steps will re-enable the track.

Disabling multiple tracks via the Mixer

To simultaneously disable multiple tracks, select them, Option right-click any track number in the group, and choose Disable Tracks from the contextual menu.

Managing Channel Strips Using the Index

The Index is a consolidated list view of all the tracks in the current Timeline, designed to make it easier to manage timelines with lots of tracks. Columns let you see each track's visibility, track number, name, controls, channel format, monitor assignment (if any), ADC controls, and VCA assignment. The controls in these columns let you manage the tracks in the current Timeline by showing or hiding them, toggling track controls, or rearranging them. You can also right-click on one or more selected tracks to color code them, or change the track type.



The Tracks panel of the Index shows all tracks on both the Timeline and the Mixer.

Showing and Hiding Tracks

You can use the Tracks panel of the Index to hide tracks you don't need to work on in order to create more room for tracks you need to see.

> **TIP:** To quickly show or hide a number of tracks, click and drag up or down over the eyeball button of each track where you want to toggle the visibility.

Color Coding Tracks

Select one or more tracks, then right click one of the selected tracks and choose a color from the Change Track Color submenu of the contextual menu.

Toggling Lock, Record, Solo, and Mute

As with visibility, you can use the Lock, Record, Solo, and Mute controls to quickly enable or disable multiple tracks by clicking and dragging up or down over the Lock, R, S, or M buttons you want to toggle.

Rearranging Tracks

You can rearrange tracks in the Tracks tab in the Index by clicking any track strip area between other controls, and then dragging that track up or down in the Index. As you drag, a white line shows you where that track will be inserted when you release it. You can even select a contiguous series of tracks and drag them all to a new position in the Timeline at once.

Managing the Dividing Line

By default, there are two areas of tracks in the Index; one area is for audio tracks, and one area for busses and VCAs with a dividing line separating them. Busses and VCAs can be dragged up out of the divider and into any position for any order. This can be quite useful when having a series of dialogue tracks, for instance, and pulling the dialogue bus up next to them.

The dividing line's position can be moved to any location by dragging it, so you can keep the split organization of tracks into two different areas but re-order what is shown.

Once the order has been changed in the Index, this is reflected in both the Mixer panel as well as in the Meter panel. By reordering busses and tracks, you can adjust your workflow for whatever set of tasks you are working on.

Single Mixer View

Clicking the three-dot Option menu at the top of the Mixer panel offers an option for Single Mixer view. The Single Mixer view removes the divider line from the Tracks tab in the Index entirely, providing a continuous scroll of the tracks, both in the Mixer panel horizontal scroll and the Index vertical scroll. You can restore the divider at any time.

NOTE: You can reset the bus order to its original layout by choosing "Reset Bus Order" from the three-dot Options menu on the upper right of the Mixer.

Changing Track Type

Track type refers to the channel width of the audio track and what format it is. The track type can be changed at any time. For example, you could have a mono track and change it to a stereo, or 5.1 track, or a 12 channel adaptive.

To change the track type, select one or more tracks, then right-click one of the selected tracks and choose a different track type from the Change Track Type submenu of the contextual menu.

NOTE: Keep in mind that if you change from a larger track type to a smaller one, you may need to also set which of the channels in the larger source audio file are now audible on the smaller track type. This can be handled via the contextual menu choice Clip Attributes for a clip, using the Audio tab.

Deleting Tracks

You can delete an individual track by right-clicking it and choosing Delete Track from the contextual menu.

To delete multiple selected tracks simultaneously, right-click any track within the collection and choose Delete Tracks from the contextual menu.

Fairlight Mixer Signal Path

The signal path or layout (“topology”) of a mixer describes how the audio signals are routed from one place to another.

The default signal flow on the Fairlight channel strip is as follows:

1. Audio source: Input menu allows choice of source, including file playback, bus, live input, etc.
2. Path Settings: Accessible from the Input menu. Allows adjustments to the input signal.
3. Track FX: Built-in effects, Voice Isolation (Studio only), and Dialogue Leveler. Disabled by default.
4. Effect: Fairlight FX, AU, or VST effects.
5. Dynamics: Dedicated channel dynamics processor with expander/gate, compressor, and limiter.
6. EQ: Dedicated 6 band EQ with variable gain, frequency, and Q.
7. Output Routing: Panning and bussing.

The main fader for the channel strip then controls the level to any assigned main output busses. Bus Send faders control the level to any destination set for a mixer channel send and can be set pre-or post-fader.

What Is An Effects Insert?

Each time you add an effect to a channel, a signal processing “insert” (insertion point) is enabled. The source signal flows from the input of the effect to its output, and then onwards to any additional insert(s) to the next stop in the Mixer’s signal flow.

DaVinci Resolve supports a total of six inserts per channel in addition to the built in Dynamics and EQ processing.

Click on the Input area to access the Input dropdown menu, letting you patch inputs, patch busses, and configure the input settings of audio signals routed through Blackmagic or other hardware audio interfaces.

“Pre” vs. “Post”

The term pre refers to a signal that is routed for use before another connection point. For example, you may prefer to work with pre-fader metering as you can always see the original signal level coming off of disk reflected in the meter level.

A signal that is post occurs after a connection point. For example, you generally want effect sends that go to a reverb effect to follow the level of a track’s main fader so that the reverb level follows the overall level. As a result, Bus Sends are set to have post fader routing by default.

Input

For more information on using the options of the Input menu, *see Chapter 168, "Setting Up Tracks, Busses, and Patching."*

The Input dropdown menu allows you to initiate patching any available sources using the Patch Input/Output window.

Path Settings

Choose Input at the top of the Mixer channel strip to access the Path Settings control window. These controls allow you to modify various aspects of the Mixer channel strip that may need adjustment prior to, or post, recording to control the mic/line inputs on Fairlight audio interface hardware, and more.

Path Settings window

Mic/Inst

Controls will only appear on this panel if you have connected channels 1 or 2 of a Fairlight SX36 audio interface to your system. If connected, you can remotely control all of the options (including level) for the mic/instrument inputs of the SX36 if they are assigned to the channel. If there is no connection to an SX36, the area is empty.

Record Level

- **Record:** Linked and identical to the Record Enable button on the channel strip; here for convenience. If you hit one, it will enable the other.
- **Thru:** Allows the input signal to pass into the Mixer without enabling a record path. This is ideal when you want a source signal to always be available and just want to monitor it.
- **Record Level:** Allows you to apply a digital gain adjustment to the record path to disk, post the output of your audio interface's analog-to-digital converter.

  Normally, this control should be left at 0.0 (no change, unity gain), as it affects the level you are recording to disk. It is best practice to use the level controls on your audio interface to control the input level into DaVinci Resolve in order to maximize audio fidelity. However, there might be a time where you need a bit more level, or may not have access to an audio interface's controls, and in those cases you can adjust the input.

Trim

- **Polarity:** Inverts the polarity of the signal coming into the channel strip (sometimes referred to as "flipping the phase"). For example, you may have an input signal like an explosion where the transient attack of the signal produces with a massively positive-going waveform (where the waveform mostly appears above the zero line). If you invert the polarity, the signal will now be mainly negative-going and the waveform will be concentrated beneath the zero line. Inverting polarity is sometimes used to more closely align signals from multiple microphones and can be used creatively to affect frequency response of such a signal.
- **Trim Level:** Allows you to trim the level of the signal coming off of disk, post the Track FX (which process directly off of disk) and pre all other effects. Trim Level appears post the recorded signal to disk and doesn't affect the recording level. Trim is a playback adjustment and allows you to adjust the level of the signal coming into your mix to optimize the level feeding effects and the busses, or to slightly trim an otherwise perfect element in the mix up or down in level.

Direct Output

Each audio channel strip can enable a direct output that can be used to feed any other input destination. You can patch this source using the Track Direct choice in the Patch Input/Output dialog via the Source dropdown.

For more information *see Chapter 168, "Setting Up Tracks, Busses, and Patching."*

- **On/Off:** Enables/disables the direct output.
- **Pre:** Sets the direct output tap-off point to be pre (before) the channel fader. On by default.
- **Level Control:** Sets the level from full off (minus infinity) to +10 dB. Default is 0.0 (unity gain).

Insert

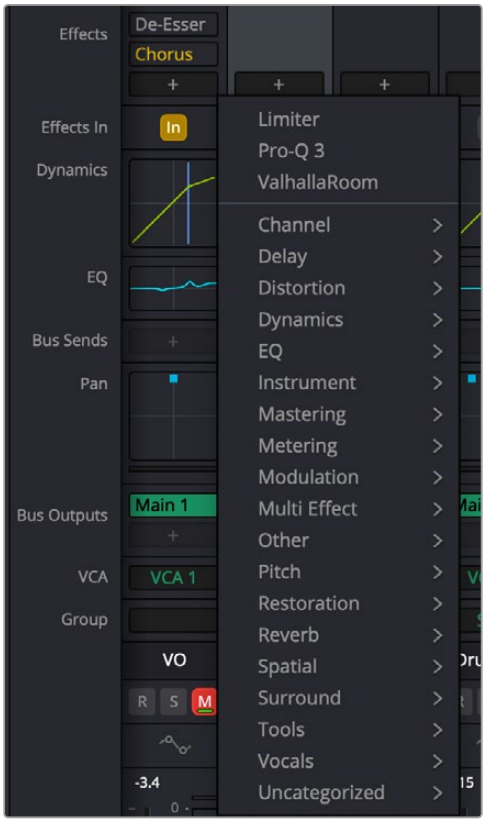
Linked and identical to the Effects In button on the channel strip; here for convenience. If you hit one, it will enable the other. Switches all Fairlight FX, AU, or VST effects on a channel in or out of the signal path with a single switched control.

Effects

Fairlight FX, VST, or Audio Unit effects can be applied on the Mixer's channel strips. Effects are applied on the entire track, not just on one or more clips in the Timeline for that track.

Clicking the plus ("+") button opens a dropdown menu, allowing you to apply any Fairlight FX, VST, or AU effects installed on your machine to that track. The menu is organized by processing type. Within each type, there is a hierarchical choice for Fairlight FX, AU, and VST (if you're on a Mac) or Fairlight FX and VST (if you're on Windows).

NOTE: Depending on what you have installed on your machine, the collection of audio effects available for the Mixer channel strip inserts is often close to (or identical to) those that you can access for clip-based audio processing found in the Effects panel on the left side of Cut, Edit, and Fairlight pages.



Clicking on the plus sigμn shows the Effects dropdown list for assignment

TIP: You can store favorite effects for quick access at the top of the list by marking them as favorites in the Effects panel. Mark a favorite by clicking on the star next to the name.

Hovering the mouse over any listed effect reveals controls for enabling/disabling, replacing or deleting the effect, or opening an effect's custom controls (the user interface for that effect).

Hovering the mouse pointer over an effect insert reveals controls for that effect.

Changing the Order of Effects on a Channel

The order of effects on any Mixer channel strip can be changed by clicking on the Effects Order button. A dropdown menu appears allowing you to change the order between various routing combinations of all insert effects (Fairlight FX, or AU, or VST plugins) and the built-in Dynamics and EQ modules. The default routing is Effects ("FX"), Dynamics, EQ.

Effects Order dropdown menu

Different effects orders can produce very different creative results. For example, it is usually best practice to apply noise reduction first in a signal chain, so you're not affecting the volume or quality of the noise floor you're trying to remove, so the plugin can do its job most effectively. Or you may wish to apply dynamics processing prior to EQ, as changing the spectral content of your source may affect the response of the compressor.

Moving Inserts by Dragging

You can move inserts from one location to another simply by clicking and dragging to a new location. Using this technique, you can move an effect from one channel to another, or swap or move the location of an effect on a channel to another insert position on that channel (displacing the plugin already present). Note that, at this time, you can't use this technique to copy tracks to busses or vice versa.

Copying and Pasting Effects

You can copy entire effect chains with their specific effect parameters intact, track by track. Let's say that you've created a plugin chain on a dialogue track that has Noise Reduction, a De-Hummer, and a Dynamics plugin that you have tweaked to the exact settings needed for those dialogue recordings to sound great.

You also have another track that has similar recordings that could benefit from the exact same chain of plugins and those particular settings. Rather than install each plugin to the track and redo the settings, you can simply right-click the track header (A1 for example) and click Copy. Then go to the track header of the new track you want effected, right-click, and click Paste. You will now have the identical plugin chain copied over to the new track, all with each of the settings exactly as you had created on the source plugin dialogue track

Copying and Pasting Effect Settings

If you have a setting for one effect that you spent a lot of time getting right and see that it could also work just as well on another track's effect, you can copy and paste just those settings.

For example, you have a Reverb on a dialogue track that you have tweaked to perfection. You see that those exact settings will work well for another dialogue track that is on your timeline. Rather than try to recreate those settings, you can duplicate them.

- Hold down the option key and drag the Reverb plugin you want to copy to a new location. This creates a copy at the new location and leaves the original intact.
- Alternatively, you can use Copy and Paste in the plugin three dot Options menu. To apply those settings to the other track, just click Copy from the Options menu of the source Reverb effect, then open the Reverb plugin window of the destination Reverb effect, and click the Options menu to paste. Now all of the parameters are the identical between the two plugins.

For more information on using audio effects, *see Chapter 177, "Audio Effects."*

TIP: You can create and load presets for entire channel strips and use them in any project or timeline using the Fairlight > Presets Library.

Effects In

The Effects In button allows you to bypass all Fairlight FX, AU, or VST effects plugins for the channel with a single control. When it is lit (orange), all effects are enabled; when it is unlit, all effects are bypassed.

NOTE: Track FX (Voice Isolation with Resolve Studio and Dialogue Leveler) and the built-in Dynamics and EQ processors are not affected by Effects In.

Dynamics

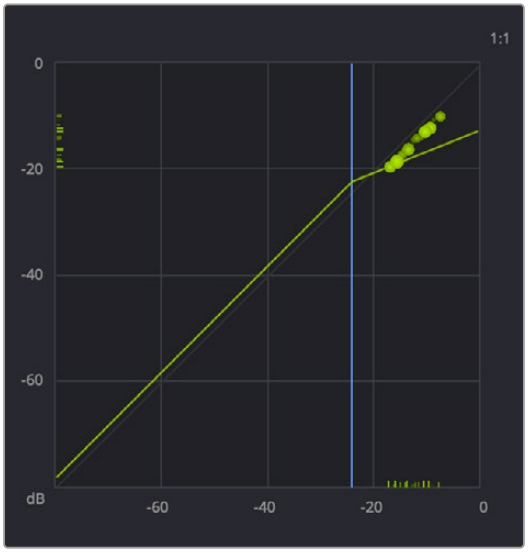
Each Mixer channel strip has a built-in Dynamics processor, with a mini Dynamics Indicator graph that appears on the channel strip and acts as the access button. Double-clicking the Dynamics Indicator brings up the Dynamics processor window, with three modules: an Expander/Gate, a Compressor, and a Limiter. Each can be used separately or in concert to manage the dynamics of the audio on the target track.

The Dynamics control window

The Dynamics Graph

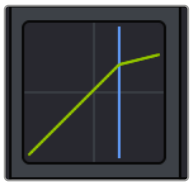
When you enable any combination of the Dynamics window modules you may need for a track, the Dynamics graph updates with curves that show you how the signal is being affected by the Expander/Gate, Compressor, and/or Limiter settings that are being applied. The Dynamics graph also provides a real time animated display that meters the true response of the input/output signals compared to the graphic that shows the basic response curve.

- The X axis (horizontal scale) represents the input signal level.
- The Y axis (vertical scale) represents the output level.
- The blue line represents the threshold.
- The light green line represents the dynamics curve (dependent on the process type and setting; this will change).
- The light green balls that animate in the upper area of the graph follow how the Dynamics control settings affect the signal as it moves above or below the threshold. The balls are affected by the attack and release settings, allowing you to visualize the way the compressor is affecting the input signal.
- The smaller lines that appear on the on the input and outline X-Y lines allow you to see exactly where the input/output levels are.



The Dynamics graph shows the response curve and how the signal is being affected by the current settings in real time.

The Dynamics Indicator on the channel strip displays the same curve, so you can see at a glance what is happening on that channel (but without the real time display). This indicator cannot be adjusted; you must open the Dynamics window to make modifications.



The channel strip Dynamics Indicator

Master Dynamics Controls

The Dynamics window contains the following overall controls at the top of the window:

- **Enable button:** Turns the overall dynamics effect off and on, without resetting the controls.

> **NOTE:** You can also turn dynamics on/off by single clicking on the Dynamics button (the mini graph) in the channel strip.

- **Reset button:** The circular reset icon on upper right next to the three dot Options menu resets all controls of the Dynamics window to their defaults.
- **Preset Menu:** Dynamics presets appear here. You can create, change, and save presets, and use the default presets as good starting points for your track's specific needs.
- **Make Up Gain control:** A post-dynamics level control that lets you boost the signal to compensate for dynamics settings that may have lowered the overall level.

Expander/Gate

The first of three sets of dynamics modules, the Expander/Gate controls can be switched between expansion and gating. Expansion emphasizes differences in volume by lowering the level of soft parts of the signal relative to the level of louder parts and can be used to minimize noise while increasing the dynamic range of a signal. Gating reduces the level or even silences parts of a signal that fall below the set threshold level in order to reduce or eliminate noise in quiet parts of a recording.

- **Expander:** This button enables the Expander.

  Threshold: Sets the signal level below which expansion occurs. Defaults to –35 dB. The range is from –50 to 0 dB.

  Range: Amount of decrease in signal level in dB, affected by both threshold and ratio. As ratio increases, range can have more of an effect. At lower ratios, as threshold increases, the effect of range increases.

  Ratio: Sets the attenuation ratio (input to output) applied to signals which fall below the threshold level. It controls the rate at which signals will drop, while Range controls how much the signal will drop. Defaults to 1:1.1. The range is 1:1.1 to 1:3.0.

  Attack: Adjusts how quickly the expansion occurs when a signal exceeds the threshold. Defaults to 1.4 ms (milliseconds). The range is 0 to 100 ms.

  Hold: Controls how long the Expander is kept open after the input has fallen below the threshold, in ms. Defaults to 0 ms. The range is from 0 to 4000 ms (4 seconds).

  Release: Adjusts how quickly or gradually the Expander attenuates when the input signal goes back below the threshold. Defaults to 93 ms. The range is 50 to 4000 ms (4 seconds).

- **Gate:** This button enables the Gate.

  Threshold: Sets the signal level below which gain reduction occurs. The range is from –50 to 0 dB.

  Hold: Controls how long time the Gate is kept open after the input has fallen below the threshold, in ms. Defaults to 0 ms. The range is from 0 to 4000 ms (4 seconds).

  Range: Sets the maximum amount of gain reduction that will be applied when the signal falls below the gate threshold. Once the signal has fallen below the level determined by the gate threshold minus the gate range, no gain reduction is applied. The default is 18 dB. The range is from 0 to 60.2 dB.

  Ratio: Unused for gate.

  Attack: Adjusts how quickly the gating occurs when a signal exceeds the threshold. Defaults to 1.4 ms. The range is 0 to 100 ms.

  Hold: Keeps dynamics from being triggered again until a certain amount of time has passed, in ms (milliseconds). Defaults to 0 ms. The range is from 0 to 4000 ms (4 seconds).

  Release: Adjusts how quickly or gradually the sidechain detector stops attenuating when the input signal goes back below the threshold. Defaults to 93 ms. The range is 50 to 4000 ms (4 seconds).

Compressor

The second set of dynamics parameters let you apply compression, which detects the envelope of an audio signal in order to automatically change its level. A compressor is used to compress a signal's dynamic range by reducing differences in level between the loudest and quietest parts of the input signal.

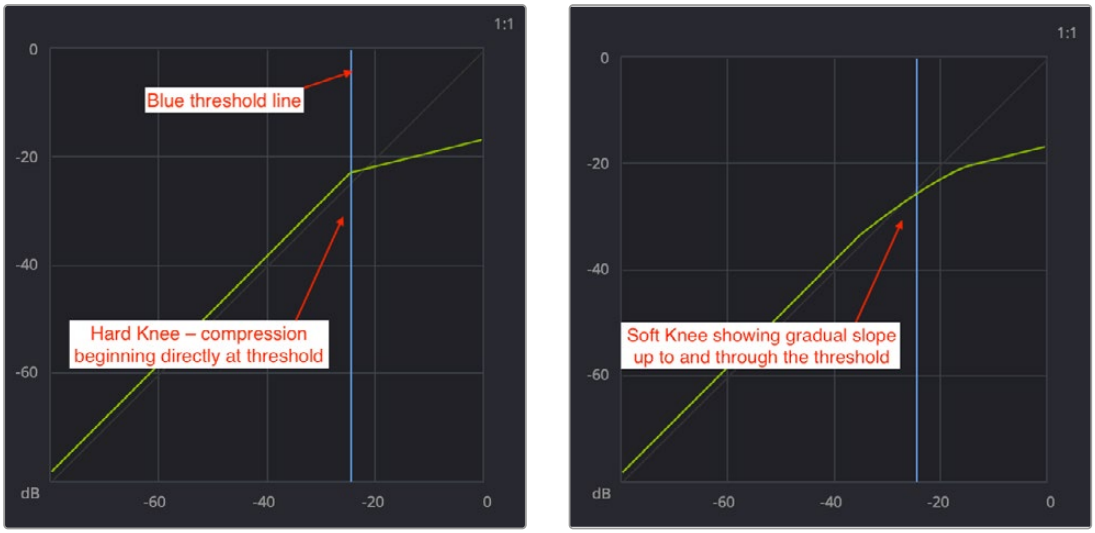
Compression can be used to raise the signal's overall level to be boosted without clipping, increasing perceived loudness. Compression is often used to allow voices to have more presence within a mix, and to smooth out changes in the levels of tracks with too much dynamic range for the task at hand.

However, “overcompressing” can remove natural dynamics of a sound, or remove too many of the natural transients (energy bursts or “attacks”) that give the original sound its character. But more extreme compression can also be used creatively to change a sound’s character to give it more perceived attack, change its release characteristic, or change the balance and blend of the environment a sound is recorded in (for example, compressing a source signal with a higher ratio and fast release to raise up the presence of a room sound that the source is recorded in).

- **Compressor:** Enables the Compressor.
- **Threshold:** Sets the signal level above which compression is applied. The default is –15 dB. The range is –50 to 0 dB.
- **Ratio:** Adjusts the compression ratio. This sets the gain reduction ratio (input to output) applied to signals which rise above the threshold level. The default is 2.0:1. The range is 1.0:1 to 10:1. Commonly used ratios for dialogue processing are 2.5:1 to 3:1. With a 3:1 ratio, for every 3 dB of increase in signal above the threshold, 1 dB is output.
- **Knee:** Affects behavior with signals that are very near the threshold. The knee can smooth out the transition between where you don’t hear any compression and when the “hard compression” (the set ratio) starts.

  The Knee: Control allows a smoothing of the slope of the threshold point. You can see Knee’s effect on the graph when using a ratio like 4:1 and adjusting Knee; the graph will show the line where compression “kicks in” being rounded off by higher values of the Knee control.

  Normally, compression begins directly above the threshold. This is known as a “hard knee.” For a smoother and less audible handling of compression, you can set a softer knee, so the compression turns on gradually as signals approach the threshold and rise above.



Hard and Soft Knee graphs

Mix: Adjusts the mix between the compressed (0) and non-compressed input signal (100), allowing you to balance the compressed signal against the original, unaffected sound. For example, if you’re creating a large explosion impact sound effect, it might sometimes be useful to mix in just a bit of the original, uncompressed signal with a more compressed version to preserve more of the original character along with compressed version. The default is 0 (all compression, no original signal).

Attack: Adjusts how quickly the compression will occur when a signal exceeds the threshold. The default is 1.4 ms. The range is 0 to 100 ms.

Hold: After the attack phase has been completed, the Hold parameter controls how long this initial attenuation is maintained, before entering the release phase. Defaults to 0 ms. The range is from 0 to 4000 ms.

Release: Adjusts how quickly or gradually the sidechain detector stops applying compression when a signal falls back below the threshold. The default is 93 ms. The range is 50 to 4000 ms (4 seconds).

Sidechain: This redesigned section lets you set up sidechain compression or “ducking” using the parameters and controls listed below, instead of using a Send from a track or bus to feed the sidechain input:

Sidechain module

On: When clicked, this button turns red indicating that the Sidechain module is active.

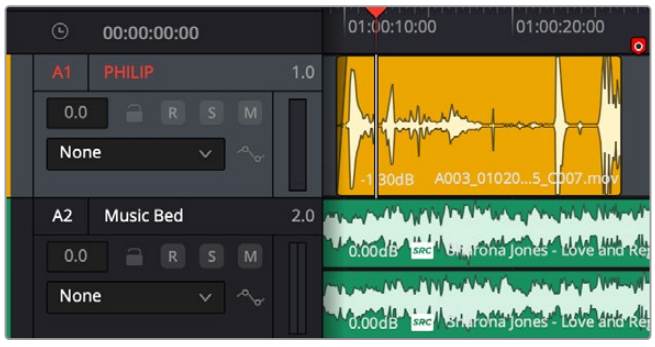
Listen: Clicking this button lets you hear the incoming signal on its own, which is helpful if you need to confirm that the correct audio signal is being sent to the Sidechain module.

Source: This button selects the track or bus the incoming audio is coming from.

Sidechaining and “Ducking” with Dynamics

The Dynamics module allows you to set up “sidechain” compression, which lets you temporarily lower the level of a target track or bus using the audible signal from a source track or bus.

For example, you may have a dialogue on a track or bus (the source) and another with music (the target), and you want the dialogue to be heard more prominently. This can be done by following the steps below:



Choosing the track header in the Fairlight timeline to add dynamics

1. Open the Dynamics plugin on the music track or bus, and switch on the Compressor.
2. Click the Source dropdown and select the dialogue track or bus.

TIP: Using a bus as the ducking source lets you use multiple sources to trigger changes in your target track.

3 Click the On button, which turns red, indicating that the Sidechain section is active.

4 While playing a section of your mix, set the amount of gain reduction by lowering the Threshold and raising the Ratio until the target audio is attenuated to a level that makes the dialogue more audible.

5 If needed, adjust the Hold parameter to ensure the gain reduction doesn't fluctuate too wildly.

6 You may also need to adjust the Release parameter to stop the gain reduction from ending too abruptly.

Clicking the Listen button lets you hear the incoming signal if you need to confirm that the correct input signal is coming into the Limiter. This button turns yellow when active.

Limiter

The third set of dynamics parameters let you apply limiting, which imposes a targeted maximum level allowed for a signal. Limiting is similar to compression but essentially has a very high ratio.

- **Limiter:** Enables the Limiter.

  Threshold: Sets the threshold above which limiting will occur. As the Limiter is designed to hard limit the output, this also essentially sets maximum allowable output level. The default is –21 dB. The range is from –50 to 0 dB. It's best to set the amount of limiting by listening, and looking at the amount of gain reduction in the meter. Too much limiting can "squash the life out of the sound" as all of the internal dynamics of a mix can be lost. Used properly, you can smooth out the final mix and achieve higher average level. You can also watch the yellow animated balls in the display to see how the real time limiting response is affected by the controls.

  Attack: Adjusts the attack rate time constant of the sidechain detector. The default is 0.71 ms. The range is 0 to 100 ms.

  Hold: Once the input level falls below the threshold, Hold keeps limiting active until the hold time has elapsed, when release time will start. Default is 0 ms. The range is from 0 to 4000 ms.

  Release: Adjusts how quickly the sidechain detector stops applying limiting when the signal falls below the threshold. The default is 90 ms. The range is 50 to 4000 ms.

NOTE: When limiting is applied to the final output of your channel (or to an entire mix), you often will need to use the Makeup Gain slider to maximize the output level (if a master) or to match the original level of an individual track (unity). You can audition the difference in level by bypassing the Dynamics module overall, or the Limiter only.

EQ

Each Mixer channel strip has a 6-band equalizer EQ, with a mini-EQ graph that displays the current EQ curve, bypasses the plugin, and opens it when double-clicked.

This plugin offers a choice of high and low shelving, parametric or notch response curves, and high and low pass filters with selectable slopes up to 24dB/octave, with controls for boosting and attenuating different frequency ranges.

Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band), with the available controls for each band of EQ changing depending on the filter type.

You also have a choice of four response curves, from the Native Fairlight response curve to emulations of classic EQs.

The channel strip EQ window

The channel strip's EQ Indicator.
(Left) EQ is adjusted, and (Right) EQ is flat (no EQ).

Master EQ Controls

The Equalizer window has the following overall controls:

- **Enable button:** Turns the plugin on and off.
- **Reset button:** The circular Reset icon on the upper right of the EQ resets all parameters to their default settings and values.
- **Equalizer Type:** This dropdown offers the Native Fairlight response curve and three emulations of classic mixing console EQs.

  Earth: Native Fairlight response (Default)

  Air: SSL 4K

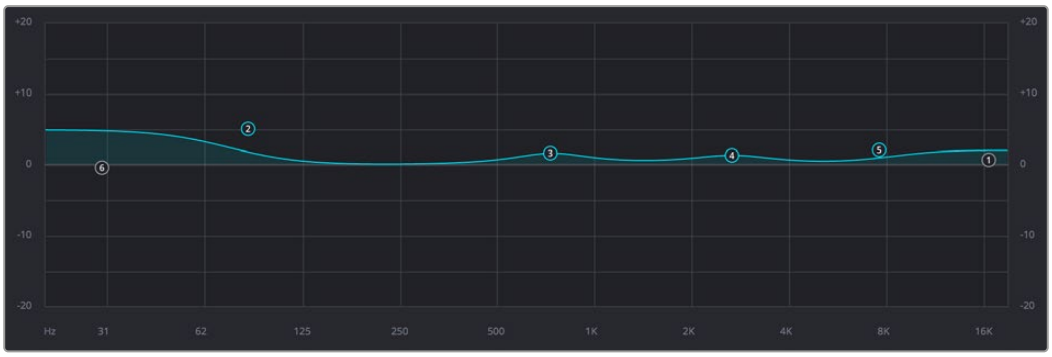
  Ice: Neve V

  Fire: Focusrite

- **Preset Menu:** Your EQ settings can be saved as presets by clicking the Plus button to the left of the Preset menu.
- **Gain fader:** This post-EQ fader lets you boost or attenuate the processed signal to compensate for your EQ adjustments.

The EQ Graph

The EQ graph provides a visual representation of the current EQ settings, with numbered “handles” for each active EQ band, which can be dragged in any direction to change the corresponding frequency and level. You can also use your mouse wheel to adjust the Q (bandwidth) of each band.



The EQ graph

Dragging the numbered handles on this graph in turn modifies the parameters of the corresponding band, and conversely, changing each band’s parameters will also alter the EQ graph, which serves the additional purpose of providing a graphical representation of the equalization curve being applied to that track. If you have a mouse wheel, it can be used to control Q.

Bands 1 and 6

The outer two sets of band parameters are for processing the lowest or highest frequencies of an audio signal.

Band 1 controls active

Band 6 controls active

- **Band filter type:** Clicking the Band 1 or Band 6 buttons activates or deactivates their respective controls.
- **Band filter type:** Bands 1 and 6 are switched off by default, but when active, they each allow access to filtering options below:

  Band 1: Low Shelf, Low Peak, High Shelf, and High Pass.

  Band 6: Low Pass, Low Shelf, High Peak, and High Shelf.
- **Frequency:** Adjusts the center frequency of the EQ band.
- **Filter Slope:** The high and low pass filters offer selectable slopes starting at 6dB/octave up to 24dB/octave.
- **Gain:** When bands 1 and 6 are set to a peaking or shelving response curve, this parameter cuts or boosts the selected frequency with a range of ±20 dB.

Bands 2–5

The middle four sets of band controls let you make a wide variety of equalization adjustments. They're on by default to make it easy to begin making adjustments.

The Band 3 controls

- **Band enable button:** Clicking these Band buttons activates or deactivates their respective controls.
- **Band filter type:** Bands 2 to 5 offer the following filtering options: Low Shelf, Peaking, Notch, and High Shelf.
- **Frequency:** Adjusts the center frequency of the EQ adjustment.
- **L, ML, MH, H Buttons:** These buttons restrict the center frequency of a band to one of the following frequency ranges: Low, Medium Low, Medium High, or High.
- **Gain:** This control is available when a band is set to a peaking or shelving response curve and adjusts the level of the center frequency within a range of ±20 dB.
- **Q Factor:** This parameter is available when a band is set to a peaking response or when the Equalizer type is set to Fire and adjusts the bandwidth of an EQ band, with a range of .3 to 10.3.

  Smaller Q factors widen the bandwidth, while higher values make it narrower, determining how much neighboring frequencies are also affected as the center frequency is adjusted.

Bus Sends

Bus Sends let you route a channel strip's source signals to a bus destination, with control over level, pan, mute, and pre/post fader routing. You can create bus sends on channels that go to any bus destination you've created.

Some common mixing tasks that sends can be useful for:

- **Submixing:** For example, to render separate mixed outputs that are different formats, such as stereo, 5.1 surround, or Dolby Atmos, all at the same time.
- **Feeding signals to a shared effect:** For example, route to a reverb plugin, where post fader sends on various mixer channels feed a reverb placed on a bus channel strip by varying amounts.
- **Headphone cue mixes:** Create separate pre-fader mixes for the talent so you don't disturb what you're listening to on your main monitor speakers.

Creating Sends

To create a Bus Send and access its controls:

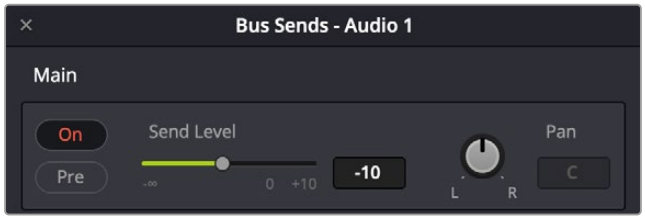
- Click on the assign button with the plus sign (+) in the Bus Sends area of the Mixer.
- A dropdown menu appears with a list of busses; select one to assign.
- Your send is now created.

You can hover over the rectangular name button and access a disable/bypass button, an access icon to show the Bus Send window for the channel, and an “x” to delete the send. A tooltip appears showing the send bus name.

Hovering over the rectangular name button will show send controls.

Accessing the Bus Sends Window

You can access the Bus Sends window to control a channel’s sends by clicking in the center of the name button.



Bus Send window controls

Each Bus Send you create exposes the following controls in the Bus Send window:

- **On:** Turns the send on or off.
- **Pre:** Switches the send to use pre- or post-fader routing. Enabling this button allows that track to send levels to the destination bus before level adjustments on that track are applied.
- **Send Level:** Adjusts the amount of signal sent from the selected feed to the send bus. The range is OFF to +10dB.
- **Pan:** Provides panning across Bus Send destinations.

Uses for Pre-fader Routing

One common use of pre-fader sends is for cue mixes to ADR or voice over talent, where the artist wants to hear a completely different mix than the control room mix. Using pre-fader sends and setting up a complete mix to a bus that feeds the headphone system allows a mix that is completely independent.

Pre-fader sends can also be used for special creative effects that might involve a dialogue channel being sent to a reverb plugin via a send. If the send is routed pre-fader, when the main channel fader is lowered to close to zero, the dialogue is still being fed to the reverb, so the dialogue will sound extremely reverberant (almost all of the signal is “wet”). Gradually raising the channel fader will make it sound like the voice is moving closer to the listener, changing the reverb balance and sounding more present.

Bus send levels are shown in the rectangles for each send and have the color codes assigned to the destination busses.

Bus Send levels shown on the Mixer channel strip

Legacy Bus Sends – “Auxiliaries”

Prior to DaVinci Resolve 17, the Bus Send panel was called Auxiliaries. Any projects created prior to DaVinci Resolve 17 will use the legacy Fixed Busing. The only difference between the two is the use of “Aux” to refer to sends in the windows and titles.

Pan

The Fairlight Mixer provides 2D and 3D pan controls that support various audio formats ranging from mono and stereo to conventional 5.1 and 7.1 surround, as well as advanced immersive formats such as Dolby Atmos, Ambisonics, Auro 3D, and NHK 22.2.

Channel Strip Pan Controls

The Pan section of each Channel Strip includes a Panning Indicator offering visualization and panning control of left, right, front, and back.

Although you can open the Panner to access additional parameters by double-clicking the Panning indicator, you can also do the following in the channel strip Pan section while the Panner is closed:

- Click and drag within the Pan Indicator to adjust the basic panning position.
- Single click to bypass panning.
- Command-drag to adjust the width on multichannel tracks.
- View the Boom level for surround channels, which is displayed as a horizontal blue line at the bottom of the Panning Indicator.

Channel strip
Pan Indicator for
a stereo track

2D Panner Controls

Default View

The Pan window's control set varies based on the mapping of the source audio. Panning adjustments can be made by dragging the icons in the Panner Viewer or using the controls on the left side of the window.

The Panner control window – Default 2D view

The default 2D version of the Audio Pan window includes the following controls:

- **Pan Enable:** Switches the Panner on and off.
- **Spherical:** This button changes the Panner interface from the default 2D view to the 2D Spherical top-down view.
- **3D:** Clicking this button switches the interface to the 3D Cartesian view, offering controls for working with immersive audio formats such as Dolby Atmos, Ambisonics, Auro 3D, and NHK 22.2, as described in the 3D Pan Controls section below.
- Clicking the Spherical and 3D buttons switches the interface to the 3D Spherical view.
- **Left/Right:** Changes the balance of the signal between the left and right speakers, depending on the speaker configuration you're mixing for.
- **Front/Back:** Lets you adjust the balance of the signal between the front and rear speakers based on the surround format you're mixing in.
- **Rotate:** This controller rotates the sound source (or sources) around the listening position in the center of the sound field.

- **Spread:** In the case of multichannel audio, this adjusts the spread or distance between the sound sources. This is measured on a numeric scale of 1-99, where 1 is labeled PNT (“Point”) and 99 is labeled FULL.
- **Divergence:** Determines the amount of signal bleed or spillover of a signal from one speaker into adjacent loudspeakers, allowing the sound to occupy more of the sound field, with less focus toward a single speaker position. The amount of signal bleed is represented by green horizontal lines emanating from either side of each speaker position that increases in length as you raise the parameter value.

  2D: Clicking this button changes the appearance of the divergence indicators to circles.
- **Boom:** This adjusts the send level to the LFE part of the mix (the Low-Frequency Extension subwoofer system).

  On: Enables the Boom output.

  Pre: Routes the LFE signal pre-fader.

Boom parameter

TIP: To constrain left/right position as you adjust panning, hold down the Shift key. You can reset any rotary control to its default value by double-clicking it.

Spherical View

The Panner control window – Spherical view

Clicking the Spherical button at the top of the 2D Panner changes the interface to Spherical view, which has the controls listed below including two parameters for Ambisonic panning:

- **Azimuth:** This control lets you rotate the sound source around the circumference of the sphere.
- **Distance:** This control adjusts the distance between the signal source and the listening position at the center of the sphere.
- **Rotate:** This controller rotates the sound source (or sources) around the listening position in the center of the sound field.
- **Spread:** In the case of multichannel audio, this adjusts the spread or distance between the sound sources. This is measured on a numeric scale of 1-99, where 1 is labeled PNT (“Point”) and 99 is labeled FULL.
- **Size:** This parameter is not active at the time of writing.
- **2D:** This parameter is not active at the time of writing.
- **Boom:** This adjusts the send level to the LFE part of the mix (the Low-Frequency Extension subwoofer system).
- **On:** Enables the Boom output.
- **Pre:** Routes the LFE signal pre-fader.

3D Panner Controls

DaVinci Resolve includes 3D Cartesian and Spherical versions of this Panner, which lets you do spatial audio positioning when working in advanced surround formats such as Dolby Atmos, Ambisonics, Auro 3D, and NHK 22.2.

Cartesian View

The 3D Panner control window - Default Cartesian view

Clicking the 3D button changes the Panner interface to the default Cartesian view, which includes a few more controls than the 2D Pan window:

- **Pan enable:** Toggles the Panner on and off.
- **Snap:** This button toggles Speaker Snap mode on and off for a given object. During playback, Speaker Snap mode moves an audio object to the active speaker nearest its established location, to prevent issues like phantom panning.

- **Panner viewer:** A large 3D representation of the virtual room, with a blue sphere representing the position of the track's audio.

  Perspective Buttons: These buttons let you view the room from different preset angles. You can freely rotate it by holding down Command-Option-Shift (Ctrl + Alt + Shift in Windows) while dragging it. If you want to return to a default view, click one of the perspective buttons.
- **Front panner:** A 2D panning control that lets you make adjustments along the horizontal Left/Right axis and the vertical Down/Up axis.
- **Side panner:** A 2D panning control that lets you make adjustments along the horizontal Front/Back axis and the vertical Down/Up axis.
- **Top panner:** A 2D panning control that represents the horizontal left/right axis the vertical front/back axis, letting you make these specific spatial adjustments.
- **Left/Right:** Changes the balance of the signal between the left and right speakers, depending on the speaker configuration you're mixing for.
- **Front/Back:** Lets you adjust the balance of the signal between the front and rear speakers based on the surround format you are mixing in.
- **Down/Up:** This lets you change the position of a sound source along the vertical axis.
- **Height Mode Presets:** Located to the right of the Down/Up control, these three height presets lock the interaction of the Front/Back and Down/Up parameters together, providing fixed panning paths that raise the height of a sound source to its maximum (100U), while moving it from one end of the sound field to the other.

  Freeform: This is the default setting for this section, which lets you adjust the Down/Up and Front/Back controls independently.

  Flyover: Moves the sound source upwards in a sharp arc to 100U, and then from one end of the sound field to the other while maintaining maximum height.

  Triangular: This preset moves the source diagonally up to 100U and immediately back down again as it travels from one end of the sound field to the other.

  Arc: Moves the sound source upwards in an arc to 100U and immediately back down in the same manner as it travels from one end of the sound field to the other.
- **Rotate:** This controller rotates the sound source or mix around the listening position in the center of the sound field.
- **Tilt:** This knob tilts a sound source or mix up to ninety degrees to either side so that it vertically rotates or "swings" around the listening position in the center of the sound field.
- **Spread:** In the case of multichannel audio, this adjusts the spread or distance between the sound sources. This is measured on a numeric scale of 1-99, where 1 is labeled PNT ("Point") and 99 is labeled FULL.
- **Divergence:** Determines the amount of signal bleed or spillover of a signal from one speaker into adjacent loudspeakers, allowing the sound to occupy more of the sound field, with less focus toward a single speaker position. The amount of signal bleed is represented by green horizontal lines emanating from either side of each speaker position that increases in length as you raise the parameter value.

  2D: Clicking this button changes the appearance of the divergence indicators to circles.
- **Boom:** This adjusts the send level to the LFE part of the mix (the Low-Frequency Extension subwoofer system).

  On: Enables the Boom output.

  Pre: Routes the LFE signal pre-fader.

  Only: Allows the panner to output an LFE signal only from the channel. The Boom level line in the channel strip Pan Indicator is gray when this button is active.

Cartesian View - Dolby Atmos

The 3D Panner control window - Cartesian view – Dolby Atmos

When working in a Dolby Atmos workflow, the 3D Cartesian view of the Panner includes all the features mentioned above for the default Cartesian view, with the addition of the following controls located at the top of the interface:

NOTE: These controls are not available on Dolby Atmos busses.

- **Elevation Button:** This button hides and reveals the four top speakers in the Viewer.
- **Zone:** In addition to the option to view all speakers this dropdown menu offers five others that let you include or exclude certain speakers from this object's mix:

  No Back: Hides the rear surround speakers.

  No Sides: Hides the side surround speakers.

  Center Back: Shows only the Center and Rear speakers.

  Screen Only: Shows only the Center and Left and Right Front speakers.

  Surr (Surround) Only: Show only the Surround speakers.

Spherical View

The 3D Spherical Panner control window

The 3D Spherical Panner lets you position your source anywhere in the sound field, including above and below the listener. Spherical panning is based on Azimuth, Elevation, and Distance.

This view of the 3D panner offers the following controls:

- **Azimuth:** This control rotates the sound source around the circumference of the sphere.
- **Elevation:** This raises and lowers the sound source towards the top and bottom of the sphere, which allows you to place it above or below the listener if you want.
- **Distance:** This control adjusts the distance between the signal source and the listening position at the center of the sphere.
- **Rotate:** Rotates the sound source (or sources) around the listening position in the center of the sound field.
- **Spread:** This control adjusts the spread or distance between the sound sources. This is measured on a numeric scale of 1-99, where 1 is labeled PNT (“Point”) and 99 is labeled FULL.
- **Size:** This parameter is not active at the time of writing.
- **Room:** This parameter is not active at the time of writing.
- **Pitch:** This knob tilts the sound source or mix, forward or backward while rotating or “swinging” it up to ninety degrees around the center listening position.
- **Roll:** This knob tilts a sound source or mix, up to ninety degrees to either side so that it vertically rotates or “swings” around the center listening position.
- **Panner viewer:** A large 3D representation of the spherical sound field, with a blue sphere representing the position of the track’s audio.
- **Perspective Buttons:** These buttons let you view the Sphere from different preset angles. You can freely rotate it by holding down Command-Option-Shift (Ctrl + Alt + Shift in Windows) while dragging it. If you want to return to a default view, click one of the perspective buttons.

Bus Assignment Buttons

To route a bus created in the Bus Assignment dialog directly on the Mixer, click the + sign to see a dropdown menu of available busses. To route multiple busses simultaneously, Command-Click (Ctrl+Click) each of your choices in the dropdown menu.

The Bus Outputs panel is where you can route bus signals.

Legacy Mixer Bus Assignment

In the Legacy Mixer the bus assignments have two sets of buttons that let you route audio from one channel strip's output to Sub and Main busses that you've set up for your mix.

The channel strip's Bus Assignment buttons

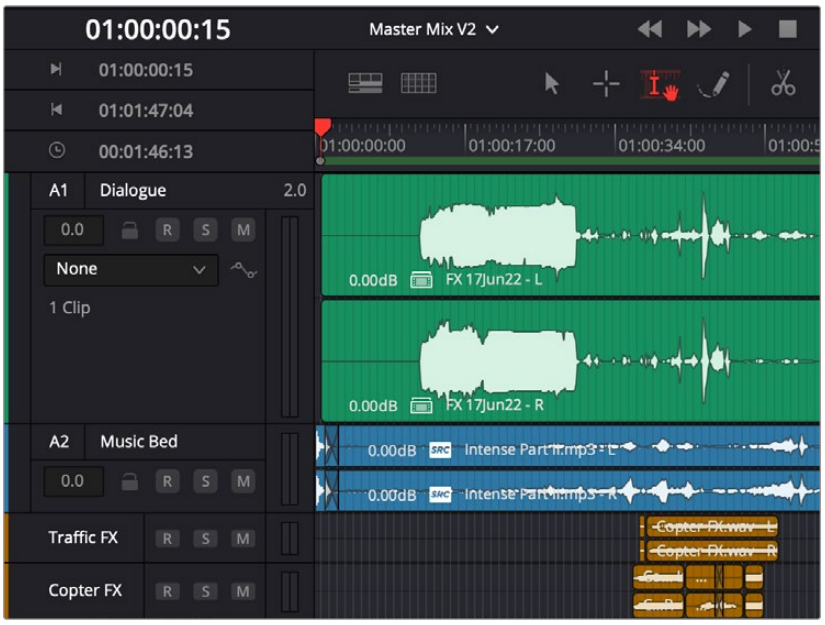
- **Main:** These buttons let you assign a track or sub's channels to one or more of the main busses.
- **Submix:** These buttons let you assign that track's channels to one or more submix busses.

Nested Audio Timelines

Edited timelines can be combined with other timelines by dragging the desired nested timeline onto an empty track in the destination timeline. This is a very powerful and useful feature.

For general information about nested timelines, *see Chapter 43, "Take Selectors, Compound Clips, and Nested Timelines."*

For example, you might have created a master timeline that will contain your master mix, and you'd like to bring the work done on a separate timeline that is focused on dialogue editing. The dialogue timeline could now appear as a single nested timeline, represented as single track in the master mixing timeline.

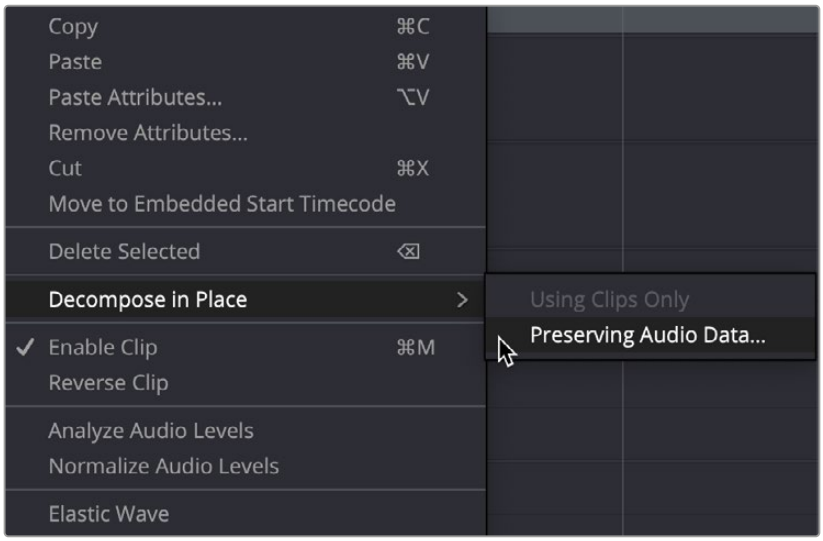


Track A1, Dialogue, is a stereo representation of an edited timeline.

If you want to work with the individual tracks and clips again, you can use a process called decompose to change that single nested timeline track back to the edited sequence. There are a number of options to decompose to the original set of tracks, with several bussing options available.

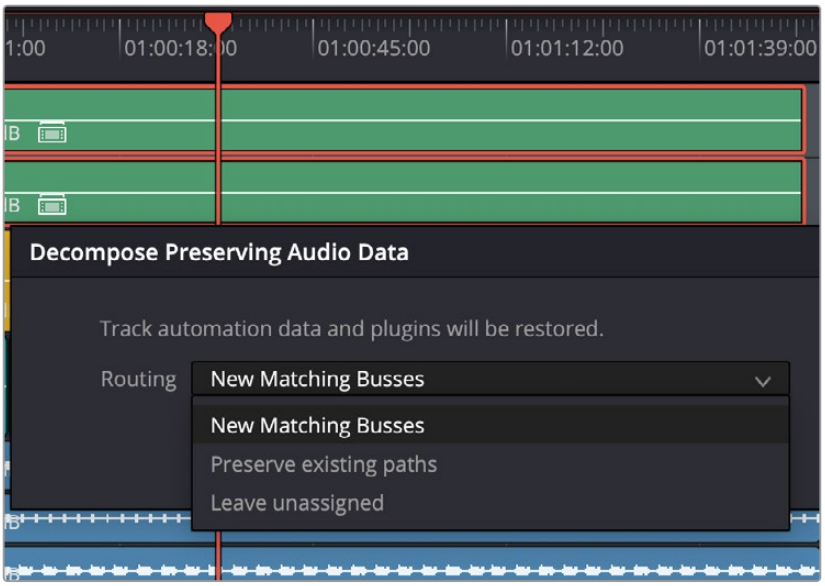
This image shows what was a separate, edited timeline of tracks of dialogue and is now a single track, A1 Dialogue, brought into the destination master mix timeline. By right-clicking the clip, a contextual menu allows you to decompose the track in place, back into its original tracks and clip edits.

There are two decompose options for this. On the Fairlight page, you can Preserve Audio Data, and when on the Edit page, you can Preserve Audio Data as well as decompose by Using Clips Only.



Decompose in Place contextual menu

Once you've chosen to decompose the track into its prior Timeline elements, then the Decompose Preserving Audio Data dialog box appears, making several more options are available.



Options for signal routing when decomposing a clip

There are three options when choosing to decompose a nested timeline in the Fairlight page. All three options preserve mix and plugin automation on the source tracks; they only differ in terms of routing. The choices are:

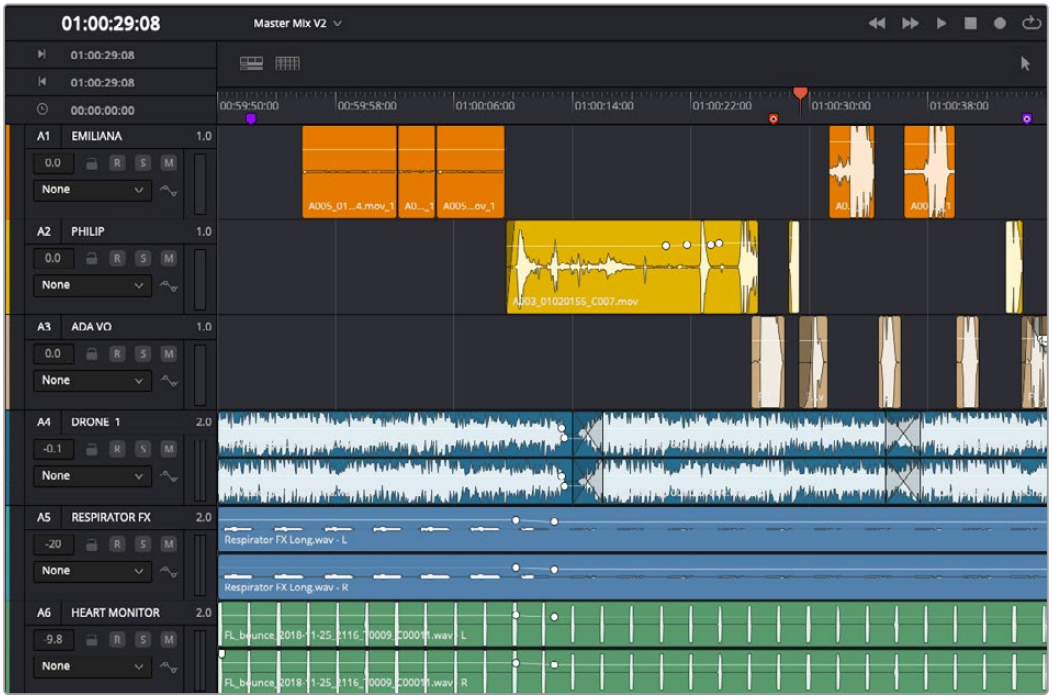
- **New Matching Busses:** All of the busses from the nested source timeline are brought into the current timeline as separate, new busses. These busses will have all of the processing, routings, settings, and automation carried over from the nested source timeline. Any preexisting bus routing in the destination timeline is left unaltered.

  This option is best when you want combine different mix layouts and to preserve all preexisting bus routing in the destination timeline, while adding the bus topology from the nested source timeline to the destination to create a single, larger entity.

- **Preserve Existing Paths:** This option preserves all of the master bus information in the current timeline and routes matching busses from the decomposed nested timeline to preexisting, identical busses in the destination timeline.

  This option is best when the nested source timeline and the destination timeline share the same bus routing structure, as might be the case of a common layout template. In this case, you just want to add the tracks to the destination timeline and route them to the same designations in the master. You still get all of your mix automation and plugins carried across as well.

- **Leave Unassigned:** This option leaves the new tracks unassigned when created, ready to be routed in whatever way you need.



Decomposed version of the nested dialogue timeline showing the original dialogue tracks and edits

Nested audio timelines can be very useful when managing large projects with many tracks and sophisticated routing. Multiple editors can be working on various aspects at one time. For instance, a dialogue editor could be doing the dialogue and ADR in one timeline, an effects editor can be designing and spotting effects in another timeline, a music editor can be cutting and spotting music in another timeline, all separately. Then these interim timelines can be imported later to a master timeline for a final main mix.

This is also useful for picture editors who don't want to have to deal with many tracks of audio when cutting picture. When working in the Edit page, when a track sequence is decomposed, it can also revert back to the original track layout with all of the audio clips ready to be further edited.

VCA Faders

A VCA fader is used to control the level of multiple tracks with a single control. You can assign multiple faders to a dedicated VCA, and a VCA channel strip then appears at the right of the Mixer. VCAs let you simultaneously adjust the underlying level of multiple faders using one VCA master fader and can be helpful in managing the levels of complex collections of audio tracks.

Group Labels in each control strip, above the control strip label

The controls for doing this are found in the VCA and Group label area of each mixer channel strip, which shows which VCA or Track Group each fader has been assigned to.

Making Fader VCA Assignments

You can assign any channel strip to one of 64 VCAs by right-clicking the VCA label area and choosing a VCA from the dropdown that appears. If a fader is already assigned to a VCA, you can choose “No VCA” to remove it.

NOTE: To reduce unneeded clutter, the VCA Assignment dropdown menu will only display 10 VCAs initially; others are added as needed. If the first 10 have all been assigned, the menu display will add VCAs from the available pool, one a a time.

Right-clicking a VCA Label reveals a dropdown menu that lets you assign faders to or remove faders from that VCA.

TIP: You can quickly assign VCAs for a selected group of channel strips, or to all channel strips, by holding down the Option key (Mac) or the Alt key (Windows) for all selected tracks or Command-Option (Mac) or Control-Alt (Windows) for all mixer channel strips prior to performing the operation. These shortcuts can save a lot of time in your workflow.

Using VCA Faders

Once you've assigned multiple faders to a VCA, a dedicated channel strip for that VCA appears at the right side of the Mixer. Making adjustments to the VCA channel strip simultaneously controls all the faders, solo buttons, and mute buttons of all channel strips that are members of that group, as seen below.

Adjusting the VCA 1 fader also adjusts the SYNC, VO, and Drum Hit faders that are assigned to that VCA.

When controlling faders belonging to a VCA, you can still move each individual channel strip fader independently to make relative adjustments.

- Channel strip faders only move together when you adjust the VCA fader.
- While the VCA fader is being moved, each individual fader's relative offset from other faders controlled by the VCA is maintained.

  For example, as seen in the screenshot above, the VCA 1 fader is moving the faders in tracks SYNC, VO, and Drum Hit, while each individual channel strip fader in this group maintains its offset from the others.

Recording Fader Automation for VCAs

You can record automation data to a VCA fader, and all faders in that VCA group will follow even though they're not actually automated themselves. This makes it easy to record complex automation involving multiple faders when you still might want the freedom to finely adjust each individual fader later on.

Nesting VCAs

VCAs can also be "nested," where one or more VCAs can be controlled by yet another VCA. To nest a VCA, simply assign the VCAs you want have controlled to yet another "master" VCA.

Arm, Solo, and Mute Buttons

These controls are identical to the controls found on the track header of each timeline audio track.

- **Record Arm:** Enables a track for recording when the Record button on the transport is engaged (highlights red when enabled).
- **Solo:** Lets you mute all other tracks in order to play a track you need to focus on in isolation (highlights green when enabled).

  If Solo is enabled for multiple tracks, all soloed tracks will play, and all non-soloed tracks will be muted.

  Solo status affects rendering, so if one or more tracks are soloed, the muted tracks won't be output or rendered.
- **Solo Safe:** Command-Shift-click a Solo button to put it into Solo Safe mode (highlights blue when enabled).

  Channel strips set to Solo Safe always play even if Solo is enabled for other tracks.

  Solo Safe can be useful for effect returns busses with effects like reverb where you may want to hear the reverb when tracks feeding it are soloed.
- **Exclusive Solo:** When active, clicking the Solo button on a track takes other soloed tracks out of Solo mode. This means only one track can be soloed and heard at any given time, which is useful if you want to compare audio sources, to hear sonic differences when comparing levels or processing.

  NOTE: Soloing a track in Exclusive Solo mode will not affect a track that is in Solo Safe mode. If you want to include that track, you need to manually deactivate the Safe Solo button first.

  Disabled by default, Exclusive Solo can be enabled by selecting it in the Fairlight menu. You can also map a key command to this function in the Keyboard Customization dialog.

  For more information on Keyboard Customization, *see Chapter 4, "System and User Preferences."*.
- **Mute:** Turning on Mute disables audio playback from that track (highlights orange when enabled). This affects rendering, so if one or more tracks are muted, they won't be output or rendered.

The channel strip's Record Arm, Solo, and Mute buttons

TIP: You can click a button and drag across multiple channel strips to turn that button on or off for multiple tracks easily.

Fader Controls

Each track's vertical fader lets you control the level that's output by that track, either by using your mouse, or using a physical fader of your Fairlight console or third party control surface. If you're working with a console, then the onscreen faders serve as a visual reference of what levels are set.

- **dB Indicator:** Numerical at the top of the track indicates the volume, in decibels, that track is currently set to.
- **Fader:** Each track's vertical fader can be dragged with your mouse or other pointing device to adjust the volume of that track and perform automation recording. Dragging up increases volume, dragging down decreases volume. Fader handles turn red while you record level automation, and they turn green when automation has been recorded for that track.

Methods of adjusting channel faders:

- **To change level:** Click and drag any fader up or down.
- **To reset the level to default level of 0 dB:** Double-click a fader's handle. This does not work after you've recorded automation for a track, unless you erase the automation first.

A Fader in
the Fairlight Mixer

Metering Options

DaVinci Resolve has a variety of metering options that allow you to tailor metering to your workflow. The settings appear in Project Preferences > Fairlight on the Audio Metering pane, but they affect mixer, Fairlight effects, or master metering on the Cut and Edit pages.

Level Metering Options

You can chose the response characteristic of the level meters for channel strips and Fairlight FX.

The Meter Type dropdown allows you to choose between IEC 60268-18, Digital VU, and Custom response characteristics. Both meter types have separate “hold and fall” metering, allowing you to see the highest peak that is reached.

- **IEC 60268-18:** A digital PPM-type meter with reference standard of -18 dBFS, a fast response to peaks, and a slower release characteristic. This is the default in DaVinci Resolve and is used in all Blackmagic Design software and hardware products.
- **Digital VU:** A dual-value meter, showing the peak level as a single segment with fast ballistics, and the RMS (volume unit) as a bar graph. It has a far faster quasi linear decay characteristic, making it easy to monitor average levels while allowing sounds with quick transients and decays to be more easily tracked. This option can be best for audio editing and mixing.
- **Custom:** Allows each aspect of the meter response to be chosen, including level detector, scale, peak, deck, and peak indication.

Pre-fader Metering

By default, “Pre fader metering on tracks” is unchecked (disabled), setting the metering on channel strips to be post (after) the fader level and mute button. For example, if the source audio file has peaks that are hitting -2 dBFS, and the channel fader is lowered from 0 to -10, then the peaks that show on the meter will now be at -12.

When pre-fader metering is on, the metering point is set to be before the fader, and is not affected by the fader’s position. However, the meter is affected by clip gain settings or key framing as these level changes occur before the clip’s signal enters the mixer’s signal path.

With pre-fader metering, you could lower the fader to be fully off (minus infinity) and the meter will still read the level of the source signal. This allows you to always be aware of the source signal and what it is doing before being altered by mixer’s controls or processing.

Many video editors prefer to work with post-fader metering, but most audio mixers prefer to work with pre-fader in order to be aware of what the actual source level is at any time.

Solo and Pre-fader Metering

When pre-fader metering is enabled, soloing one or more tracks will show a lighter “ghost” version of meter activity on non-soloed tracks, allowing you to always see audio levels on tracks that are muted by the soloing process. This makes it easy to focus on tracks that are actually audible while still seeing activity on those that are not.

If pre-fader metering is off (the default), when one or more tracks are soloed, no metering occurs on tracks unsoloed tracks.

Pre-fader metering with light shaded meters on non-soloed tracks

Target Loudness Level

Allows the target loudness level in LUFS for the master Loudness meters to be set to your desired output target level. For example, DaVinci Resolve's default loudness standard target is -23 LUFS, but the YouTube target LUFS specification is -14 LUFS. If -14 LUFS is set, the "0" mark on the loudness meter scale moves to this level, allowing you to focus your master mix levels towards that loudness standard.

Bouncing Audio

Bouncing audio refers to mixing and rendering audio from one or more Timeline tracks onto another track of the Timeline, in the process "baking in" processor intensive effects and complicated or intricate audio edits to create a new continuous piece of audio media. The bounced file is written to the directory location specified by the Project Settings > Capture and Playback panel > "Save clips to" field.

There are two commands available for bouncing audio on the Fairlight page:

- Timeline > Bounce Selected Tracks to New Layer
- Timeline > Bounce Mix to Track

To use Bounce Selected Tracks to New Layer:

1. Set In and Out points to define the range of the Timeline you want to bounce. If you don't do this, nothing will happen.
2. Command-click the track headers or mixer channel strips of all tracks you want to bounce in order to select them.
3. Choose Timeline > Bounce Selected Tracks to New Layer.

   The audio on each track is processed and rendered and appears as the top layer of audio on that track. While View > Show Audio Track Layers is turned off, it will appear as if the new bounced audio is the only clip on that track. However, the original audio (with any unrendered clip-based effects) is still available as the bottom of the stack of layered audio on that track; turning on View > Show Audio Track Layers will reveal this.

   The bounced audio is a new audio media file that's written to the directory location specified by the Project Settings > Capture and Playback panel > "Save clips to" field.

To use Bounce Mix to Track:

1. Choose Timeline > Bounce Mix to Track. The Bounce Mix to Track window appears, showing all busses that are currently available.
2. In the Destination Track column, set which mixes you want to bounce by choosing either New Track, or choosing a specific existing track from the dropdown menus.
3. Click OK.

   The specified mix is processed, mixed, and bounced to the specified track as a new piece of audio. This creates new audio media that's written to the directory location specified by the Project Settings > Capture and Playback panel > "Save clips to" field.

TIP: There's also a Bounce Audio Effects command in the contextual menu of audio clips in the Timeline that have clip-based audio effects applied to them. For more information, *see Chapter 177, "Audio Effects."*

For more information on exporting clips, ranges, and files, *see Chapter 172, "Editing Basics in the Fairlight Page."*

Third-Party Control Panel Support for Mixing

DaVinci Resolve supports HUI- and MCU-compatible third-party mixing control panels with up to eight faders, such as the Mackie MCU Pro Control Surface, connected via USB MIDI, and selectable in the Control Panels panel of the Resolve System Preferences. Supported basic panel controls that correspond to Fairlight features at the time of this writing include the following.

Transport controls including:

- Rewind (REW)
- Fast Forward (FF)
- Stop (double-press the Stop button for Home in the Timeline)
- Play (double-press the Play button to "play again")
- Record (press Record+Play to begin recording if one or more tracks is record-enabled)
- Jog control (Press SCRUB and rotate the jog wheel)

Channel Strip controls including:

- Rotary controls for panning, with Rotary Value display and Rotary touch
- Alphanumeric Track Name display
- Record button to record-enable tracks (only works if an input is patched to a track input)
- Solo, with a double-press selecting or de-selecting that track
- Mute
- Select to select the track corresponding to that channel strip
- Fader control and optional Level display
- Channel and Fader Bank buttons to move left and right among banks of channel strips
- Double-press the Fader Bank Left button to move the playhead Home in the mixer (track 1)
- Double-press the Fader Bank Right to move to the Master channel strips

Marker buttons:

- Marker to add a marker
- Pressing the Marker+Stop buttons sets Home
- Pressing the Marker+FF/REW buttons jumps the playhead forward or backward

Additional supported controls for control panels that have them include:

- Master Solo clear/restore
- Undo (pressing the Undo+Option buttons does Redo)
- Arrows to move the selection
- Zoom horizontal and vertical controls
- Audio Tracks, to turn Automation On/Off
- Write/Trim/Touch/Latch switches
- Nudge controls
- Cut, Copy, and Paste

Monitoring controls include:

- Level control
- Dim
- Mute
- Alt Speaker

For more information on third-party mixing control panel support, see the Blackmagic Support site at https://www.blackmagicdesign.com/support/family/davinci-resolve-and-fusion.

Chapter 175

Mix Automation

The Fairlight page provides straightforward, flexible, and powerful automation capabilities for audio mixing.

Automation data can be created graphically by drawing automation changes, or by recording on-screen mixer or effects controls movement and changes, using a mouse or Fairlight control surface. You can even create panning automation based on the movements of on-screen people or objects in the Fairlight Viewer.

Once recorded, mix parameter automation for any control type—faders or sends, panning, or effects—can be played back in perfect sync with the audio and video.

This chapter covers automation mixing using the combined controls of the on-screen mixer and timeline.

> For more information on basic mixing operations, *see Chapter 174, "Mixing in the Fairlight Page."*

Creating Mix Automation

The Fairlight page includes a comprehensive toolset for creating and editing mix automation. You can draw automation data, or record mix changes by moving on-screen controls, or you can use IntelliTrack-powered Audio Panning to Video, which writes panning automation based on the movements of people or objects in the Fairlight Viewer. Yes, this really is "a thing."

Why Use Track Automation?

If you're a video editor, you may be more familiar with using clip-based automation to make changes to your audio mix, but this approach has limitations. Sometimes there are global changes you may want to make to a track over the timeline or want to adjust groups of tracks at once *see Chapter 176, "Track Groups."*

When working with time-based effects like reverb or a repeating delay, you may want to dynamically adjust the level of "trails" as the track evolves. For example, you may have a scene that changes perspective from a larger space to a smaller one, and the room ambience or tonal quality of the dialogue needs to change over time as the characters move through the scene.

This is where track automation techniques (whether drawing or recording the movement of controls) can be powerful and creatively inspiring.

What Can Be Automated

Automation can be recorded for nearly every control in a Mixer channel strip, including the fader, sends, mute, and panning. You can also automate audio plugin parameters as well.

Audio Panning to Video

IntelliTrack-powered Audio Panning to Video accelerates creativity by automatically tracking people or objects in the Fairlight viewer to generate pan automation that matches their on-screen movements with the precision afforded by Resolve's state-of-the-art object tracking engine.

Drawing Automation

If you're a video editor or audio creative, drawing mix automation data may be more straightforward in many contexts, when making static or ramped level changes or switched changes to controls such as a mute button, especially if you are using a mouse without the benefits of using Fairlight hardware control.

> For example, trying to finesse a real-time "performance" of fader movements or effect parameter changes, you could select a timeline range and mute several tracks at once, "carve out" fixed level boosts or drops on tracks at the exact point you want them to occur based on an on-screen event or dialogue, or slowly increase the strength of a reverb applied to foley footsteps as a character walks into a long, dark cavern.
>
> When drawing automation, you don't need to pay attention to the various Fairlight automation recording modes or control enables/disables for the automation parameter you want to create or edit; you can just draw or adjust your automaton data in the corresponding track "lane" on the Timeline.

Recording Automation

You can also create mix automation by recording real-time on-screen fader, control movements, or plugin parameter changes during playback. Afterwards, your “performance” can be accurately played back. Another advantage of recording your automation is that you can intuitively “perform” the changes against the picture as actions occur.

In this way, you can create a dynamic mix where different audio levels, pan, EQ, dynamics, and audio processing settings change over time to fade music up or down against effects or dialogue, pan the sound effect of a car driving by from one speaker to another, or gradually increase the strength of a reverb effect as your character walks into that long, dark cavern.

While the recording of keyframe automation is commonly associated with either the on-screen mixer or the Fairlight console, you can also record automation using controls found in the Inspector, or using the controls of the Pan, EQ, and Dynamics plugin effects, thereby enabling you to record automation for the various audio effects that you’ve applied to a track.

Drawing Mix Automation

Automaton can be drawn in the Timeline for any parameter by globally enabling automation recording and playback, viewing a parameter to be automated, then drawing the automation in the Timeline.

Enabling and Viewing Automation

The Toggle Automation button, to the right of the transport controls, turns automation recording and playback on and off. It must be enabled to draw or record track-based automation and to see busses on the Timeline.

Toggle
Automation button

TIP: You can quickly enable/disable automation safe on or off for a selected group of channel strips, or to all channel strips, by holding down the Option key (Mac) or the Alt key (Windows) for all selected tracks or Command-Option (Mac) or Control-Alt (Windows) for all mixer channel strips prior to performing the operation. These shortcuts can save a lot of time in your workflow.

Automation View

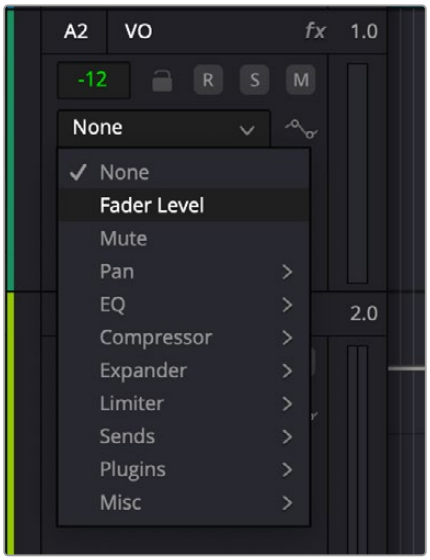
Audio tracks normally display an arrangement of clips on the Timeline (“Clips View”).

In Clips View, clips can be placed or edited, and clip gain for individual clips can be adjusted, *see Chapter 173, “The Fairlight Inspector.”* Effects can also be added to clips, which can be managed in the Inspector.

Tracks can also show an Automation View, which appears when the automation button is enabled. When active, a dropdown menu appears under the track controls in the track header. By default, the menu will display “None,” indicating you are working with clips only; no automation data will appear.

Fairlight Automation View showing “None”

Clicking on the dropdown menu allows you to choose an automation parameter to view or edit. Choices are included for all parameters that can be controlled on a track, including fader, sends, pan, mute, and built-in dynamics and EQ as well as AU or VST plugin effects.



Fairlight Automation View menu choices

For a faster workflow, you can right-click the Mixer channel control or parameter on a Fairlight FX plugin, supported Audio Unit, or VST plugin you want to view or edit.

Once a parameter is chosen, the automation view changes so that the focus is on editing track automation data rather than manipulating clips. The clips darken and the automation data line is shown in light gray. When automation is drawn or recorded for the parameter, the line will change to bright green.

NOTE: When in Automation View you can still move and trim clips, but cut/copy/paste and delete operate on automation keyframe data only. When in Automation View, timeline-based clip gain keyframe adjustment is not available, but overall clip gain can still be adjusted using Volume slider in the Audio tab of the Inspector.

Vector-based Automation

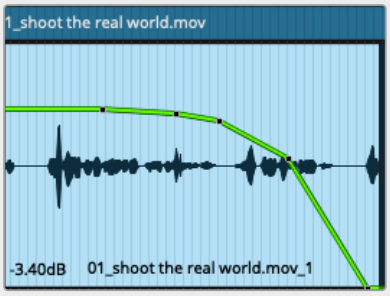
Audio keyframe automation is vector-based, so levels will smoothly ramp between any 2 points on the Timeline based on the direction of the change in control value and the time between the points.

For example, if you have a single keyframe setting fader level to 0 dB that occurs at 01:00:20:00 on the timeline, and then add a point at at 01:00:28:00 at -10.5 dB, the level will change smoothly between 0 dB and -10 dB over the 8 seconds between the 2 points.

This allows you to draw individual keyframes to quickly construct different transition shapes, such as fade-ins or fade-outs, with just a few points, or adjust them up or down by specific amounts quickly and easily.

Creating Curves

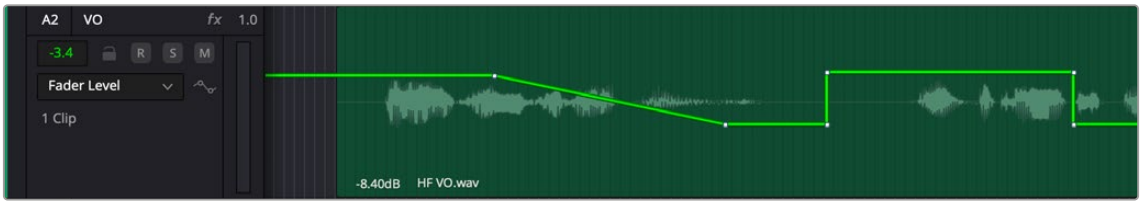
Keep in mind that audio automation keyframes are not Bezier keyframes, so they only let you create a single level adjustment at that point in time. If you make a large adjustment with only a single new keyframe, you can end up with an abrupt level change, or level changes that don't have a curve you may want (exponential changes can be particularly useful on fade ins or outs to get a natural result). You can create convex or concave shapes when drawing by adding just a few keyframes to create your curve, or you can perform the change exactly as you want by recording the automation (see "Recording Mix Automation" later in this chapter).



A fade out transition with 5 keyframes for an exponential shape

Track Automation Line

Audio automation on a track is represented by a line that extends over length of the Timeline, called the automation line, or "curve." The level of the line can be changed by dragging, entering keyframes one at a time, or using the Pencil tool to draw a series of keyframes.



Automation line for fader level showing multiple keyframes

- **Sample Accuracy:** Audio keyframes allow creation of precisely placed parameter changes on timeline tracks. On the Fairlight page, audio keyframes are sample accurate, meaning they can be placed at any sample location with sub-millisecond precision, allowing more precision than keyframe handling on the Cut and Edit pages. However, sample-accurate audio automation data created on the Fairlight page can be accurately played back on the other pages.

Sample accuracy is important when working to picture as the location of audio events often does not fall on exact frame or sub-frame boundaries.

Working with Audio Keyframes on the Timeline

To draw automated changes to any audio control:

- Enable the Automation button to see Automation View on all audio tracks.
- On the track(s) where you want to create automation, choose the parameter you wish to automate in the Automation type dropdown menu in the track header.
- Using Focus Mode's Multi tool allows you to draw automation using the up/down arrow cursor (to adjust an overall curve), enter or delete keyframes one a time using modifier keys, create different curves depending on individual keyframe position, select and delete a range of keyframes, and more.

Adding and Deleting Individual Keyframes

Managing keyframes on the automation line is nearly identical to working with clip gain.

For more information *see Chapter 173, "The Fairlight Inspector."*

- **To add a keyframe:** Hold down the option key and a plus sign appears. Click to place a keyframe on the automation line.
- **To remove a keyframe:** Hold down Command-option and a minus sign appears. Click on keyframe to delete it.

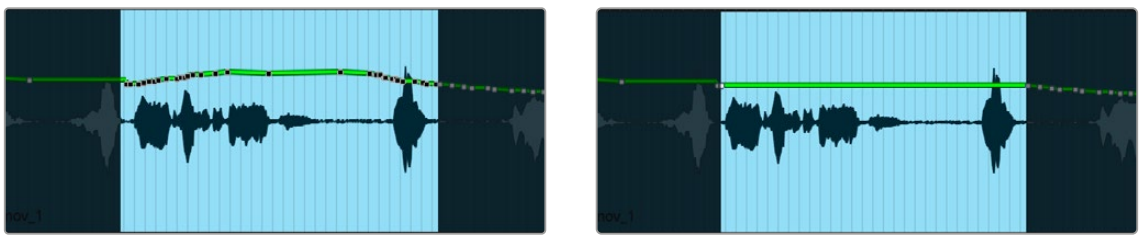
TIP: You can quickly flip between Clips View and Automation View using the keyboard shortcut F4. This can be changed by using the DaVinci Resolve > Customization dialog.

Editing Mix Automation Curves

Using Edit Operations

Normal editing operations such as cut, copy, paste, delete, and nudge can all be used on automation keyframe data. When automation data is cut or deleted, the value at either end of the selection is preserved.

Nudging can be very useful when fine-tuning the location of automation events.

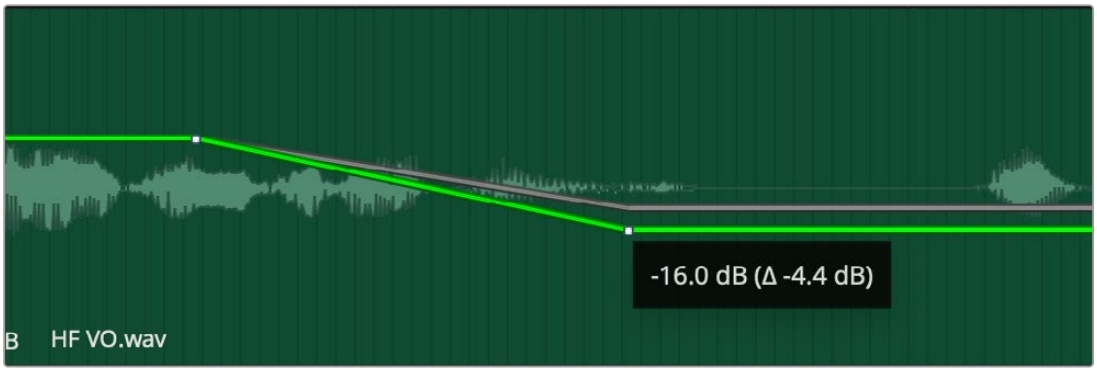


Before and after cut or deletion

Adjusting the Automation Line

Once one or more keyframes are on the automation line, the resulting curve for the entire track can be adjusted. Individual keyframes can be edited up or down using the same techniques as with adjusting clip gain; the whole line can be adjusted, or a selection can be affected.

If you adjust the last keyframe on a line with multiple keyframe points, the line will change from that point onwards to the newly set level.

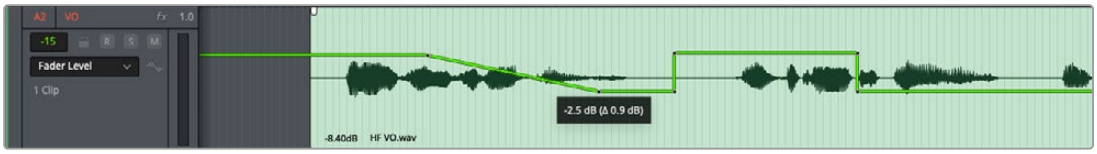


Adjusting an individual keyframe changes the line from that point onwards.

Adjusting the Entire Line

To adjust the entire line:

- With automation view enabled, click anywhere within the track, and select all automation data on the curve by choosing Command-A.
- Position the cursor close to the line and and the dual arrow cursor appears, allowing the level of the entire line to be adjusted.



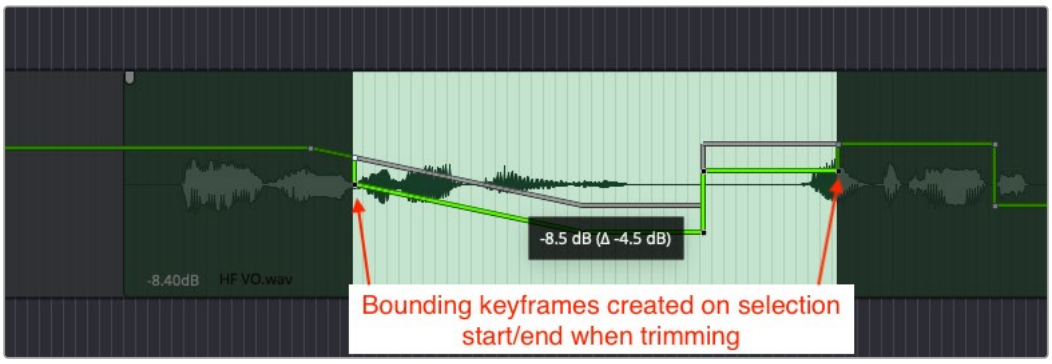
Select all automation to adjust the entire line

Adjusting a Selected Range

You can perform adjustments to only a specific range of the automation curve. This can be useful when you want to make “snapshot” changes for a specific scene.

To adjust only a selected range:

- Use the Focus Mode Select tool (I-beam cursor) to select the range you want to affect.
- Position the mouse close to any area of the line, and the up/down arrow cursor appears.
- Trim the line up or down. A tooltip will appear showing the current value and a delta to the original value, so any difference in a control’s value can be seen.
- At the bounds of the selection, “bounding keyframes” are automatically created, so the level at the edge of the selection is preserved.



Trimming a selected range of the automation curve

TIP: Hold the Shift key when adjusting levels to maintain precision. When adjusting fader levels this allows .1 dB accuracy, even when working with small track heights.

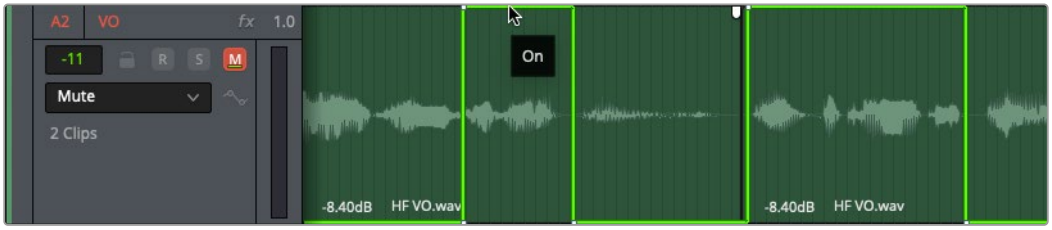
Drawing Automation with the Pencil Tool

The Pencil tool allows automation keyframes to be drawn freely:

- Choose the Pencil tool in the Automation toolbar, or when in Focus mode, hold down Option-Shift to temporarily switch to the Pencil tool.
- Click the mouse and drag to draw keyframes in either direction.

Automating Switched Controls

Some automation parameters are switched (i.e., they have only fixed states). Examples of this type of control are mutes (on or off). When adjusting switched automation, keyframes can only be at the bottom end of the Automation view or the top.

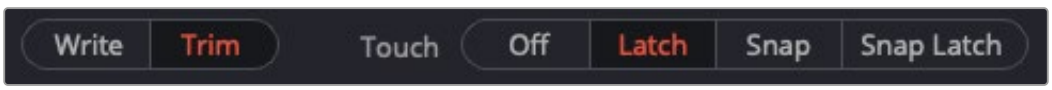


Mute automation showing on and off states

Trimming Automation from Unity in the Mixer

Trim mode supports automation trimming from unity (Fader set to 0) in the Fairlight mixer by following the steps below:

1 On the Automation toolbar, set the Automation mode to Trim.



The Automation toolbar - Trim mode

2 Choose a Touch mode (Latch, Snap, or Snap Latch).

3 Click the Automation Arm button on the mixer channel or tracks you want to trim. The faders on the armed mixer channels will turn yellow and snap to zero, and the dB Indicator above each armed fader will read Δ0.0dB.

> **TIP:** You can either Command-Option click the Automation Arm button to trim automation on all tracks or Option-click the button to trim automation for a collection of tracks or mixer channels you've selected.

Mixer faders set to trim automation from unity

4 Begin playback and move the fader above or below Δ0.0dB. The automation curve will be trimmed, and the dB indicator will display the amount of trim as a plus or minus (+/-) value.

If you've chosen Snap mode, the fader will return to Δ0.0dB based on the Glide time set in Preference > User > Fairlight > Automation.

Audio Panning to Video

Audio Panning to Video uses DaVinci Resolve's state-of-the-art object-tracking engine to help you quickly generate precision panning automation based on the movements of people and objects in the Fairlight Viewer.

Audio Panning to Video offers Automatic and Manual modes of operation.

Automatic Tracking

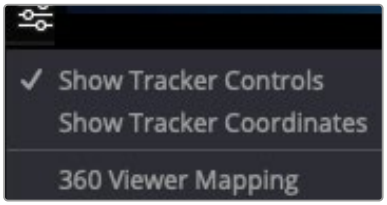
In Automatic Tracking mode, you can select a person or object on screen, and DaVinci Resolve will automatically process the related movement data across a selected timeline range, and then generate the automation data.

To enable and use Automatic Tracking:

1 Click the Toggle Automation button to the right of the transport controls.

Toggle Automation button

2 Click the Fairlight Viewer tools menu and choose Show Tracker Controls.



Fairlight Viewer Tools menu

The Tracker Controls will appear along the lower edge of the Viewer, and you'll see an Auto Tracker Object on screen.

Tracker controls

Audio Tracker Object

You can also select Show Tracker Coordinates, which provides an alpha-numerical representation of the tracker's current on-screen position.

Audio Tracker Object
with Coordinates

3 Select the target track you want to write panning automation to, and use the I-Beam tool to select the Timeline range you want the tracking to work on.

Range Select tool

NOTE: Auto-tracking will not occur unless you select a Timeline range.

4 Click the Auto button in the Tracking Controls section to activate Auto Tracking.

5 Based on the panning movement you want to automate (horizontal or vertical), click the Left-Right (L–R) or Down-Up (D–U) button.

TIP: The Front-Back (F-B) button is only available when the Auto button is off.

6 On the target track, click the Automation dropdown in the Track Header, then followed by Pan > L/R Pan or Pan > U/D Pan to match your selection in the previous step.

7 Move the Auto Tracker Object on top of the on-screen object or person you want to track.

8 Click the Track button to begin the Auto-Tracking process.

9 Start playback to check your audio track. It should follow the object or person you selected for tracking.

TIP: If the track is more complex, for example, a person who is changing their position relative to the camera or may have moved out of frame, you may need to do your tracking in sections.

In this instance, you can select an area that wasn't tracking well, move the tracker object into position, and track over the problem range to redo the track for that portion.

Manual Tracking

Manual mode lets you create keyframes based on the Playhead position on the Timeline, and DaVinci Resolve will smoothly vector between the keyframes like any other automation curve data.

To enable and use Manual Tracking:

1 Click the Toggle Automation button to the right of the transport controls.

2 Select the target track that you want to write your panning automation to.

3 Click the Video Viewer tools menu and choose Show Tracker Controls.

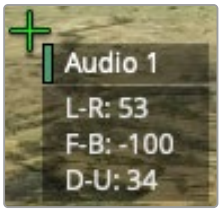
The tracker controls will appear along the lower edge of the Viewer, and you'll see a Tracker Object on screen as a simple crosshair.

Tracker Controls manual mode

Manual Tracker Object

NOTE: The Tracker object will not appear onscreen unless an audio track has been selected.

You can also choose to Show Tracker Coordinates.



Manual Tracker Object with Coordinates

4 Ensure that the Auto button is inactive in the Tracking controls. Now you're in Manual Tracking mode.

5 In the Tracking Controls, click the panning control you want to automate: Left-Right (L–R), Front-Back (F-B), or Down-Up (D–U).

6 On the target track, click the Automation dropdown in the Track Header, then Pan > L/R Pan, Pan > F/B Pan, or Pan > U/D Pan to match your selection in the previous step.

   You can increase the track height if the Automation dropdown is not visible.

7 Move the Playhead to the Timeline location where you want the automation to start.

8 Write a keyframe at the current position in the video by Option-clicking the Viewer at the location where you want to place the sound at that moment.

   A corresponding Automation node is placed at the Playhead position on the automation line.

9 To add another keyframe, move the Playhead to another point in your timeline, Option-click the on-screen person or object you're tracking.

   The Tracker Object jumps to that position, a keyframe is written, and a new Automation mode is added at the Playhead position.

DaVinci Resolve will smoothly vector between the keyframes, as with any other automation curve data.

10 Continue creating keyframes at desired positions by repeating the previous step.

11 To create a "bounding keyframe" to lock a position that holds the automaton line before moving to a new position, Option-Shift-Click on a location.

12 Start playback to check, and if needed, adjust your automation.

Recording Mix Automation

Recording mix automation uses many of the same techniques as drawing but allows you to capture a performance where you are moving the controls you want to automate. This can be flexible and creative as you "perform to picture" to get the results you want.

To get started, you'll need to ensure that Automation recording is enabled (see "Enabling and Viewing Automation" above) and that one or more parameters are enabled for automation recording.

Clicking the Automation Controls button displays the Automation toolbar

Automation Controls

The Automation Controls button, to the right of the transport controls, lets you show and hide the Automation toolbar.

The Automation toolbar has buttons for each option that's available for preparing to record automation in your mix.

Automation toolbar options

The Automation toolbar displays the following options:

- **Automation Modes:** Controls how automation data is recorded.

  Write: Records absolute changes to a control's position, replacing any data that was there previously.

  Trim: Records relative changes to a control's position, maintaining relative existing levels created over time, but increasing or reducing those levels overall. This can be very useful when incrementally refining a mix.

- **Touch Modes:** Defines what happens when an automatable control is moved during a mix.

  Off: No automation is recorded.

  Latch: Automation is recorded once a control is moved and continues recording after the control is released until the transport is stopped.

  Snap: Automation is recorded once a control is moved and then smoothly glides back to the pre-existing level at the point it was released, to create a seamless transition.

  At the point where the glide transition ends, automation is no longer recorded unless the control is moved once again while the transport is playing. You can continue to capture additional automation with Snap until the transport is stopped.

  The time for the glide transition can be set in milliseconds in Preferences > User > Fairlight > Automation. The default is 250 ms.

  Snap Latch: A combination of Snap and Latch modes, where faders operate in Snap and all other controls operate in Latch. This can be useful when dynamically changing fader levels through a mix pass are desired, while other controls "stick" when they're moved. It is particularly useful when working with Fairlight mix control surfaces where faders and rotary controls can be changed simultaneously during a mix pass.

- **On Stop:** Defines what happens when entering Stop at the end of an automation pass.

  Event: The last recorded automation value overwrites previous levels to the start of the next available recorded automation data (or event) in that track.

  Hold: Deletes all previously recorded mixing data after what you've just recorded, to hold the last recorded level for the rest of that track.

  Return: The last recorded automation value is interpolated to ramp back to the previously recorded automation values on that track.

- **Enables:** The following buttons let you enable or disable different controls for recording automation.

  Fader: Automates track and bus volume.

  Mute: Automates the mute button.

  Pan: Automates all pan controls.

  EQ: Automates all EQ controls.

Comp: Automates just the Compressor controls in the Dynamics window.

Gate: Automates just the Gate controls in the Dynamics window.

Lim: Automates just the Limiter controls in the Dynamics window.

Sends: Automates the Send controls in the Sends window.

Plugins: Automates all Fairlight, VST, or Audio Unit (AU) plugins.

Misc: Automates Buss on/off, Insert, and Direct Out controls. If a project is using the Fairlight legacy Fixed Bus configuration, it allows automation of fixed bus Main and Sub bus enables.

How to Record Automation

There are two different ways you can set up the recording of automation for levels, panning, EQ, Dynamics, and other audio controls in the mixer.

Recording Automation for Multiple Tracks

You can use the following steps to record automated changes to any audio control in any control strip:

1. Open the Automation toolbar, and do the following three preparatory steps:
   a) Choose whether you're going to write new automation, or trim automation that's already recorded. Write mode is appropriate when you're recording automation for the first time, or when you're overwriting previous automation with brand new values. Trim mode is appropriate when you're making incremental changes to previously recorded automation. Note that Trim mode works as a delta trim system only with fader positions at zero (unity) on Fairlight control surfaces at this time.
   b) Next, choose Touch and On Stop behaviors that are appropriate for the kind of automation recording you need to do.
2. Move the playhead to the beginning of the section of the timeline you want to record automation for.
3. Next, initiate playback using any method (Spacebar, L, Play button, Fairlight or third-party audio control surface), and make whatever adjustments you want to the controls you've enabled automation recording for. As you make adjustments, the affected fader control turns red to let you know you're recording automation.
4. When you're finished, stop playback using any method (Spacebar, K, Stop button, third-party or Fairlight audio control panel). Automation recording stops as well.

Recording Automation for Specific Individual Tracks

You can use the following steps to record automated changes to controls in specifically armed control strips:

1. Open the Automation toolbar, and do the following three preparatory steps:
   a) Choose whether you're going to write new automation, or trim automation that's already recorded. Write mode is appropriate when you're recording automation for the first time, or when you're overwriting previous automation with brand new values. Trim mode is appropriate when you're making incremental changes to previously recorded automation.
   b) Next, set Touch to Off, which disables across-the-board automation recording and requires you to arm specific tracks that you want to automate.

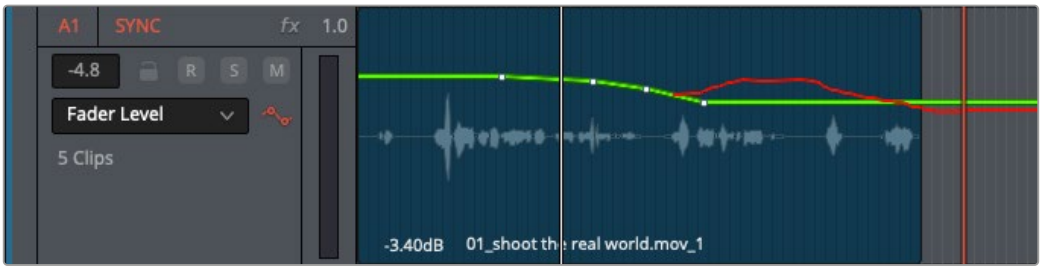
2 Click the automation arm button above the fader of any Mixer track or any track header to which you want to record automation. Even though the Touch control is set to off, moving a control on an armed channel strip will record automation in Latch mode.

The automation arming button above a fader in the Mixer

The automation arming button in the track header

3 Move the playhead to the beginning of the section of the timeline you want to record automation for.

4 Next, initiate playback using any method (Spacebar, L, Play button, Fairlight or third-party audio control panel), and make whatever adjustments you want to the controls for which you've enabled automation recording. While you make adjustments, the affected fader control turns red to let you know you're recording automation. If you're displaying the same automation data in the Timeline that you're recording, you can see the new automation being drawn in real time, in red.



New automation line in red while being recorded

5 When you're finished, stop playback using any method (Spacebar, K, Stop button, Fairlight or third-party audio control panel). Automation recording stops as well. Displayed automation turns green once recording has stopped.

If you don't like what you've done, you can undo and start over, or you can edit the automation using methods described later in this chapter. Or, you can back the playhead up and overwrite automation at any time with new automation.

Automation Preview Mode

Preview is an additional mix automation workflow, specifically for working across scene-based material. When enabled, mix items that are in preview are not controlled by pre-recorded automation, so they respond manually to their controls. These can subsequently be placed into write (or trim) to write actual automation.

Typically, Preview mode is used to audition new mix settings for one particular section of a timeline, while other sections already have recorded automation data. Preview mode prevents pre-recorded automation from moving the controls you are trying to adjust in a targeted section. As soon as you're happy with the new adjustments, they can be written to the targeted section.

Preview mode frees the faders (and other controls) from automation control, and lets you move them freely while you experiment with different levels and settings. Ordinarily, moving one or more controls implies writing automation data for those controls, but entering Preview mode lets you play with the controls as much as you like without committing to anything, only writing automation data when you're ready.

To engage the Preview state on enabled mix items, first enter Preview mode by doing one of the following:

- Toggle Preview in the Automation toolbar.
- Press the Preview key on the Mix page of the Fairlight controller.

Once Preview is engaged:

- Individual parameters can be switched into Preview Touch Latch.
- You can use the AUTO key next to a fader to preview all enabled parameters on a channel.
- You can use the Auto button on the screen mixer strips.
- When you're in Preview mode, all parameters in Preview are indicated by a BLUE automation indicator.

Once in Preview mode, mix items can be placed into write (or trim) by:

- Dropping in manually via the Fairlight > Automation > Punch In menu choice.
- Dropping in manually with the In key on the Fairlight controller.
- Automatically using the Active In and Out points on the Fairlight controller.

  Once enabled for Preview, parameters remain in that state regardless of transport starts and stops. This is different from putting mix items into WRITE, which must be done again after each transport stop.

Other Preview-related operations include:

- Filling a range defined by In and Out points with all parameters currently in Preview.
- Gliding all parameters from their existing values at the Range In point to the Preview values at the Range Out point.

Automation Active Range

The Automation Active Range allows you to set only a specific range on the timeline to record automation to, so that everything outside of that range is "write protected" and will not be disturbed.

- To enable the Active Range, choose Fairlight > Automation > Active Range, where you can mark the Active Range In/Out points, or enable or disable the Active Range.
- Once a range is defined, automation writing will only take place within the range.
- You can set the automation mode you wish to work in (e.g., Snap).

- Once playback begins, all automation data produced prior to the range automatically occurs in Preview mode (without having to enable the Preview switch), up and until you reach the Active Range in point. Once inside the Active range, automation recording will start.
- At the end of the range, automation recording is automatically punched out.
- The Active Range can be disabled by unchecking Fairlight > Automation > Active Range > Enable.

NOTE: Any controls in Read mode will play back their automation regardless of the status of the Active Range.

Active Range shown in the ruler with red bar; Automation data being written within the range

Viewing Automation in the Timeline

Once you've recorded automation for a supported plugin parameter or Mixer channel control, you can select and view it on the corresponding timeline track using one of the methods described below.

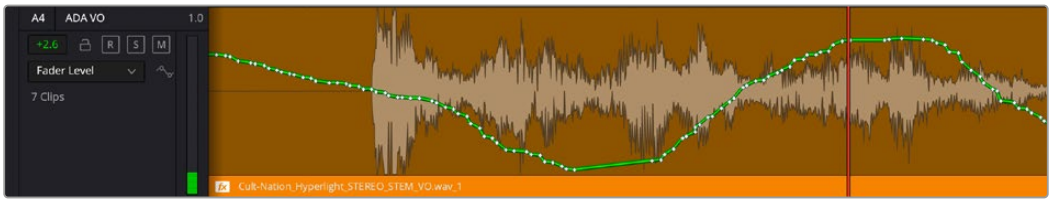
Right-Click to View Automation

Fairlight lets you select and view track automation by right-clicking parameters on Fairlight FX, supported Audio Unit or VST plugins, or Mixer channel controls. The parameter or control name is displayed in the track header, and the corresponding automation curve appears in the Timeline.

This time-saving method is especially useful when automating supported plugins with an extensive parameter list, such as a parametric EQ or mixer channel strip emulation.

The Automation Dropdown Menu

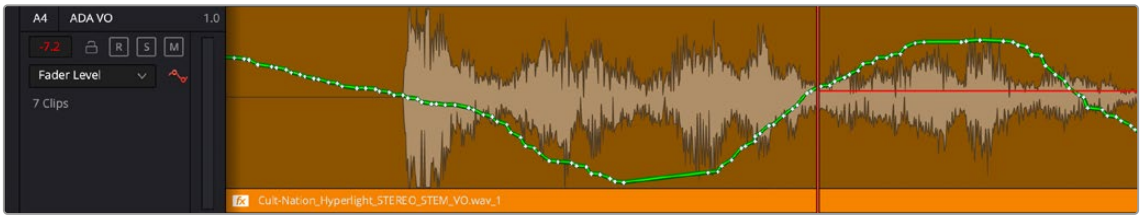
When automation is enabled via the Toggle Automation button, you can use the Automaton dropdown menu on the track header to choose which automation curve to view, with options for Fader, Mute, Pan, EQ, Compressor, Limiter, Aux, Plugins, and Misc controls..



Mixing automation for the Fader shown in the Timeline

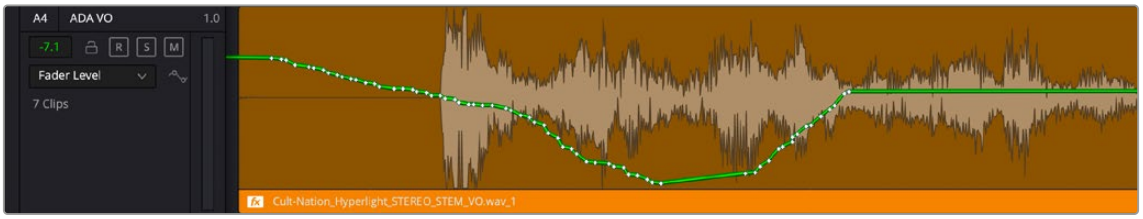
Overwriting Automation

Once you've recorded automation for a particular clip, you can overwrite that automation in subsequent passes. Using either of the previously described methods of recording automation, adjusting the levels of a track control with previously recorded automation displays a red line that shows the new level relative to the previously recorded level.



Setting new levels to overwrite previously recorded automation displays a red line

Pressing play to actually record this new automation will overwrite the previous levels at this new value.



New automation overwrites the previous levels

Automation data can be copied, pasted, and erased under the Fairlight Menu > Automation > Copy/Paste/Erase.

Automation Follows Edit

When editing your timeline, you can choose whether automation will follow the movement of clips or stay locked to its position. This is enabled by default but can be changed by unchecking Fairlight > Automation > Follows Edit.

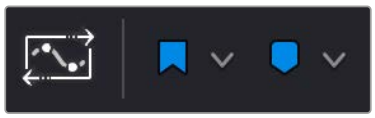
When enabled, anytime you move or edit a clip on the Timeline, the automation you'd written over its range will follow with it, ensuring that as you make changes to the edit, the automation for a given clip range will remain the same.

This is also extremely useful when doing an initial edit of audio clips that contain automation data. For instance, if you have a recurring sound effect that pans left to right, first automate that panning to the audio clip. When this clip is copied through the Timeline it will retain the same panning automation for each new instance. This can be very useful for a variety of edits that require the same automation data for audio clips in a timeline.

Be aware, however, that Automation Follows Edit will need to be turned off when copying and pasting clips or sequences where the automation that has been applied is not relevant to the new edits.

When Automation Follows Edit is enabled, automation data "lives with" the time range it came from. Any of that data, like volume or panning, will travel with clips. So if a complete section has been removed, all of the automation inside of the clips contained in that section are also removed. If a section of clips changes its location in the Timeline, all of the automation embedded in those clips move to the new location on the Timeline with the clips.

When automation is enabled in the Fairlight toolbar, the Automation Follows Edit button will appear.



The Automation Follows Edit button to the left of the Flag button on the toolbar

Editing Automation

When automation is enabled (Toggle Automation button is on), the Pencil tool appears. Combined with the Focus mode, these tools let you edit automation in different ways.

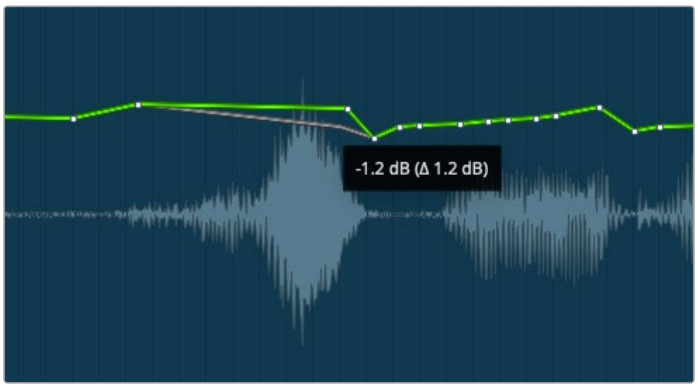
Focus mode provides the main tools used for editing automation. The Pencil appears when automation is enabled (Toggle Automation is on).

Adjusting and Deleting Automation Keyframes

The Focus tools let you adjust automation in two different ways.

Adjusting Individual Keyframes

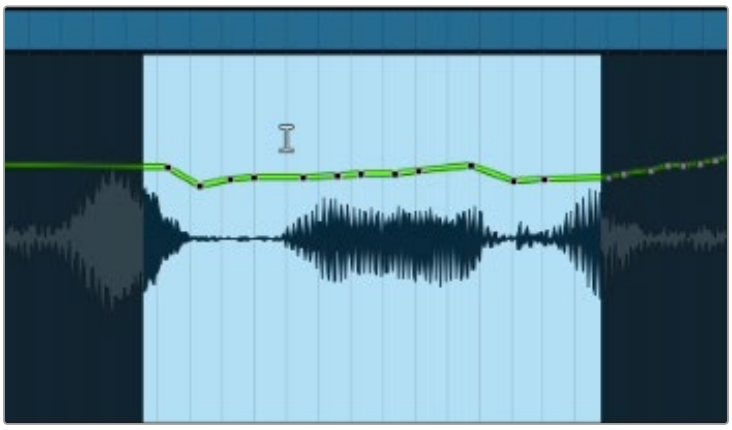
Using the Focus tools, you can click and drag any automation keyframe up or down and left or right (bounded by its neighboring keyframes) to adjust it directly. When zoomed in, this can be an effective way of making precise adjustments. The segment of automation affected by the keyframe being dragged continues to show green to indicate the new curve being created, and a tooltip with the currently adjust value appears, while the previously created data is shown in gray. When you release the mouse button, the curve is adjusted



Single keyframe being adjusted showing prior level in gray

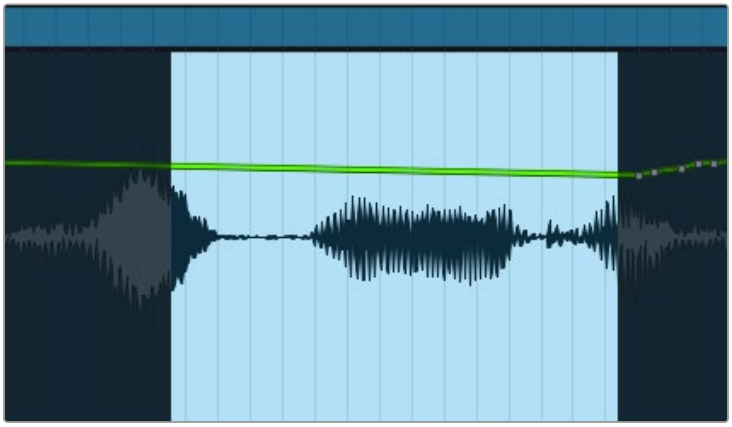
Adjusting and Deleting Multiple Keyframes

You can also use the Focus mode I-beam selector tool to create a selection of select multiple keyframes, or to move or delete them.



Use the Focus mode I-beam selector to select a range of keyframes

If you delete the keyframes in the range, the remaining section of the curve flattens out to fit the first and last keyframe of the selection.



Automation curve after deleting the selected keyframes

Adding and Editing New Keyframes

See "*Working with Audio Keyframes on the Timeline*" earlier in this chapter for more information about working with drawing and editing keyframes.

Clear All Track Automation

If you want to erase all automation on a track or bus, including all send and plugin automation, you can do so by right-clicking the track header and selecting Clear Track Automation from the menu. A new window will appear offering the following options for changing your mind or erasing the automation:

- **Cancel:** To keep your automation data.
- **Reset:** Clear all automation and return all affected controls and parameters to their default settings and values.
- **Hold:** Clear all automation and retain the settings and values of all affected controls and parameters.

Fairlight > Automation Controls

A series of commands in the Fairlight > Automation submenu let you initiate various automation tasks. These commands are:

- **All Read:** Switches all parameters that are in Trim or in Write mode back to Read mode.
- **Punch In:** When Preview mode is on, switches all parameters currently in Preview (blue) into Write or Trim. When Preview mode is off, this switches all Automation-enabled parameters on all selected channels into Write or Trim.
- **Punch Out:** When Preview mode is on, switches all parameters currently in Write, Trim or Preview into Read. When Preview mode is off, this switches all Automation-enabled parameters on all selected channels into Read.
- **Fill Range:** When there is an active In and Out range in the Timeline, the current value of all parameters in Preview will be written over that range.
- **Glide Range:** In Preview mode, “glides” all parameters from their existing values at the In point to the preview values at the Out point of the Timeline.
- **Join Mix:** Lets you manually resume writing automation in Latch mode from the current level and moving to any other.

Automation – Copy/Paste/Erase

The Fairlight > Automation submenu also has special local choices for Copy, Paste, and Erase of automation data. Copy/Paste allows you to do powerful range-based manipulation of automation, or to create a “snapshot” change where all automation data is pasted for a single point in time, allowing all enabled parameters to switch at once to new levels.

Using these commands requires that you choose which automation parameters are affected explicitly by using the Automation Enables controls (the same ones used to choose what automation data is recorded). For example, if you want to affect fader, mute, and pan automation, you must activate the enables for those parameters first. Only the parameters enabled are affected.

NOTE: Clip view or Automation view (any parameter) can be used with these commands; the choice of what is affected is governed by the Automaton Enables, not by the view.

Enables set for copy, paste, or erase of Fader, Mute, and Pan data only

- **Copy:** If there is an active In and Out range in the Timeline, Fairlight > Automation > Copy will copy the automation data of all selected channels and enabled parameters within this range to the clipboard. If there is no active In and Out range, this command copies the data of all automated parameters on all selected and enabled data at the playhead (Snapshot mode).
- **Paste:** Pastes the active range or in point for all automation data copied to the clipboard for Automation-enabled parameters.

  If there is an active In to Out range defined, then the range will be filled with any automation data copied to the automation clipboard using Automation > Copy. If there is no active In to Out range defined, then the automation clipboard is simply pasted in its entirety.

  The contents of the clipboard can potentially target a different channel set and/or with a different target time, just by using a new in point or track selection.

If there is an active In to Out range defined in the Timeline, and the clipboard was in Snapshot mode when the data was copied, then this range will be filled with static values of the snapshot data.

- **Erase:** If there is an active In and Out range in the Timeline, Erase will delete the automation data of all selected channels within the range, obeying all Automation Enable buttons. If there is no range selected, nothing is affected.

TIP: To clear all automation from a Timeline or group of tracks, select the entire timeline range, enable the Automation Enable buttons for the types of automation you wish to clear, and choose Fairlight > Automation > Erase. Alternatively, Fairlight > Automation > Mix List can be used to clear all automation from the Timeline.

Automation – Mix List

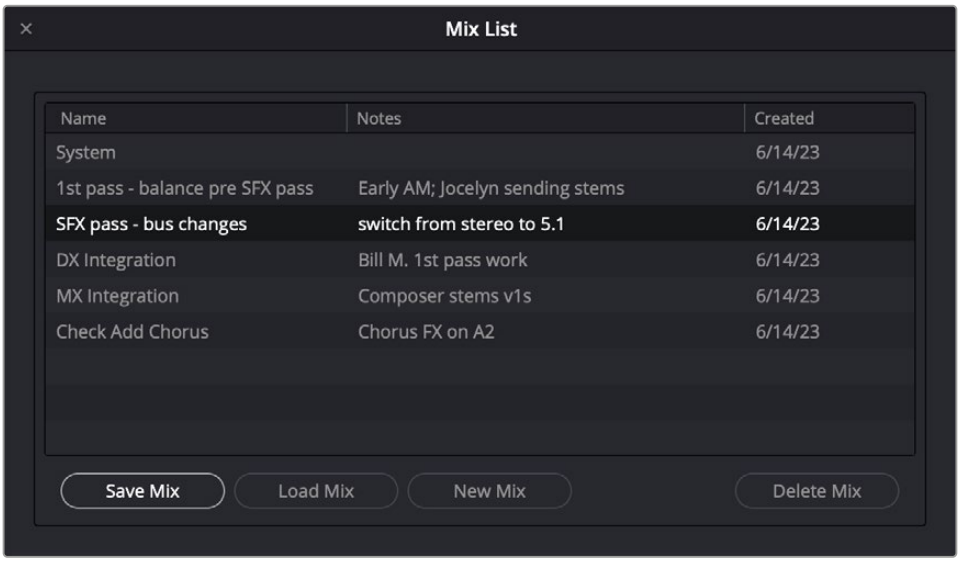
The Mix List allows you to create and manage multiple mix "passes" and complete routing and effects setups for a single Timeline. Each stored mix can have totally different mix automation data that is changing over time, routing, plugin setup, track grouping, etc.

This capability is incredibly powerful and allows a lot of creative freedom for creating different versions of mixes (for example moving between stereo, 5.1, and Dolby Atmos as formats), or between using totally different plugin effects or different creative approaches to the mix itself using all of the automated parameters.

So the Mix List's utility is not limited to storing mix automation data; it can be used to store a dynamic preset of literally anything about the setup of the Mixer.

Keep in mind that the Mix List is particular to a single Timeline and also cannot be shared between projects. However, using the Mix List can be more convenient than saving multiple different versions of timelines or projects.

The Mix List can act as a floating window where you can see the various mixes, or it can be hidden until you need to load or save a new version.



The Mix List Window

Using the Mix List Window

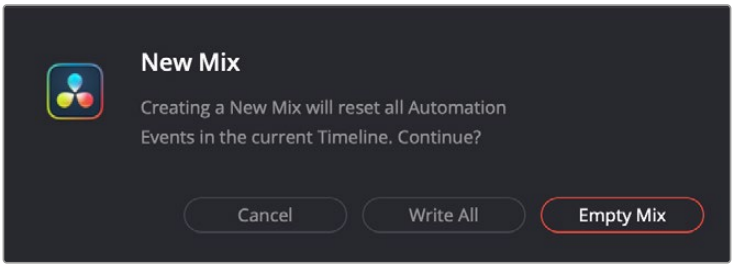
- Set up your mix, including all routing and automation as you like.
- When you're ready to save a mix version, choose Fairlight > Automation > Mix List, then choose "Save Mix" and give it a name, along with any notes you make want to add.
- You can then change your mix automation, any routing, etc. you wish and save a new version, load a different version, or delete an existing mix.

  The "System" preset is an internal system preset that can't be altered; it can be ignored.

The "New Mix" Dialog

For "New Mix" in the Mix List window, a dialog appears with the following options:

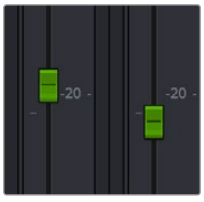
- **Cancel:** Lets you cancel the operation.
- **Write All:** Writes present levels of all controls to their automation curves establishing a baseline "snapshot" of all parameters.
- **Empty Mix:** Clears all automation data from the mix, leaving only the assignments, routing, track group enables, etc. This option offers a simple way to start "fresh" with a mixer setup on a new mix.



New Mix dialog

Playing Automation

After you've automated a mix, playing it back is as simple as moving the playhead to an area of the timeline prior to the recorded automation, and initiating playback. As the timeline plays, the onscreen controls for each automated parameter are shown in green. They move and update to show their recorded levels.



Controls that have recorded automation during playback are shown in green.

Chapter 176

Track Groups

Track Groups let you make adjustments and modifications to your mix across multiple tracks at the same time.

Contents

Editing with Track Groups 3744
Mixing with Track Groups 3744
Creating and Editing Track Groups 3746
The Mixer and Track Groups 3747

Editing with Track Groups

Track groups let you switch focus from individual tracks to groups of tracks, which can range from a small number of tracks to a large multitrack sub-mix group.

When a group is enabled, editing operations apply to all tracks in the group. However, some operations that involve moving clip boundaries or trimming do not.

For example, pressing the Up and Down arrows to navigate to a clip boundary obeys the boundaries of the individual tracks within the group, regardless of their vertical position in the timeline.

Groups can be disabled, allowing you to change focus back to the individual tracks within them. But when smaller groups are “nested” within a larger one, turning off the larger group does not affect the smaller group.

In situations where an edit group contains clips of differing lengths, the group behavior still applies, such that all edits, such as trim, cut, or paste, will follow the group at its present boundaries.

Mixing with Track Groups

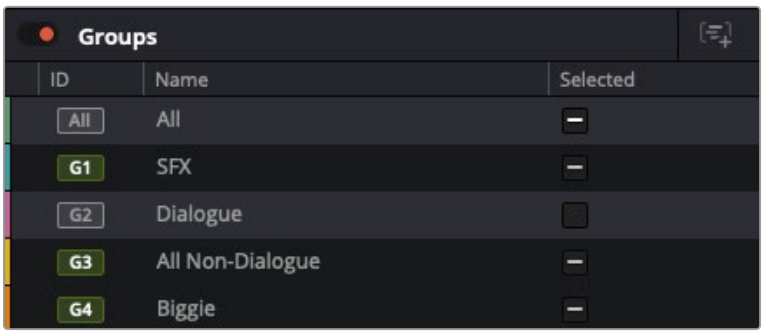
When mixing with track groups, changes to one channel are simultaneously made to all others in the group. This includes fader movements, panning, send levels, automation, and changes to the mute, solo, and record-arm buttons.

NOTE: Plugin controls cannot be added to Mix groups.

Showing the Groups List

Clicking the Groups button in the Interface Toolbar opens and closes the Groups list. If the Track Index or other Index tabs are already open, the Groups list will appear beneath them.

This list remains open when you close the Track Index or click one of the other Index tabs.



Groups list

Groups List Controls

	Group Name: The group name or “ID” appears in this column.
	**Groups Switch:** Toggles all groups on or off, allowing you to switch easily from working with groups to working with individual tracks.
	Selected Checkbox: When checked, all tracks that are members of the group are selected. If some members are selected, a hyphen is shown.
	**Action Icons on Hover:** These icons only appear when hovering over the group row. The Tools icon accesses the Modify Groups dialog, and the Trash icon deletes the group.

The All Group

The All Group contains all tracks Mixer channels, making it easy to perform edit or mix tasks on all tracks at once. This group is always present at the top of the Groups list.

The Selected Checkbox

Clicking the Selected Checkbox adds a checkmark, signifying that all tracks within the group are selected. This makes it easy to add to a current group (shift-clicking to add more members and using Create Group) or control the routing of all selected tracks at once by holding down the Option (Alt Windows) keys while assigning or unassigning.

For example, let’s say we have Group 1 with six tracks and Group 2 with 10. Just click on the Selected checkbox for Group 1, and all tracks in Group 1 are selected. Hold down Shift and click on the checkbox next to Group 2. Now, all members of both groups are selected, and you can create a new Group 3 that contains all members.

- A hyphen (“-“) is shown if only some tracks are selected.
- Clicking the checkbox to remove the checkmark or hyphen deactivates the group.

NOTE: The Selected checkbox operates independently of whether a group is enabled or disabled; it’s a separate control not directly tied to grouping.

Group Key Commands

Activate or deactivate Groups using Command + num keypad 0 key (Control on Windows).

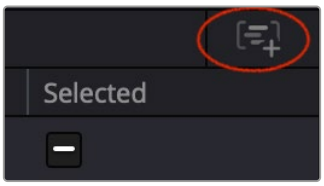
You can use Command (Control on Windows) + num keypad number 1-9 to activate or deactivate the first nine groups.

Use Command (Control Win) + num keypad * key to toggle the All Group.

Creating and Editing Track Groups

To create a track group, do one of the following:

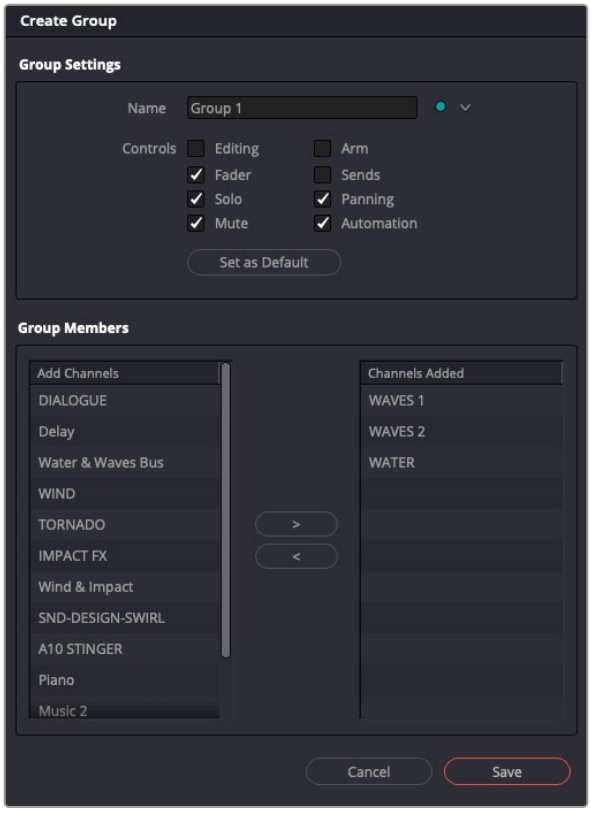
- Select one or more tracks via their track headers in the Timeline. Right-click on any track you want to include in the group and select Create Group. This also works in the Mixer on a channel strip.
- Select one or more tracks via their track headers in the Timeline. Then click the Create Group icon in the upper-right corner of the Groups list.



Create Groups icon

In the resulting dialog, do the following:

1. Type a name for the group. Click the dropdown list to the right of the Group Name field to select a group color.
2. Select which controls you want to include for the group (Editing, Fader, Solo, Mute, Arm, Sends, Panning, and Automation). Click Set as Default to use these selections when creating other groups in the future.
3. Select tracks in the Add Channels column on the left, then click the >> icon to add selected tracks to the group. You can also select tracks in the Channels Added column on the left and click the << icon to remove those tracks from the group.
4. Click Save to save the group.
5. The new group appears in the Groups list.



Create Group - Group Settings dialog

To activate or deactivate a group:

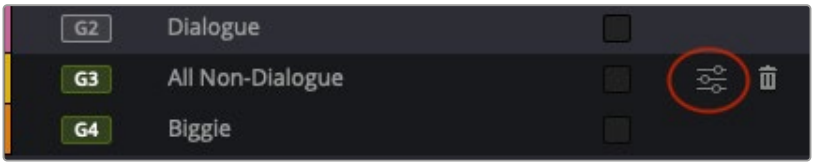
- Select or deselect the group in the Groups list. Selecting a group highlights it, indicating it is active.

To rename a group:

- Double-click the group name in the Groups list.
- Type the new name you want for the group.

To edit a group:

- Hover over the group you want to edit and click on the Settings icon to open the Modify Groups (Group Settings) dialog.
- Make any changes you wish, then choose Save.



Tools icon to launch Modify Groups dialog

To delete a track group:

1. Open the Tracks Index.
2. In the Groups list, hover over the group you want to remove, click the Trash Can icon on the right, and then click the Delete button in the confirmation dialog.

The Mixer and Track Groups

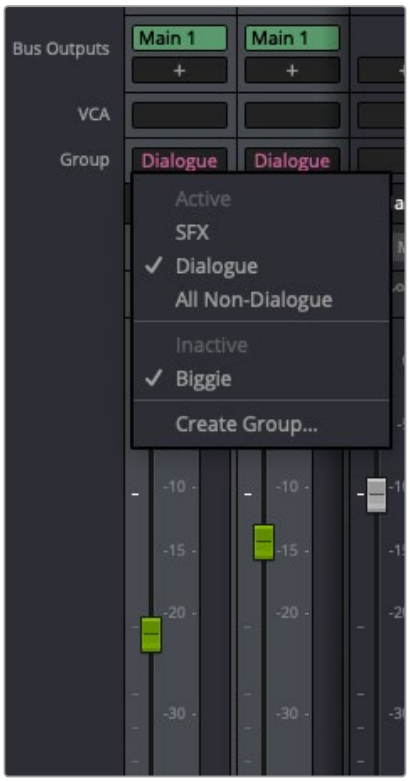
Temporary Override (“Clutch”)

When working on the Mixer, holding down Command-Shift (Mac) or Control-Shift (Windows) and moving a fader or faders within a group allows them to be manipulated independently of other group members (i.e., this is like suspending the group for just the faders that are “clutched”).

Group Management via Mixer Channel Strips

You can also manage group assignment and creation by clicking the Group name section of any channel strip, which opens a menu with the following information and the option to create a new group:

- Active and inactive channel groups
- A checkmark next to the group name the channel strip belongs to, if applicable.



Group menu on a Mixer channel strip

Chapter 177

Audio Effects

DaVinci Resolve includes Fairlight FX audio plugins and support for compatible third-party VST and Audio Unit plugins for use in the Edit and Fairlight pages, which let you add effects such as echo, reverb, noise reduction, and aural enhancement to audio clips, tracks, and busses.

This chapter covers different methods of using these effects on clips and tracks.

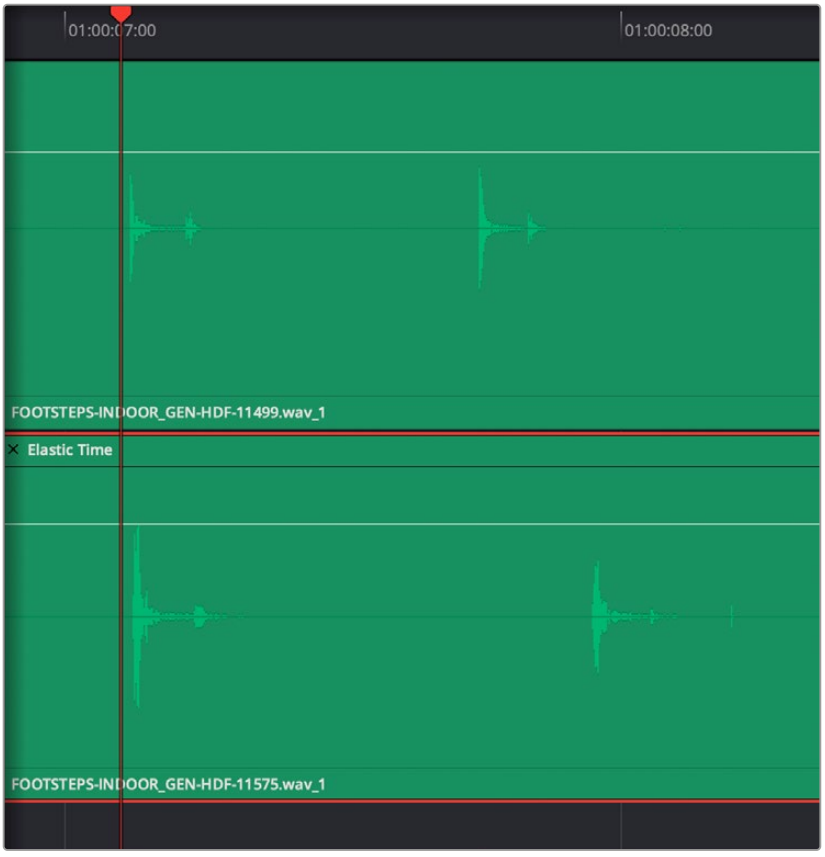
Elastic Wave Audio Retiming

Elastic Wave retiming is a fast and easy keyframe-based way of dynamically retiming audio, squishing and stretching different parts of a waveform to subtly retime audio playback for a variety of reasons, all while maintaining constant pitch. For example, if you're using the audio from another take to replace that of the current take, but the performer's timing is just a little bit different, you can use Elastic Audio to make small adjustments to retime the second performance to match the first.

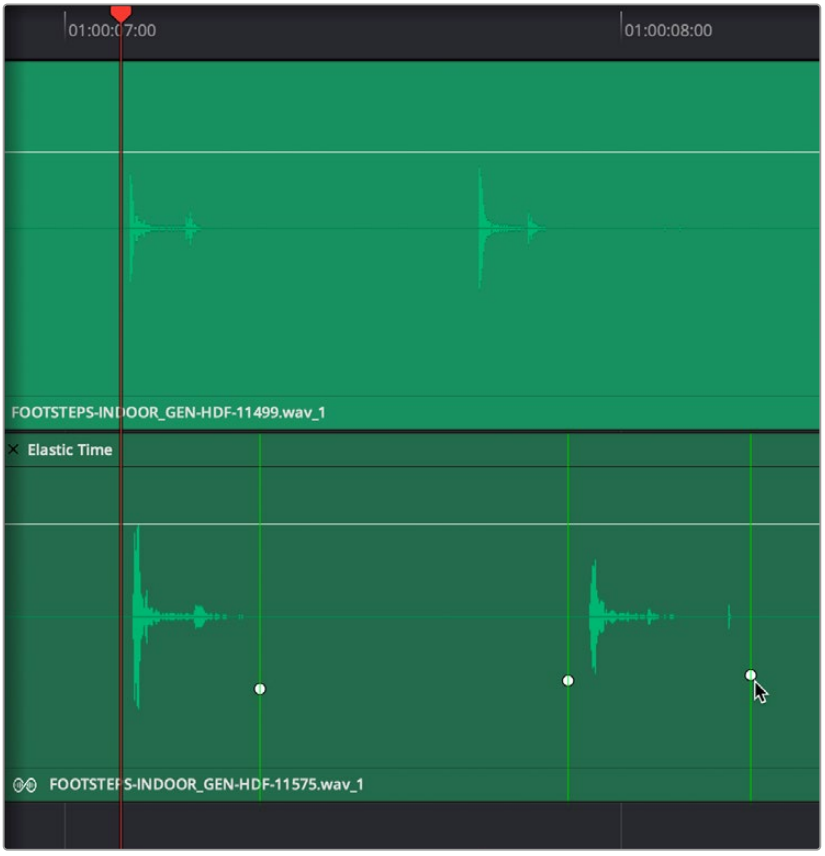
To use Elastic Wave retiming on an audio clip:

1. In this example, two tracks of foley effects have been recorded, and the bottom one needs to be retimed to match the top one.
2. Right-click an audio clip and choose Elastic Wave retiming from the contextual menu to reveal the Elastic Wave retiming controls.



Enabling Elastic Wave

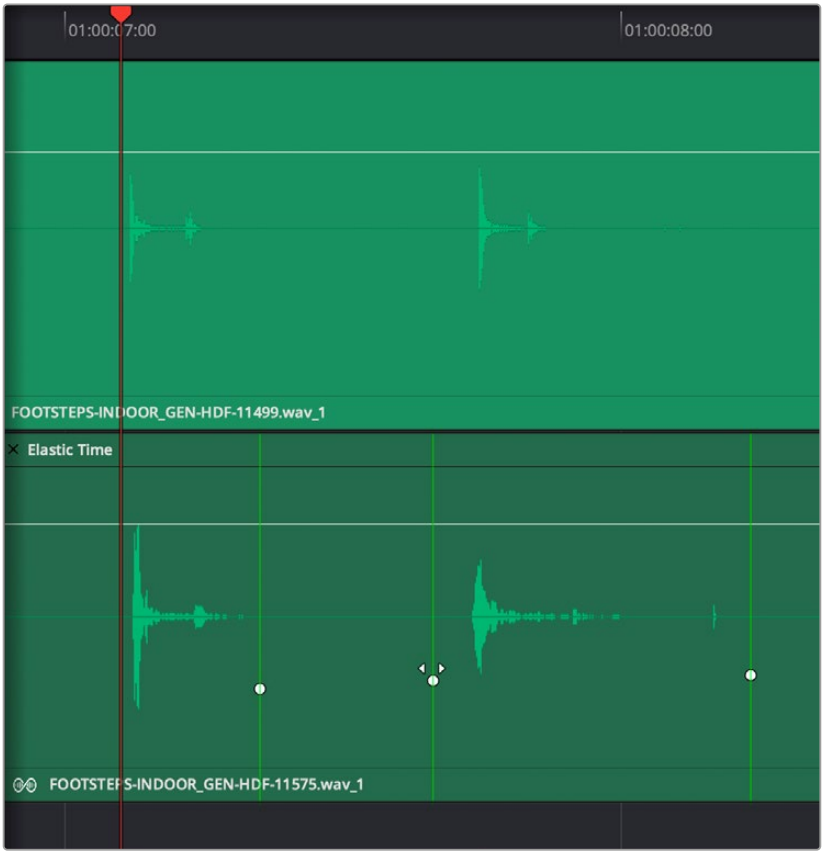
3. Command-click anywhere on the clip to add speed keyframes to parts of the waveform you want to retime by stretching or squishing. You can also place speed keyframes to lock parts of a waveform you don't want to retime.



Adding a speed keyframe with Elastic Wave retiming enabled

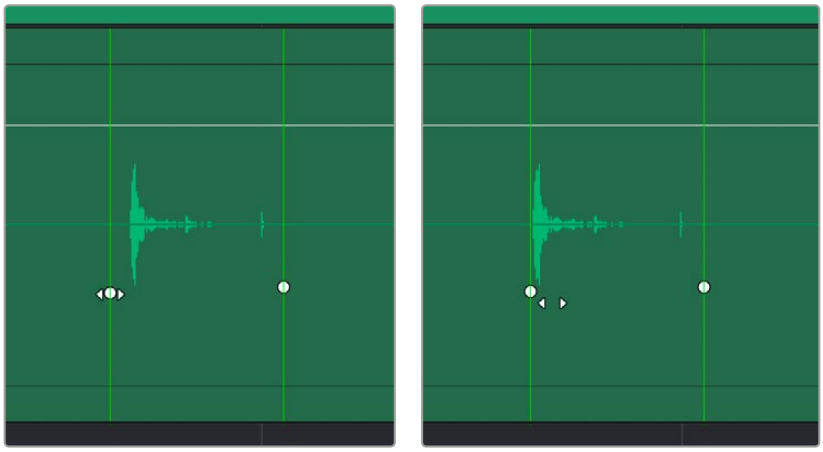
4 Dragging the speed keyframe to the left or right speeds up the audio on one side of the keyframe and slows down the audio on the other side of the keyframe, from that keyframe to the neighboring keyframes applied to that clip. Using an audio clip's waveform as your guide, you can use multiple speed keyframes to match the waveform of one performance to the waveform of another, in order to make the timing match. Or, you can adjust speed keyframes freeform to manipulate performances or sounds for creative effect.

You can also drag the beginning or end of an audio clip to retime that portion of the clip going forwards or back to the next speed keyframe that's been added.



Adjusting a series of speed keyframes to retime one performance to match another

5 If you've made some speed keyframe adjustments, but you find yourself wishing a speed keyframe you created had been placed at a different position relative to the audio waveform being adjusted, you can hold the Command key down and drag any speed keyframe to move it closer to or farther away from a part of the waveform you want it to retime. This fine-tunes the audio retiming adjustment occurring at that point in the clip.



(Left) Before Command-dragging a speed keyframe to be closer to the original beginning of the sound being retimed, (Right) After

6 When you're done, you can click the close button at the upper-left-hand corner to hide the Elastic Wave retiming controls.

To remove Elastic Wave retiming keyframes, do one of the following:

- **To remove a single speed keyframes:** Right-click on a speed keyframe and choose Remove Speed Keyframe from the contextual menu.
- **To remove all speed keyframes and eliminate the Elastic Wave retiming effect:** Right-click a clip and choose Reset Speed Curve.

NOTE: All Elastic Wave retiming adjustments you make in the Fairlight page appear in the Edit page as variable speed effects, accessible using the Retime controls. Be aware that while all Elastic Wave retiming effects can appear as Edit page retime effects, not all Edit page retime effects can appear as Elastic Wave retiming effects on the Fairlight page.

Elastic Wave Options

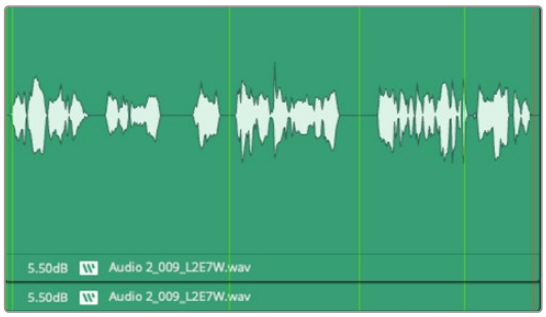
The Elastic Wave context menu has three options for processing:

- **Off:** Elastic Wave is not enabled for the clip (Default).
- **Voice:** Focused on human speech or singing. Note that this is not a good option for other material.
- **General Purpose:** Ideal for music and effects.

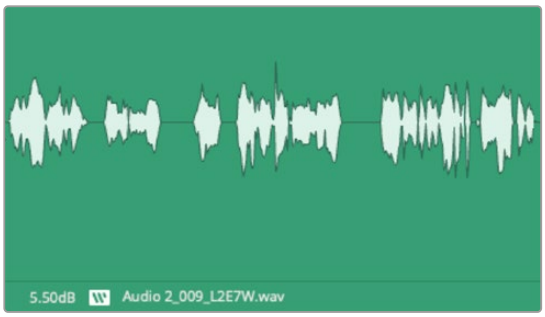
Elastic View

Elastic view shows Elastic Wave "time points," which are similar, but the not the same as, Resolve keyframes. Keyframes represent a point in time plus a value, and Elastic Wave time points represent only a point in time.

When Elastic View is enabled, time points are visible on the selected clip.



Elastic Wave time points



Elastic Wave disabled

When disabled, the time points are not visible, but the info lane still shows that Elastic Wave is enabled with the Elastic Wave icon.

Clearing Timing Points

"Timing points" are the moveable Elastic Wave control points that stretch or compress a given area of a clip. If you choose "Clear Timing Points," all selected points within a clip are cleared (deleted).

Elastic Wave can operate in the Edit window where video editors may want to re-time spoken word performances so that when the audio is re-timed, the video follows the retiming to match. However, when working in the Fairlight page, re-timing of video is disabled so that you can have separate control of the audio file.

About Audio Plugins

There is no limit to the number of single or multiple plugins when in FlexBus mode that can be applied to clips and to tracks. However there is a limit of 480 when using Fixed Bus Legacy. Plugins are accessed via each track's control strip, or via the Inspector which provides access to both clip and track plugins.

Fairlight FX

Fairlight FX are proprietary DaVinci Resolve-specific plugins that run natively on macOS, Windows, and Linux, providing high-quality audio effects with professional features to all DaVinci Resolve users on all platforms.

Most Fairlight FX plugins, including Channel Dynamics and EQ, and dynamics processors like the Multiband Compressor, Limiter, Reverb, and Ambisonics Meter, are Ambisonics native and offer multichannel processing.

VST and VSTi

VST (Virtual Studio Technology) is an audio plugin standard created by Steinberg. The VST standard allows third-party developers to create plugins for use within VST host applications or create VST host applications.

The Fairlight page supports VST effects from Mono to 7.1 and beyond. These effects can be inserted on mono channels or Link Groups, and compatible VST Ambisonic effects can be used on Ambisonic tracks or busses.

If a stereo VST effect is inserted on an LCR, LCRS, or 5.1 Link Group, the left and right channels will automatically be allocated to the left and right Link Group channels.

> DaVinci Resolve supports VST3. VST effects are available on macOS and Windows workstations, but not on Linux.

VST Effects versus VST Instruments (VSTi)

A VST effect is a type of VST plugin that is used to process audio. A VST effect might be a Reverb, Compressor, or EQ. VST Instruments are typically used to synthesize sound or play back sampled audio. VSTs have rapidly replaced hardware synthesizers and dedicated samplers due to their flexibility, repeatability, and low cost.

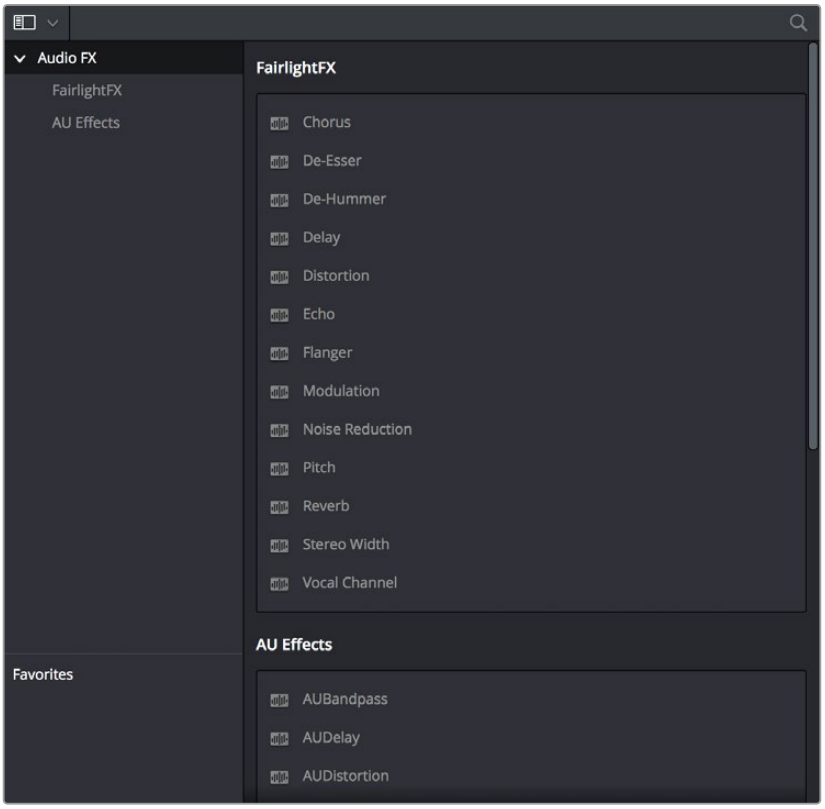
Audio Units

Audio Units is an audio plugin API created by Apple for use on macOS workstations. Like VST, Audio Units (AU) can either process audio or work as instruments.

Compatible AU Ambisonic effects are used on Ambisonic tracks or busses.

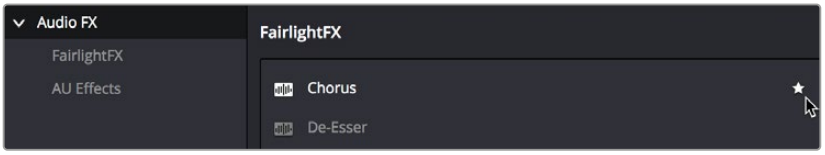
Using Audio Plugins

Fairlight FX are pre-installed with all DaVinci Resolve installations. If you install additional VST or Audio Unit effects on your workstation, they appear in the Audio FX panel of the Effects Library, organized in separate categories.



Audio plugins in the Effects Library

You can click on the far right of any effect to flag it with a star as a favorite effect. When you do so, the favorited effects appear in a separate Favorites area at the bottom of the Effects Library Bin list, and it also appears at the top of the Effects button's menu on the Mixer when you click the "plus" button.



Stars indicate a flagged favorite effect; all favorites are currently filtered

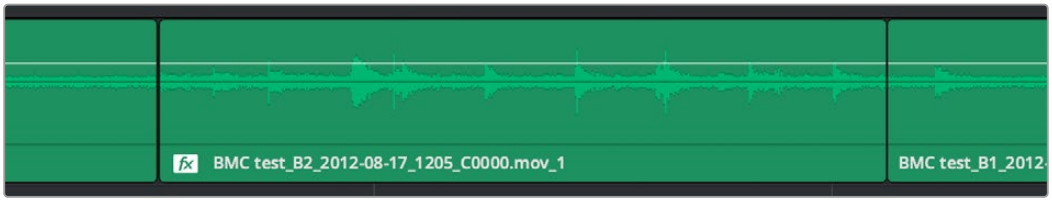
Audio plugins let you apply effects to individual audio clips or entire tracks worth of audio, to add creative qualities such as echo or reverb, or to take care of mastering issues using noise reduction, compression, or EQ.

Applying Plugins

Methods of applying audio plugins to clips on the Fairlight page:

- **To apply an audio effect to a clip:** Drag any effect from the Audio FX panel of the Effects Library onto the clip in the Timeline you want to apply it to.
- **To apply an audio effect to multiple clips:** Select all of the clips you want to apply an audio effect to, then drag any effect from the Audio FX panel of the Effects Library onto any of the selected clips.

  When you apply an audio plugin to a clip, a badge appears to the left of that clip's name bar in the Timeline to let you know there's an effect applied to it.



Timeline clips with audio plugins applied appear with a badge.

Methods of applying audio plugins to tracks on the Fairlight page:

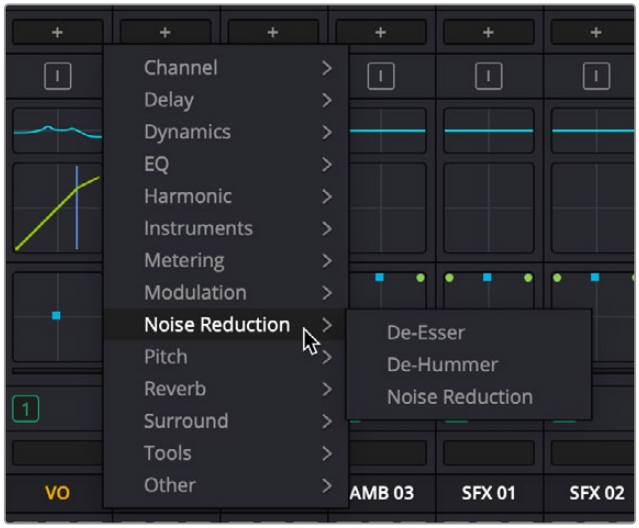
- **To apply an audio effect to an entire track in the Timeline:** Drag any effect from the Effects Library onto the track header.

Applying an audio effect to a whole track via the Timeline

- **To apply an audio effect to a track or bus in the Mixer:** Drag any effect from the Audio FX panel of the Effects Library onto the clip in the Timeline you want to apply it to.

Applying an audio effect to a whole track via drag and drop to the Mixer

- **To apply an audio effect to a track or bus using the Mixer controls:** Click the plus button in the channel strip of the track you want to apply an effect to, and then choose an effect from the dropdown menu that appears. All filters appear within categories to make them easier to find. If you've clicked the star button of any filters in the Effects Library to favorite them, these favorite filters appear at the top of the plus button's dropdown list.
- **To copy audio effects from one mixer channel to another:** Hold the Option key and click and drag the effect to the desired channel and slot to copy.
- **To reorder audio effects in the mixer:** Click and drag the audio effect to move to the desired slot position.



Applying an audio effect to a whole track via the Mixer's own controls

TIP: The categories that VST and Audio Units effects are organized into in the Mixer can be edited in the Audio Plugins panel of the DaVinci Resolve System Preferences window. All plugins on a workstation are shown in the Available Plugins list, and clicking within the Category column lets you use a dropdown menu with which to change categories.

NOTE: This does not apply to Fairlight FX plugins.

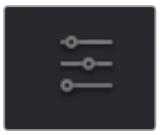
Editing Plugin Parameters

To edit a clip's audio plugins:

- Select that clip and open the Inspector. All audio plugins applied to that clip appear in the Effects tab, with that effect's controls appearing directly in the Inspector.

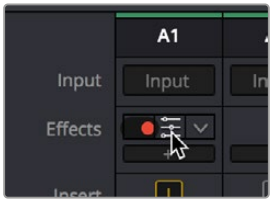
To edit a track's audio plugins, do one of the following:

- Click in the background of the Timeline header to select that track, and then open the Inspector. Click the custom UI button for that effect to open its controls.



The custom UI button for audio plugins in the Inspector

- Move the pointer over the plugin's name in the Effects area of the Mixer, and click on the custom UI button to open its controls.



The custom UI button for audio plugins in the Mixer

Nearly all Fairlight FX, VST, and Audio Unit audio plugins have a custom user interface that makes it much easier to manipulate that effect's controls. These can be opened from within DaVinci Resolve.

The custom audio effect interface for iZotope RX Voice De-noise

Working with Plugins in the Inspector

Methods of working with audio plugins in the Inspector:

- **To rearrange the order of multiple audio effects applied to a clip:** Click the move up or move down buttons in any effect's title bar, to the left of each effect's Trash Can button.
- **To disable or re-enable an effect:** Click the toggle button at the far left of each effect's title bar.
- **To remove an effect:** Click the Trash Can button.
- **To reset any effect parameter:** Click the Reset button at the far right of the parameter you want to reset.
- **To open or collapse an effect's parameters:** Double-click the title bar.
- **To open or collapse the parameters of all effects:** Hold the Option key down and double-click any effect's title bar.

Once applied to a clip or track, audio plugins can also be keyframed or automated just like volume and pan settings, to create dynamic audio effects that change over time.

Sidechaining

DaVinci Resolve supports the sidechaining of compatible Fairlight FX, AU, and VST plugins, which lets you temporarily lower the level of a target track or bus using the audible signal from a source track or bus.

This process, also known as “ducking,” is helpful when multiple tracks compete for space in a mix because they share some or all the same frequencies, such as a track or bus with dialogue and a bus with a crowd cheering at a sports event.

In the example above, the dialogue is fed to the sidechain input of a compatible dynamics plugin (i.e., a compressor or limiter) on the Mixer channel for the crowd noise. When the controls on the dynamics are set correctly, the voices on the Dialogue channel will subtly and slightly lower or attenuate the level of the crown noise, allowing the voices to be heard more prominently in the mix. When the dialogue stops, the cheering returns to its original level.

Sidechain controls

To use sidechaining

- Open the compressor or limiter on the Mixer channel with the crowd noise.
- Select the Dialogue channel in the source dropdown at the top of the plugin, to the right of the Listen button.

  This is the audio you’re using to attenuate the level of the cheering crowd.

  Using a bus as the ducking source lets you use multiple sources to trigger changes in your target track.
- Click the On button, which turns red, indicating that the Sidechain (S/C) function is active.
- Adjust the controls to taste during playback of your mix, while ensuring the effect sounds natural.

  You can experiment with this procedure using the Compressor section of the Channel Dynamics plugin or the Fairlight FX Limiter.

  For more information on sidechaining with the Channel Dynamics plugin, *see Chapter 174, “Mixing in the Fairlight Page.”*

  For more information on sidechaining with the Fairlight FX Limiter, *see Chapter 178, “Fairlight FX.”*
- Clicking the Listen button lets you hear the incoming signal if you need to confirm that the correct input signal is coming into the Limiter. This button turns yellow when active.

Applying Audio Plugins to Busses

You can apply audio plugins to Main and Sub buses just like any other track, with which to apply any audio mastering effects operations you require to individual submixes, or even to an entire main.

TIP: You can quickly assign plugins for a selected group of channel strips, or to all channel strips, by holding down the Option key (Mac) or the Alt key (Windows) for all selected tracks or Command-Option (Mac) or Control-Alt (Windows) for all mixer channel strips prior to performing the operation. These shortcuts can save a lot of time in your workflow.

Dealing With Processor Intensive Plugins

As you apply more and more plugins directly to clips in complicated mixes, you may discover you lack the processing power to play all audio tracks and effects in real time. When this happens, there are two ways you can ease the burden that audio clip effects are placing on your workstation.

Caching Audio Clips With Plugins

One quick fix is to manually enable the caching of one or more selected audio clips with audio effects applied to them to improve your project's performance. Once an audio clip is cached, all plugin effects are "baked in" and that clip's audio waveform updates to reflect the altered audio. Cached clips appear with a small badge to the right of the FX badge in the name bar of the clip.

A cache badge lets you know this audio clip has cached effects

This is a non-destructive operation that has no lasting effect on the source media of cached clips. You can still alter a cached clip's plugin parameters whenever you want. Opening the graphical controls of a cached clip temporarily suspends audio caching, and when you're finished, the clip is automatically re-cached and its waveform is updated to reflect the change so long as Cache Audio Effects remains enabled.

To cache audio effects for one or more selected clips:

- Right-click an audio clip with a plugin applied and choose Cache Audio Effects to enable audio effect caching for that clip. If you right-click one of multiple selected clips, you'll enable Cache Audio Effects for all selected clips at once. Once enabled, that clip will be continue to be cached (and re-cached if you change the plugin's parameters) until you manually disable audio caching.

To disable audio caching for one or more selected clips:

- Right-click an audio clip that's been cached and choose Cache Audio Effects to disable audio effect caching for that clip.

Exporting Audio Clips With Plugins

Another way of easing the burden of audio clip effects on your system is to export the effected clip to another layer. This creates a new piece of audio media with the effect "baked in," which is written to the directory location specified by the "Save clips to" field of the Capture and Playback panel of the Project Settings.

To bounce one or more selected audio clips with effects to another layer:

- Right-click an audio clip with a plugin applied and choose Export Audio Files. If you right-click one of multiple selected clips, you'll have options for what you would like exported for each selected clip all at once.

  Exported clips no longer have editable effects, but you can always choose View > Show Audio Track Layers to see the original underlying clip that still has the original plugin effect applied, and you can unmute it, move it back up to the top, edit the effect, and export another version of the clip, which appears as the topmost layer.

For more information on exporting clips to files, *see Chapter 172, "Editing Basics in the Fairlight Page."*

Chapter 178

Fairlight FX

Fairlight FX are DaVinci Resolve-specific audio plugins that run natively on macOS, Windows, and Linux and provide high-quality audio effects with professional features to all DaVinci Resolve users.

These plugins are available on the Edit and the Fairlight pages and offer various options for repairing faulty audio, creating effects, and simulating spaces.

On the Fairlight page, they're categorized as either Track FX or Audio Effects based on their position in the Fairlight Mixer's signal path.

For more information on For more information on the Fairlight Mixer's signal path, *see Chapter 174, "Mixing in the Fairlight Page."* This chapter explains what they do and how to use them.

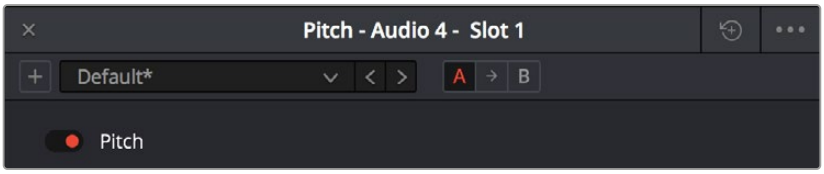
Common Controls For All Fairlight FX

Before going into the specific controls of each Fairlight FX plugin, there are some common controls that all plugins share, found at the top of the custom GUI window for each plugin.



Common controls for all Fairlight FX

- **Presets:** A cluster of controls that let you recall and save presets specific to each plugin.

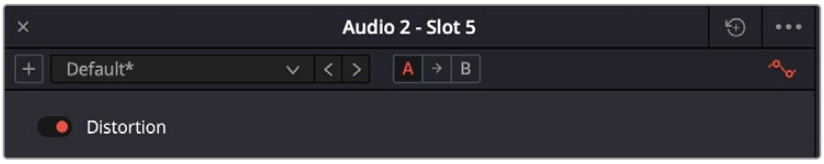
  Add Preset button: Click this button to save the current settings of the Fairlight FX you're using. A dialog box lets you enter a Preset name and click OK.

  Preset dropdown menu: All presets for the currently open plugin appear in this menu.

  Previous/Next preset buttons: These buttons let you browse presets one by one, going up and down the list as you evaluate their effects.

- **A/B Comparison:** A set of buttons that lets you compare two differently adjusted versions of the same plugin. The A and B buttons let you create two sets of adjustments for that plugin, and toggle back and forth to hear which one you like better. The arrow button lets you copy the adjustments from one of these buttons to the other, to save the version you like best while experimenting further.
- **Reset:** A single reset control brings all parameters in the current plugin to their default settings.

  When the Automation is turned on, an automation button appears at the top right of each of the plugins. Automatable parameters for that effect are available in the Plugin dropdown menu for that track.



Automation activated and available to the Fairlight FX

NOTE: Although Default is the preset when initially opened, many of the plugins, have presets already created. Reverb, for instance, has Cathedral, Concert Hall, and Studio presets built in.

These can be excellent starting points to change, rename, and save for your specific needs. These new presets will also be available in the Preset dropdown menu.

TIP: Fairlight FX support "granular" control adjustments by holding down the Option or Shift key while clicking in and dragging left or right within the numerical value fields for virtual sliders in a Fairlight FX plugin or the Inspector.

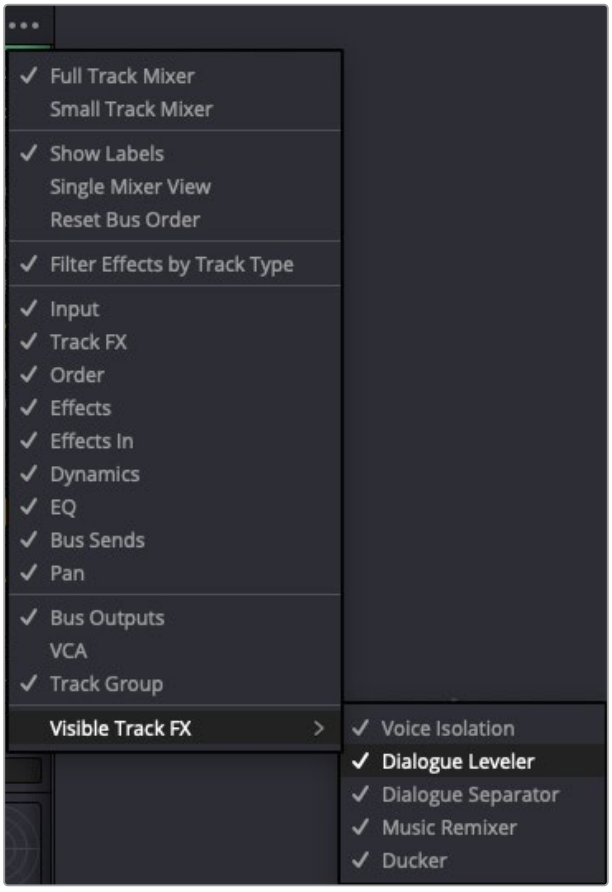
Track FX

These built-in Fairlight FX plugins are accessed via the Track FX section of Audio Track channel strips or in the Inspector. If the Track FX section doesn't appear in the Mixer, click the three dots in the upper-right corner of the Mixer and select Track FX.

The available plugins in this category are: Voice Isolation, Dialogue Leveler, Dialogue Separator, Music Remixer, and Ducker.

Each plugin occupies a fixed, dedicated insert point in the Track FX section, with the Voice Isolation and Dialogue Leveler visible by default. To reveal the other Track FX plugins, click the three dots in the upper-right corner of the Mixer and select each plugin from the "Visible Track FX" submenu at the bottom.

TIP: Track effects can be applied to stereo-linked groups (stereo-linked tracks).



The Mixer menu

Dialogue Leveler

The Dialogue Leveler analyzes source material to detect dialogue and then "rides down" louder areas, "lifts up" softer areas, and lowers background sounds that are not dialogue.

It works without the typical "pumping" or other unwanted side effects of dynamics processors (compression/limiting) to produce results like those achieved through detailed, manual clip gain adjustments or "riding" the track with fader automation.

The Dialogue Leveler can often “fix and mix” a recording made with a single boom mic, where one character is closer than another or turns away from the mic and levels it out so that the original relative dynamics are preserved while increasing intelligibility and average level.

The Dialogue Leveler plugin

Although Dialogue Leveler can be used on an audio track in real time, it cannot be used on live audio input. It can be used on any mono, stereo, or dual-mono audio track, but it isn’t supported on tracks with more than two channels.

Dialogue Leveler controls:

- **Dialogue Leveler:** Enables or disables the plugin.
- **Waveform Processing display:** This shows a scrolling waveform and a gray line indicating Dialogue Leveler processing. However, this display is not available when using the Dialogue Leveler found in the Inspector to process audio clips on the timeline.
- **Preset Menu:** This menu provides the following options:

  Allow wider dynamics: This is the default and is best for audio with a wider-ranging dynamic from loud-to-soft, and where the clip levels are medium to high.

  More lift for low levels: Select this option if the source has more low-level dialogue that you want to boost.

  Lift soft whispery sources: Select this option if the source has whispered dialogue and background noise.

  Optimize moderate levels: Select this option if the source is at medium levels throughout.

- **Reduce Loud Dialogue:** When enabled, louder dialogue is ridden downward when it peaks, acting like a “perfect limiter” where you don’t have to adjust the threshold or time parameters. Due to the “near real-time” functionality, analysis occurs prior to audible playback for optimal results.
- **Lift Soft Dialogue:** This setting finds and lifts low-level dialogue, evening-out material that is quieter while more variable in level. Because the process is dialogue-focused, it doesn’t tend to raise background sounds unless they’re audible at the same time as the dialogue.

  The Lift Soft Dialogue option is often the most useful of the three options, as it makes quieter lines of dialogue louder and naturally smooth without boosting background noise.

- **Background Reduction:** This option gently removes background noise based on the internal preset selected in the Preset menu.
- **Output Gain:** You can use this control to adjust the output level by clicking and dragging it or entering a value in the numeric field. The range of the Output Gain control of 0.0 to +6.0 dB.

TIP: Before using the Dialogue Leveler on a track, it can be useful to set an optimum baseline level for use with the default “Allow wider dynamics” preset by normalizing the audio.

For more information on normalizing audio, *see Chapter 173, “The Fairlight Inspector.”*

Dialogue Separator (Studio Version Only)

Dialogue Separator uses DaVinci Neural Engine AI to give you individual control over the level of dialogue, background sounds, and the reverberant field or ambient room sound (“ambience”).

The Dialogue Separator plugin

The Dialogue Separator is useful when, for example, a source file has a great roomy sound, but there’s music or crowd noise in the background. In this instance, you can rebalance the audio to reduce the background sounds or adjust the room sound to make the dialogue more intelligible.

Another use case would be when someone moves toward the camera in a roomy environment while speaking. You could use automation to rebalance the audio so that the ambient room sound gradually becomes “drier” as they get closer, without affecting the background.

Dialogue Separator is currently a mono-only plugin. If your source is stereo, you’ll need to split it into dual-mono and process both mono tracks separately.

Ducker

This plugin lets you use the audible signal from a track or multiple tracks to lower the level of another.

Although it can be used in many creative ways, a common use of “ducking” is automatically lowering a music or sound effects bed so that dialogue or a VO track can be heard more prominently in a mix.

This is achieved without compressing the incoming signals. When set up correctly in the Ducker interface or via the Audio tab in the Inspector, your audio tracks can practically “mix themselves.”

In a simple use case, the Ducker uses level changes of a single incoming dialogue or VO track to decrease the volume of the sound effects bed of a noisy freeway.

In a more complex situation, such as a scene where three characters are conversing next to the same noisy freeway, a single Ducker plugin can use the level changes of each dialogue track to attenuate the traffic noise.

With only one input source (Dialogue 1), the Ducker would only be effective when the first character speaks. However, this new feature lets you add the other two dialogue tracks (Dialogue 2 and Dialogue 3) as input sources for attenuating the traffic noise.

The Ducker plugin

Using the Ducker

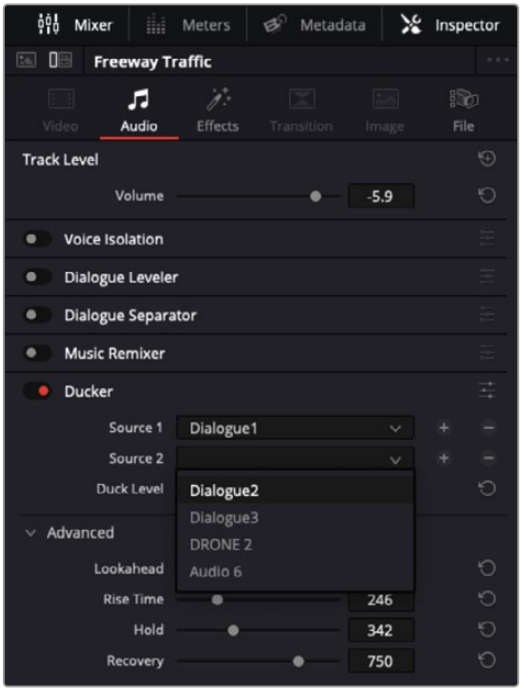
Continuing with the use cases mentioned above:

1. Choose the target track that you want to attenuate (the Freeway Traffic track), and open the Ducker.
2. Click the Source dropdown and select Dialogue 1 as the input source.
    - To use additional input sources, Command-click the other track names; in this example, Dialogue2 and Dialogue3.
    - Play a bit of your sequence, and adjust the duck level and other controls to taste.

Adding Input Sources via the Inspector

If you prefer working within the Inspector:

1. Select the Freeway Traffic track, ensure the Ducker is switched on, and open the Inspector's Audio tab.
2. Click the plus sign to the right of the Source 1 dropdown containing Dialogue 1 to create a dropdown menu for Source 2, then choose Dialogue2 from the list.
3. Click the plus sign to the right of the Source 2 dropdown to create a dropdown menu for Source 3, then choose Dialogue3 from the list.



Adding Ducker input sources in the Inspector

Ducker Controls

- **Duck Amount:** This control determines level attenuation on the target track in dB with a default value of 2.7 dB. Most of the time, a value between 2.0 dB and 5.0 dB works the best.
- **Lookahead:** Adjusts the amount of lookahead time in milliseconds, with a default value of 15ms. Lookahead allows the Ducker to start attenuating the destination track before the source track is audible.

  The larger the value, the more the Ducker will "pre-anticipate" the source track. If you want the Ducker to start lowering the sound before a line of dialogue or VO begins, you can experiment with higher values, but the default will usually produce good results.
- **Rise Time:** This determines how many milliseconds it takes for the Ducker to reach the amount of reduction specified by the Duck Amount. The default value is 10 milliseconds, which should work for most situations. Longer Rise Times may be useful with higher Duck Amount values and longer gaps in the source track.
- **Hold:** This parameter determines how long the target signal will be attenuated. The default is 150ms.
- **Recovery Time:** This value indicates how quickly the target signal will return to its previous level after attenuation. The default time value is 750ms, but setting the correct Recovery time is crucial to a natural-sounding ducking process, so you should try different values to find the best results.

Ducker Graph Display

This area shows a gray line representing the incoming signal against the action of the Ducker, shown in yellow. Dips in the yellow line signify attenuation of the target track based on the Duck Amount in combination with the other parameters.

Music Remixer (Studio Version Only)

This DaVinci Neural Engine AI-based plugin splits music into individual stems: Vocals, Drums, Bass, Guitar, and “Other” (“everything else”), letting you creatively rebalance or remix the track.

You can use the level controls to adjust the volume of each stem and the Mute buttons to remove or bring them back into your mix. For example, you may want to remove or lower a vocal because it clashes with a featured piece of dialogue.

The Music Remixer plugin

Voice Isolation (Studio Version Only)

Voice Isolation uses an AI model trained for any type of human voice, male or female, young or old, which lets you completely remove loud, undesirable sounds from existing voice recordings with incredible results.

The Voice Isolation plugin

You can get rid of all kinds of background noise, from air conditioners or fans to jackhammers, restaurant background noise, music playing during a featured piece of dialogue, and more.

The Amount control adjusts the mix between the original source and the isolated voice. When set to 50, the mix is roughly equal. Values between 70 and 80 work well for natural results while strongly isolating the source.

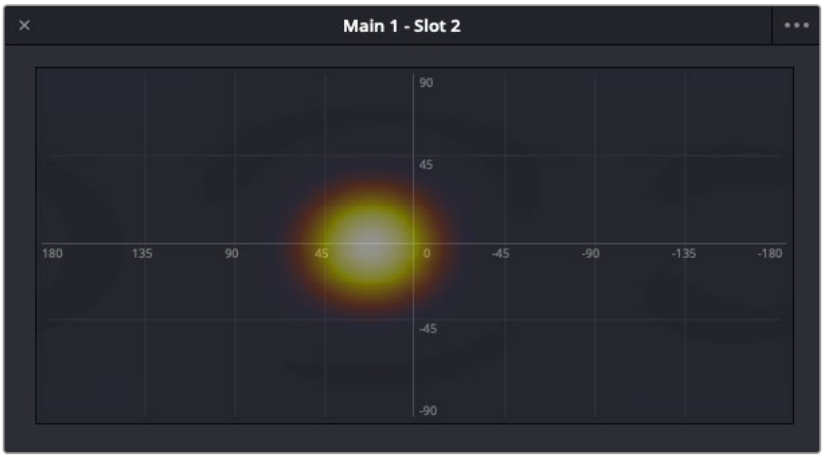
Although Voice Isolation can be used on an audio track in real time, it cannot be used on live audio input. It can be used on any mono, stereo, or dual-mono audio track, but it isn’t supported on tracks with more than two channels.

Insert Effects

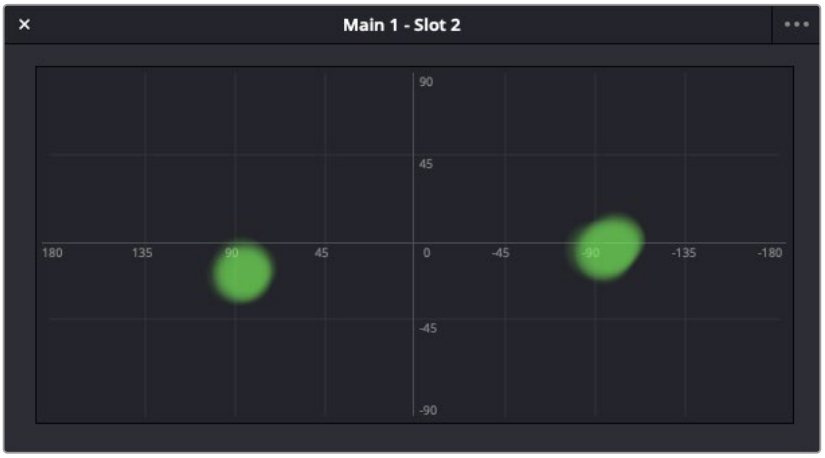
Ambisonics Meter

This Fairlight FX plugin can be inserted on an Ambisonics track or bus to present a graphic display of your Ambisonic sound field. Clicking the three dots in the upper right opens an options menu where you can choose either “power” (Power Map), or “Sonar” style map as the metering method.

Both meters convey the intensity of the sound and its current location in the Viewer.



Ambisonics meter - Power Map view



Ambisonics meter - Sonar view

Chorus

An effects plugin. A classic Chorus effect, used to layer voices or sounds against modulated versions of themselves to add harmonic interest in different ways.

An animated graph shows the results of adjusting the Modulation parameters of this plugin, giving you a visualization of the kind of warble or tremolo that will be added to the signal as you make adjustments.

The Chorus Fairlight FX

Chorus has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Input Format:** (Only visible when Chorus is inserted on a multi-channel track.) Lets you choose how multiple channels are input to the Chorus. Stereo sets separate Left and Right channels. Mono sums Left and Right to both channels. Left inputs the Left channel only, and Right inputs the Right channel only.
- **Delay:** The amount of delay between the original sound and the Chorus effect.

  Delay Time: Length of the Chorus delay lines.

  Separation: Time separation of the delay voices.

  Expansion: Sets L/R length differences, phase offset of modulators.

- **Modulation:** These controls adjust the low frequency oscillator (LFO) that drives the tremolo of the chorus effect in different ways.

  Waveform: Specifies the shape of the LFO that modulates the rate of the Chorus, affecting the timing of the oscillations. There are six options for the oscillator for you to choose from:

  Sine (Smooth oscillations)

  Triangle (Sudden oscillations)

  Saw1 (Jerky oscillations)

  Saw2 (Jerky oscillations)

Square (Hard stops between oscillations)

Random (Randomly variable oscillations)

Frequency: Rate of LFO controlling the Chorus. Lower values generate a warble, higher values create a tremolo.

Pitch: Amount of frequency modulation, which affects the pitch of the Chorus.

Level: Depth of level modulation. Affects the “length” of the segment of Chorus that’s added to the sound. Low values add only the very beginning of the Chorus effect, high values add more fully developed Chorus warble or tremolo.

- **Feedback:** A signal fed back to the Chorus Delay Line

  Amount (%): The percentage of signal fed back to the Chorus Delay Line. Values can be positive or negative, the default is 0 (no effect). Increasing this parameter adds more of the Chorus effect to the signal, lowering this parameter adds more of the inverted Chorus effect to the signal. At values closer to 0, only a faint bit of Chorus can be heard in the audio, but at values farther away from 0 (maxing at +/- 99), a gradually pronounced Chorus becomes audible.

  Blend (%): Amount of feedback which bleeds into the opposite channel (Stereo mode only).

- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of “dry” or original signal to “wet” or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

De-Esser

A repair plugin specific to dialog. The De-Esser is a specialized filter that’s designed to reduce excessive sibilance, such as hissing “s” sounds or sharp “ts” sounds, in dialogue or vocals.

A graph shows you which part of the signal the controls are set up to adjust, while reduction and output meters let you see which part of the signal is affected and what level is being output.

The De-Esser Fairlight FX

The De-Esser has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Listen to Ess Only:** This checkbox at the top right lets you listen only to the ess that is being removed. This is very useful to determine if too much signal is being removed or if more ess attenuation can be applied.
- **Frequency Range:** Two controls let you target the frequency of the “s” sound for a particular speaker.

  Target Frequency: A knob that lets you target the frequency of the offending sibilance. Sibilant sounds are usually found in the range of 5 - 8kHz.

  Range: switches the operational mode of the De-Esser. Three choices (from top to bottom) let you switch among Narrow Band, Wide Band, and All High Frequency which processes all audio above the source frequency.
- **Amount:** Adjusts the amount de-essing that’s applied.
- **Reaction Time:** Adjusts how suddenly de-essing is applied. There are three choices.

  Slow: Equivalent to a slow attack.

  Medium: Equivalent to a medium attack.

  Fast: Equivalent to a fast attack.

De-Hummer

A repair plugin with general applications to any recording. Eliminates hum noise that often stems from electrical interference with audio equipment due to improper cabling or grounding. Typically 50 or 60 cycle hum is a harmonic noise, consisting of a fundamental frequency and subsequent partial harmonics starting at twice this fundamental frequency.

A graph lets you see the frequency and harmonics being targeted as you adjust this plugin’s controls.

The De-Hummer Fairlight FX

De-Hummer has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Listen to Hum only:** This checkbox at the top right lets you listen only to the hum that is being removed. This is very useful to determine if too much signal is being removed or if more hum attenuation can be applied.
- **Frequency:** Target source fundamental frequency. A knob lets you make a variable frequency selection, while radio buttons let you select common frequencies that correspond to 50Hz/60Hz electrical mains that are the typical culprits for causing hum.
- **Amount:** Adjusts how much De-Hum extraction you want to apply.
- **Slope:** Adjusts the ratio of fundamental frequency to partial harmonics, the adjustment of which lets makes it possible for various kinds of hum to be targeted. For example, a value of 0 biases hum extraction towards the fundamental frequency, while a value of 0.5 gives equal extraction of all harmonics (up to 4), and finally a value of 1.0 targets the higher frequency partials.

Delay

An effects plugin. A general purpose stereo delay effect, suitable for tasks varying from track doubling, to early reflection generation, through simple harmonic enhancement. Processes in stereo or mono, depending on the track it's applied to.

A graph shows the timing and intensity of the echoes generated by this plugin on each channel, and an Output meter displays the output level of the resulting signal.

The Delay Fairlight FX

Delay has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Input Format:** (Only visible when Delay is inserted on a multi-channel track.) Lets you choose how multiple channels are input to the delay. Stereo sets separate Left and Right channels. Mono sums Left and Right to both channels. Left inputs the Left channel only, and Right inputs the Right channel only.

- **Filters:** Alters the proportion of frequencies that are included in the delay effect. When the Delay plugin is inserted on a Mono Channel, the Left and Right sections are replaced with a single “Delay” section.

  Low Cut (Hz): A global High Pass filter.

  High Cut (Hz): A global Low Pass filter.

- **Delay:** Adjusts the timing of the delay.

  Left/Right Delay (ms): Delay time of each channel.

  Left/Right Feedback (%): Feedback % of the Left or Right channel back to itself. A negative value equates to % of feedback with a phase reverse from the original signal.

- **Feedback:** Controls for adjusting the amount of bleed between channels.

  High Ratio: Adjusts the frequency of a damping filter for the feedback signal.

  Stereo Blend: Adjusts the proportion of signal from Left and Right channel feedback which feeds into the opposite channel. When the Delay plugin is inserted on a Mono channel, Stereo Blend control does not appear.

- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of “dry” or original signal to “wet” or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

Dialogue Processor

The Dialogue Processor chains together six different common audio processing operations inside of a single plugin, each tuned to the specific needs of adjustments to improve recorded dialog. The specialized De-Rumble, De-Pop, De-Ess, Comp(ressor), Expander, and Excite controls each have a streamlined set of controls tailored to the specific types of common adjustments that may be required for a great sounding dialogue track.

The Dialogue Processor plugin

- **De-Rumble:** The de-rumble filter is a high pass filter that allows you to remove subsonic rumble (subharmonic low frequencies) in your vocal microphone signal. A safe value to use for most condenser microphones is 40 or 50Hz. Using higher values can start to remove lower frequencies in the source signal, which can be a useful creative effect at times.

  Frequency: Sets the high-pass filter to frequencies between 40Hz to 235Hz.

- **De-Pop:** Controls the center frequency for a specialized filter for removal of vocal "popping" sounds, or plosives, that can occur when someone speaks close to a microphone capsule on-axis.

  Frequency: Sets the filter to frequencies between 50Hz to 200Hz.

  Amount: Sets the amount of the filter effect on the signal with lower values effecting less and higher values effecting more. A meter next to the amount knob shows how the signal is being effected.

- **De-Ess:** Sets the center point of a specialized bandpass filter for removal of vocal "Esses," which can be overly present due to sibilance. De-essing allows you to raise average level and brighten a vocal source without it sounding harsh, as our ears are very sensitive to overly present sibilance. The best frequency range for male and female voices tends to be between 6 and 7 kHz.

  Frequency: Sets the filter to frequencies between 700Hz to 9000Hz.

  Amount: Sets the amount of the filter effect on the signal with lower values effecting less and higher values effecting more. A meter next to the amount knob shows how the signal is being effected.

- **Compressor:** Used to compress a signal's dynamic range by reducing differences in level between the loudest and quietest parts of the input signal. Compression can be used to raise the signal's overall level, boosting it without clipping and thus increasing perceived loudness. Compression is often used to give voices more presence within a mix and to smooth out changes in the levels of tracks that may have too much dynamic range for its context.

  Threshold (dB): Sets the level at which the signal will start to be effected from –40dB to –8dB.

  Amount: Sets the amount of the compression on the signal with lower values effecting less and higher values effecting more. A meter next to the amount knob shows how the signal is being effected.

  Fast/Slow: Determines the speed at which the effect is applied, fast or slow.

- **Expander:** Emphasizes differences in volume by lowering the level of soft parts of the signal relative to the level of louder parts and can be used to minimize noise while increasing the dynamic range of a signal.

  Threshold (dB): Sets the level at which the signal will start to be effected from –40dB to –8dB.

  Range: Amount of decrease in signal level in dB, as expansion lowers the softer parts of the signal.

  Fast/Slow: Determines the speed at which the effect is applied, fast or slow.

- **Excite:** Synthesizes additional high frequency content in a source signal, using various techniques. Used subtly, it can add more presence to sounds that may be overly dull without having to use EQ.

  Amount: Sets the amount of the exciter on the signal with lower values effecting less and higher values effecting more. A meter next to the amount knob shows how the signal is being effected.

  Female/Male: Tailors the exciter's response to be optimized for a male or female voice.

Dialogue Leveler

The Dialogue Leveler analyzes source material to detect dialogue, and then “ride down” louder areas, “lift up” softer areas, and lower background sounds that are not dialogue. It works without typical dynamics processor “pumping” (compression/limiting) or other obvious side effects, and produces results similar to detailed manual clip gain adjustments or by carefully “riding” the track with fader automation. Dialogue Leveler can often “fix and mix” a recording with a single boom mic where one character is closer than another or turns away from the mic at times, and level it out so that the original relative dynamics are preserved while increasing intelligibility and average level.

The Dialogue Leveler plugin

Dialogue Leveler can be used on track audio in real time but not on live audio input. Dialogue Leveler can be used on any mono or stereo (or multi-mono) audio track, but it is not supported on greater-than-stereo tracks.

Dialogue Leveler has the following controls:

- **Dialogue Leveler:** Enables or disables Dialogue Leveler processing.
- **Waveform Processing display:** Shows a scrolling waveform display and indicates Dialogue Leveler processing with a gray line. However, note that the display does not appear in the version of Dialogue Leveler for clip-based processing.
- **Preset Menu:** The preset menu provides the following options:

  Allow wider dynamics: This is the default, and is best for sources with wider ranging dynamic levels from loud-to-soft, and where the clip levels are medium to high.

  More lift for low levels: Select this option if the source has more low level dialogue that you want to boost.

  Lift soft whispery sources: Select this option if the source has whispered dialogue and background noise.

  Optimize moderate levels: Select this option if the source is at medium levels throughout.

- **Reduce Loud Dialogue:** When enabled, louder dialogue is ridden downward on peaks and acts somewhat like a “perfect limiter” where you don’t have to adjust threshold or time constants. Due to the “near real time” aspect, analysis occurs prior to audible playback for optimal results.
- **Lift Soft Dialogue:** When enabled, finds low level dialogue and lifts and evens out material that is more variable in level and softer, but because the process is dialogue focused, it doesn’t tend to raise background sounds (unless they are happening at the same time as the dialogue itself).

More often than not, the Lift Soft Dialogue option is the most useful of the three options, as it makes less audible lines of dialogue more audible and naturally smooth, while not boosting background noise.

- **Background Reduction:** When enabled, reduces background sounds by focusing on dialogue and gently removing them based on the internal presets (Preset menu).
- **Output Gain:** Adjust the Output Gain by clicking and dragging on the Output Gain control or by entering a value in the numeric field (Output Gain control in dB with 0 to +6 dB range with .1dB resolution).

Distortion

An effects plugin. Creates audio distortion that's useful for sound design and effects, ranging from simple harmonic distortion simulating an audio signal going through primitive or faulty electronics (such as bad speakers, old telephones, or obsolete recording technologies), all the way to mimicking an overdriven signal experiencing different intensities of hard clipping (think someone yelling through a cheap bullhorn, megaphone, or PA system). This plugin includes soft tube emulation in the output stage.

An animated graph shows the results of adjusting the Distortion parameters of this plugin, giving you a visualization of the kind of harmonic distortion, waveshaping, and clipping that will be modifying the signal as you make adjustments. Input and Output meters let you see how the levels are being affected.

The Distortion Fairlight FX

Distortion has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Filters:** Two filters let you simulate devices reproducing limited frequency ranges.

  LF Cut: Low frequency distortion shaping.

  HF Cut: High frequency distortion shaping.

- **Distortion:** Three sets of controls let you create the type and intensity of distortion you want.

  Mode buttons: Switch the operational mode of distortion. The one to the left, Distortion, creates harmonic distortion. The button to the right, Destroy, is a more extreme polynomial waveshaper.

  Distortion: Adjusts the amount of distortion that's applied to the signal. Higher values distort more.

  Ceiling: Adjusts the level of input signal that triggers clipping.

- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of "dry" or original signal to "wet" or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

  Auto Level button: Applies automatic compensation for gain added to the signal due to the distortion being applied. Having this button turned on prevents the signal from becoming dramatically and unexpectedly increased, while turning it off frees you to do what you want, if what you want is to hear a lot of distortion.

Echo

An effects plugin. A classic Echo effect, simulating the reflection of sounds that occur with a delay after the direct sound is heard. Processes in stereo or mono, depending on the track it's applied to.

A graph shows the timing and intensity of the echoes generated by this plugin on each channel, and an Output meter displays the output level of the resulting signal.

The stereo Echo Fairlight FX

Echo has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Input Format:** (Only visible when Echo is inserted on a multi-channel track.) Lets you choose how multiple channels are input to the echo. Stereo sets separate Left and Right channels. Mono sums Left and Right to both channels. Left inputs the Left channel only, and Right inputs the Right channel only.

- **Filter:** Alters the proportion of frequencies that are included in the delay effect. When the Delay plugin is inserted on a Mono Channel, the Left and Right sections are replaced with a single “Delay” section.

  Low Cut (Hz): A global High Pass filter.

  High Cut (Hz): A global Low Pass filter.

  Feedback: Adjusts the frequency of a damping filter for the feedback signal.

- **Left Channel:** Parameters that independently affect delay on the Left Channel. When the Echo plugin is inserted on a Mono Channel, the Left Channel and Right Channel sections are replaced with a single “Echo” section with only the Delay Time, Feedback Delay, and Feedback controls.

  Delay Time: Global Delay time for the Left Channel.

  Feedback Delay: Echo Delay time for the Left Channel.

  Feedback: Feedback percentage of the Left channel back to itself.

  L > R Feedback: Percentage of Left feedback signal which feeds back to Right Channel.

- **Right Channel:** Parameters that independently affect delay on the Right Channel.

  Delay Time: Global Delay time for the Right Channel.

  Feedback Delay: Echo Delay time for the Right Channel.

  Feedback: Feedback percentage of the Right channel back to itself.

  R > L Feedback: Percentage of Right feedback signal which feeds back to Left Channel.

- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of “dry” or original signal to “wet” or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

Flanger

An effect plugin, giving that unmistakable Flanger sound dating from the days of dual tape machines with a slight delay added to one in periodic intervals causing flanging as they got back in sync with one another. Typically used to add a sort of warbling harmonic interest to a signal, in a wide variety of ways.

An animated graph shows the results of adjusting the Modulation parameters of this plugin, giving you a visualization of the kind of warble that will be added to the signal as you make adjustments.

The Flanger Fairlight FX

The Flanger has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Input mode:** (Only visible when the Flanger is inserted on a multi-channel track.) Lets you choose how multiple channels are input to the Flanger. Stereo sets separate Left and Right channels. Mono sums Left and Right to both channels. Left inputs the Left channel only, and Right inputs the Right channel only.
- **Modulation:** A low frequency oscillator (LFO) used to drive the Flanger effect.

  Waveform (Hz): Specifies the shape of the LFO that modulates the rate of the Flanger. The three choices are Sine (a smooth change in rate), Triangle (a jerky change in rate), and Sawtooth (an abrupt change in rage). Affects the timing of the warble that is added to the sound.

  Rate: Speed of the LFO, affects the speed of the warble that is added to the sound. Low rate values create a slow warble, while high rate values create more of a buzz.

  Depth: Affects the "length" of the warble that is added to the sound. Low values add only the very beginning of a warble, high values add more fully developed warble.
- **Width:** Consists of a single parameter, Expansion, which sets Left/Right channel length differences, along with the phase offset of modulators.
- **Feedback:** These controls determine, in large part, how extreme the Flanging effect will be.

  Amount (%): The percentage of signal fed back to the Delay Line. Values can be positive or negative, the default is 0 (no effect). Increasing this parameter adds more of the Flange effect to the signal, lowering this parameter adds more of the inverted Flange effect to the signal. At values closer to 0, only a faint phase shift can be heard in the audio, but at values farther away from 0 (maxing at +/- 99), a gradually increasing warble becomes audible. The type of warble depends on the Modulation controls.

  High Ratio: Determines the attenuation of the echo over time.
- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of "dry" or original signal to "wet" or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

Foley Sampler

The Foley Sampler is a built-in sampler that makes it easy to add sound effects that you want to play using a keyboard, pad, or other MIDI performance device connected to your computer, to add timed sound effects to sync with onscreen visuals. This plugin has been designed to simplify the process of recording performed audio cues on the current track to which the sampler has been added.

Setting Up the Foley Sampler

Using the Foley Sampler to record samples played with a MIDI controller is easy.

1. Create an audio track for your sound effects or instrument recording.
2. Drag the Foley Sampler onto the track header to assign it to that track. The Foley Sampler window automatically appears. The Fairlight page knows this is an instrument with no inputs to the plugin, so this effect is automatically patched to that track's input, ready for recording.
3. If you have a MIDI controller of some kind connected to your computer and properly configured, it will appear in the MIDI dropdown menu at the upper-right corner of the Foley Sampler window (next to the Keyboard button). Choose your device from this menu, and the Keyboard button will highlight to show it's enabled.

At this point, the Foley Sampler is ready to be used, but by default it has no samples loaded to play. The next step is to add sound effects.

Adding Sound Effects

You can add prerecorded sound effects or instruments to the Foley Sampler in the following ways:

- Drag and drop an audio file in a supported format from the file system onto the Foley Sampler window
- Drag and drop a sound effect from the Sound Library onto the Foley Sampler window
- Click the Foley Sampler window's Option menu and input sounds from your attached drives.

Once you've loaded a sound effect of some kind, it's automatically mapped to the top four keys of your instrument, starting at C2. Pressing a key or pad of your controller will play that sound.

To see the sound's waveform, click the Sample button at the top of the Sound panel. In this example, there are a series of continuous footsteps recorded in a row that we can use.

A footsteps recording loaded into the Foley Sampler

Splitting Sound Effects

It's common to use pre-recorded library sound effects that consist of a series of recorded footsteps, cloth rustles, punches, or other "foleyed" sound recordings, in order to play variations of a specific kind of repetitive sound effect in sync to action that's happening on screen. The Foley Sampler lets you do this easily.

1 After you've loaded a sound effect, click the Foley Sampler window's Option menu and choose Split Sample to automatically split the current sample into slices based on an analysis of its noise floor, and assign each slice to a set of keys or pads on your selected MIDI device. Continuing with the previous example, each footstep has been split and assigned to a different key.

2 To adjust the timing of each slice of the sound effect that's been split apart, you can click on the assignment text above the keyboard at the bottom of the window to see that slice in the Sample view.

3 You can adjust the Range Start and Range End parameters to encompass as much or as little of that slice as you want to play back.

4 If you want a sample to loop if a note is held down, you can enable the Loop button, and then adjust the Loop Start and Loop End parameters to choose how much of each slice will loop.

5 To delete slices that aren't useful, you can select a slice you don't like and press Shift-Delete to clear that slice from the virtual keyboard.

A single slice of the footsteps recording after being split in the Foley Sampler, with the range of the effect adjusted

Assigning Sound Effects Manually

When you first load sound effects into the Foley Sampler, they're automatically assigned to a series of notes. Each additional sound effect that you load is automatically assigned to the next series of notes to the right. Once all notes are occupied, additional sound effects will shuffle all previous assignments to the left.

You also have the option of manually assigning sound effects that you load. This is useful when you want to manually load a variety of different sound effects all at once (such as a combination of punch sounds, human grunts, and cloth rustles to use in a fight scene), and assign them to particular notes of your choosing.

1 Load a sound effect you want to map.

2 Click the Mapping button to remap the range of notes it corresponds to.

3 Use the Low and High parameters to select a range of notes for the selected sound.

4 You also have the option of tuning the pitch of specific sound effects, if necessary.

The Mapping controls used to assign a sound to a particular set of notes

Adjusting Sound Effects

If you want to customize a sample or slice further, you can select it above the virtual keyboard and use the controls on the Level panel to control the dynamics of audio playback, or you can use the controls on the Filter panel to EQ the sound.

TIP: If a sample or slice is set to loop, you can press the Control key and click a key on the virtual keyboard to initiate looping, so you can hear these adjustments as you're making them.

Playing and Recording Sound Effects

Once you've set up the Foley Sampler with sound effects you can play from a MIDI controller, recording those sound effects is simple.

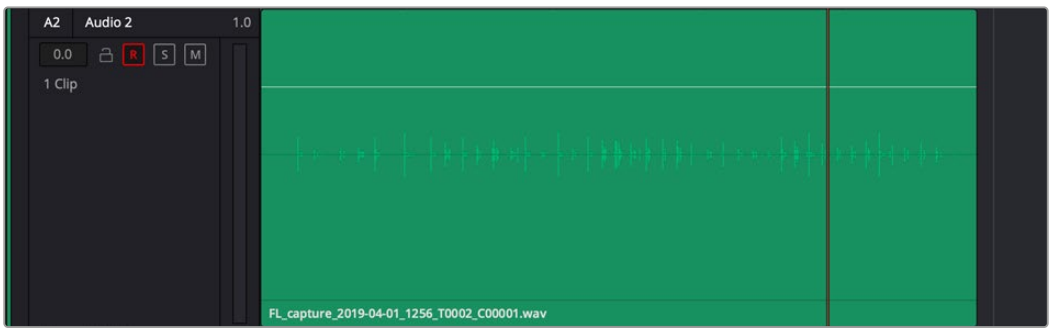
1 Make sure that the "Save clips to" field in the Capture and Playback panel of the Project Settings is correctly set up to record to the desired storage volume, using the Browse button, if necessary.

2 Click the R button in the track header of the audio track to which you applied the Foley Sampler, to put that track into Record Enable mode.

3 Click the Record button in the Fairlight toolbar.

4 While Fairlight records, use the keys or buttons of your MIDI controller to play sounds in sync to the picture on your display. When you're done, click the Stop button.

You should now have a recorded clip containing the sound effects you played, in sync to the picture. If they're a bit out of sync, you can always use the Elastic Wave audio retiming controls to tighten the sync without re-recording everything.

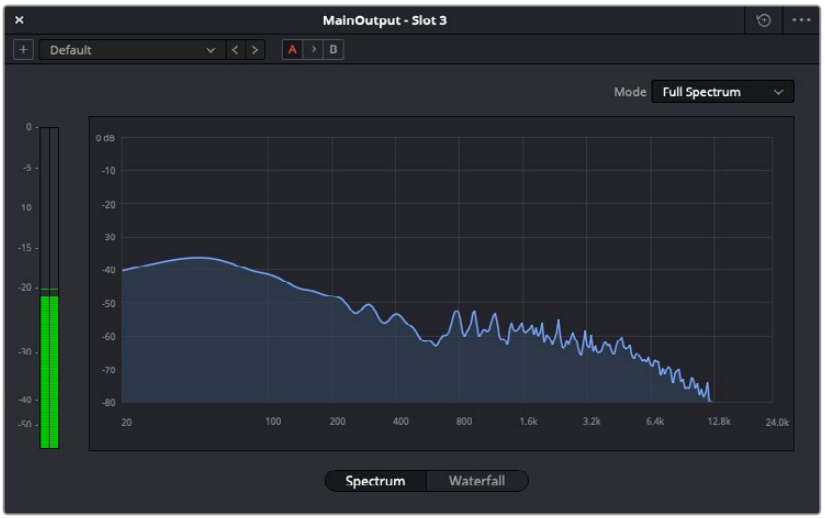


A new clip of audio created by recording sounds played via the Foley Sampler

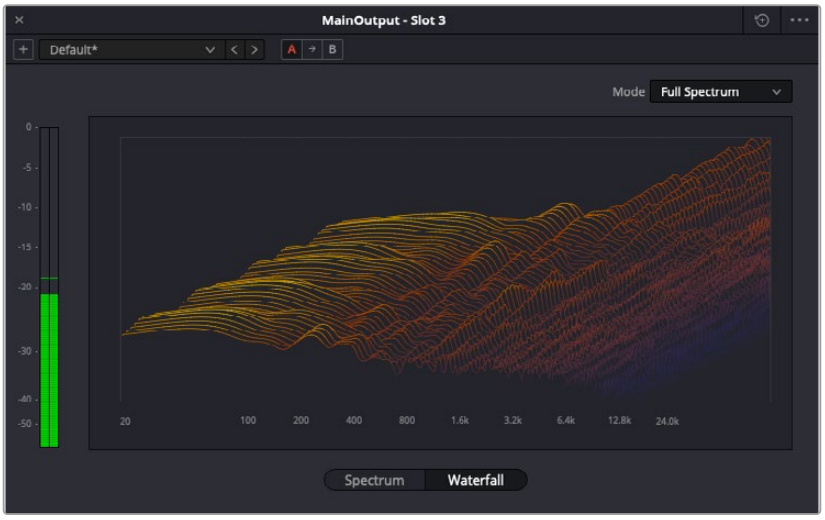
Frequency Analyzer

The Frequency Analyzer provides visual information about your clips or tracks as either a Spectrum or Waterfall graph to identify possible sonic issues so you can further sculpt your audio.

Options in the Mode menu in the upper right let you examine either the Full frequency range of the signal (default) or close-up views of the Low, Midrange, or High frequencies.



Frequency Analyzer Spectrum view

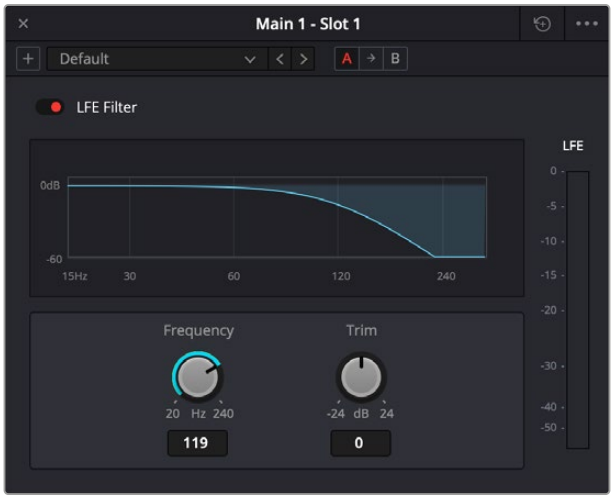


Frequency Analyzer plugin Waterfall view

LFE Filter

A low-pass filter that you can apply to a FlexBus or Main that's in a surround sound format, to feed low-frequency sound to an LFE channel as part of a surround sound mix. The filter will exclude any sounds above your chosen frequency setting to the audio that is sent to a sub-woofer in the LFE channel. It helps keep unwanted and unnecessary audio from being sent to the sub-woofer and increases playback clarity.

A Frequency control lets you choose which low frequency range you want to include, and a Trim control lets you set the level of the resulting LFE channel. If it is multi-channel but has no LFE channel available, such as a 5.0 format, then this plugin does nothing.



The LFE plugin

Limiter

The Limiter detects and reduces peaks in an audio signal, so the overall level can be boosted without clipping while reducing the dynamic range in a similar manner to a compressor.

This is a true peak limiter that can look 64 samples ahead of the input signal, allowing an extremely smooth limiting response.

The Input control lets you adjust the incoming signal level, while the Threshold and Release control when limiting occurs and for how long. The graph indicates which parts of the signal are being affected.

The Limiter plugin

Limiter controls

- **Bypass:** Toggles this plugin on and off.
- **Input Meter:** Shows the level of the incoming signal.
- **Input Level:** This control lets you adjust the incoming signal level within a range of -18 dB to +18 dB. Activating the Soft button causes the limiter to use a gentler attack.
- **Ceiling:** This determines the threshold (level) at which the Limiter starts reducing the input signal. When set to -24 dB, any signal above that level is limited. When set to 0 dB, no limiting occurs.
- **Release:** This determines how long the limiting (signal reduction) takes place. Setting this control to 0.01 milliseconds results in a very fast release time, while the longer release time of 1000 milliseconds is the slowest.
- **Reduction Meter:** This shows the amount of level (gain) reduction applied to the input signal.
- **Output Meter:** Shows the output level after the limit.

Limiter Sidechaining

The Fairlight FX Limiter supports sidechaining, which lets you temporarily lower the level of a target track or bus using the audible signal from a source track or bus.

This is very helpful when multiple tracks are “fighting” for space in a mix because they share some or all the same frequency range. For example, a track or bus with dialogue and a bus or track with traffic and crowd noise.

Essentially, this is another form of “ducking” where, in the example above, the dialogue attenuates the traffic and crowd noise until the dialogue stops. This allows the voices to be heard more prominently in the mix.

Sidechain controls

Using the Limiter Sidechain

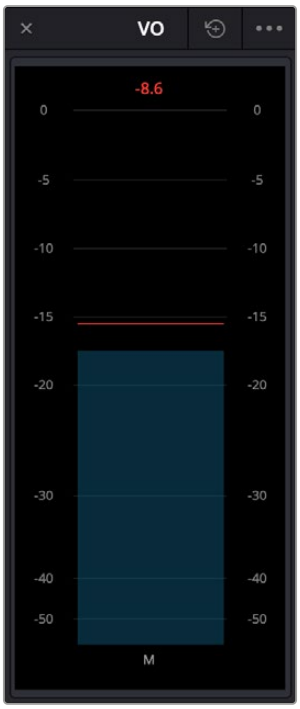
Carrying on with the example mentioned above:

1. Open the Limiter on the destination track or bus with the traffic and crowd noise.
2. Select the Dialogue track or bus in the source dropdown to the right of the Listen button.
    - This is the audio you’re using to attenuate the level of the target track.
    - Using a bus as the source lets you use multiple sources to trigger changes in your target track.

Clicking the Listen button lets you hear the incoming signal if you need to confirm that the correct input signal is coming into the Limiter. This button turns yellow when active.

Meter

A sample peak processing meter that's useful for temporarily adding a meter to a specific track or FlexBus. These meters are useful for instances where you want a large meter that focuses on a specific bus or track while you're working.



The Meter Fairlight FX

These meters are presented very simply, with a gray bar indicating level and a red peak line that holds for two seconds, which indicates the highest peak. A numeric reading at the top of the meter gives the exact level, in dB. This number continues to hold, indicating the loudest level measured for any given stretch of playback.

Meter can be resized by pulling from the bottom right and has the following controls located in the option menu:

- **Reset Peak on Play:** When enabled, the numeric peak level is reset every time playback stops and starts again. When disabled, the numeric peak level persists until changed by a higher peak.
- **Reset:** Resets the numeric peak level.

Modulation

An effect plugin. General purpose modulation plugin for sound effects or sound design. Four effects combine an LFO, FM adjustment, AM adjustment, Sweep and Gain filters to allow simultaneous frequency, amplitude and space modulation. In conjunction with the Rotation controls, simple Tremelo and Vibrato effects can be combined with auto-filter and auto-Pan tools in order to provide texture and movement to a sound.

An animated graph shows the results of adjusting the Modulator, Frequency, and Amplitude parameters of this plugin, giving you a visualization of the kind of modulations that will be applied to the signal as you make adjustments. Output meters let you see what level is being output.

The Modulation Fairlight FX

Modulation has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Modulator:** A low frequency oscillator (LFO), shown in blue in the animated graph.

  Shape: Specifies the shape of the LFO waveform that modulates the audio. Six options include Sine, Triangle, Saw1, Saw2, Square, Random.

  Rate (Hz): Adjust the speed of the modulating LFO. Lower settings result in warbling audio, while extremely high settings result in buzzing audio the timbre of which is dictated by the shape you've selected.

- **Frequency:** Frequency modulation (FM) of a secondary oscillator, shown as green in the animated graph.

  Level (%): Acts as a Dry/Wet knob controlling the amount of Frequency Modulation that's applied, intensifying or easing off the effect.

  Phase: Since each of the four primary effects within this plugin can be applied together, along with the fact that modulation with level components (Tremelo/Rotation/Filter) have the ability to combine or cancel out one another, phase controls are available. Altering the phase of an individual effect allows control of such interaction (e.g., cancel out a high level change, or offset a cancellation).

- **Filter:** Sweep and gain filters.

  Filter (%): Acts as a Dry/Wet knob controlling the amount of filter sweep and gain to additionally use to modify the signal. The amount you've selected is previewed in a 1D graph to the side.

  Tone: Adjusts the center frequency of sweep.

  Phase: Since each of the four primary effects within this plugin can be applied together, along with the fact that modulation with level components (Tremelo/Rotation/Filter) have the ability to combine or cancel out one another, phase controls are available. Altering the phase of an individual effect allows control of such interaction (e.g., cancel out a high level change, or offset a cancellation).

- **Amplitude:** Amplitude modulation (AM) of a secondary oscillator, shown as green in the animated graph.

  Level (%): Acts as a Dry/Wet knob controlling the amount of Amplitude modulation applied. (Disabled in Ring Modulation Mode.)

  Phase: Since each of the four primary effects within this plugin can be applied together, along with the fact that modulation with level components (Tremelo/Rotation/Filter) have the ability to combine or cancel out one another, phase controls are available. Altering the phase of an individual effect allows control of such interaction (e.g., cancel out a high level change, or offset a cancellation).

  Ring Modulation Mode: Enables a Ring Modulation effect (where the signal is multiplied by the modulator, rather than modulated by it).

- **Rotation:** These controls are only available when applied to a multi-channel track.

  Rotate: Amount of Rotation applied.

  Offset: Start offset of rotation in order to further place the signal in space.

  Phase: Since each of the four primary effects within this plugin can be applied together, along with the fact that modulation with level components (Tremelo/Rotation/Filter) have the ability to combine or cancel out one another, phase controls are available. Altering the phase of an individual effect allows control of such interaction (e.g., cancel out a high level change, or offset a cancellation).

- **Output:** Controls for adjusting the final output from this plugin.

  Dry/Wet (%): A percentage control of the output mix of “dry” or original signal to “wet” or processed signal. 0 is completely dry, 100% is completely wet.

  Output Level (dB): Adjusts the overall output level of the affected sound.

Multiband Compressor

A dynamics processor that compresses in highly definable frequency bands. The graph displays frequencies in Hertz horizontally and gain in decibels vertically. This allows for precise compression specific to defined frequency bands and is useful for taming only one or several parts of a signal.

The default setting of the Multiband Compressor

Each band has dynamics control in the determined frequency ranges of Low, Med, and High and are adjustable by pushing the intersection mark on the graph per band or by typing in a frequency.

Bands 1 – 4: Controls for each band.

- **Threshold:** Sets the maximum allowable output level. The default is –25dB. The range is from –50 to 0dB.
- **Gain:** Can add or attenuate up to 12 dB of gain.
- **Ratio:** Adjusts the compression ratio. This sets the gain reduction ratio (input to output) applied to signals that rise above the threshold level. The default is 1.5.0:1. The range is 1.0:1 to 7:1.
- **Limit:** Limits the output amount by up to 15 dB. The default is 4.5 dB.
- **Attack:** Adjusts the attack rate time constant of the sidechain detector. The default is 1.4 mS. The range is 0.1 to 100 mS.
- **Hold:** Keeps dynamics from being triggered again until a certain amount of time has passed, in mS (milliseconds). Defaults to 0mS. The range is from 0 to 4000 mS.
- **Release:** Adjusts how quickly the sidechain detector stops applying dynamics when a signal goes back below the threshold. The default is 150 mS. The range is 50 mS to 4.0 S.

Master: Controls for adjusting the final output from this plugin.

- **Gain (dB):** Adjusts the overall output level of the affected sound by adding or reducing 18 dB of gain.
- **Q:** Adjusts the width of affected frequencies. Lower values include a wider range of frequencies, higher values include a narrower range of frequencies.

Noise Reduction

A repair plugin designed to reduce a wide variety of noise in all kinds of recordings. A graph shows a spectral analysis of the audio being targeted, along with a purple overlay that shows what noise is being targeted. Two audio meters let you evaluate the input level (to the left) versus the output level (to the right), to compare how much signal is being lost to noise reduction. There are three default presets: De-Hiss, De-Rumble, and De-Rumble and Hiss.

The Noise Reduction Fairlight FX in action

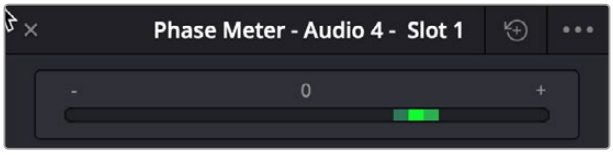
Noise Reduction has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Listen to Noise Only:** This checkbox at the top right lets you listen only to the noise that is being removed. This is very useful to determine if too much signal is being removed or if more noise attenuation can be applied.
- **Threshold (in dB):** Relates to the signal-to-noise ratio (SNR) in the source recording. Recordings with a poor signal-to-noise ratio will require a higher threshold value, resulting in more noise reduction being applied.
- **Attack (in ms):** Primarily useful in Auto Speech mode, this controls the duration over which the noise profile is detected. Ideally, the attack time should match the variability of the unwanted noise. A low value corresponds to a faster update rate of the noise profile and is useful for quickly varying noise; a high value corresponds to a slower update rate and can be used for noise that's more consistent.
- **Sensitivity:** Higher sensitivity values exaggerate the detected noise profile; the result is that more noise will be removed, but more of the dialogue you want to keep may be affected.
- **Ratio:** Controls the attack time of the signal profile relative to the attack time of the noise profile. A faster ratio detects and preserves transients in speech more easily, but the resulting speech profile is less accurate.
- **Frequency Smoothing:** Smooths the resulting signal in the frequency domain to compensate for harmonic ringing in the signal after the noise has been extracted.
- **Time Smoothing:** A toggle button enables smoothing of the resulting signal in the time domain as well.
- **Dry/Wet:** A percentage control of the output mix of "dry" or original signal to "wet" or processed signal. 0 is completely dry, 100% is completely wet.
- **Level:** To let you compensate for level that may be lost due to the noise reduction operation you're applying, this applies a pre-gain in, from -6dB to +18dB, just before the dry/processed mix.

Phase Meter

Phase cancellation is a phenomena where the waveforms of a stereo recording (for example a stereo recording of a music performance) go slightly out of sync with one another for whatever reason, and begin to cancel one another out in unpredictable ways, resulting in the audio sounding strange. This results in poor quality audio and can cause problems when you're trying to compress a mix to a distribution format such as AAF or MP3.

The Phase Meter plugin is a visual meter that lets you evaluate whether or not a signal is in phase and is meant to be applied to a bus so you may evaluate the phase of a mix and correct whatever problems may be occurring. The position of a green dot within a horizontal meter indicates the phase of the signal. When there's no signal or a signal on only one half of a stereo bus, the dot appears in the center (0). When the signal is out of phase, the dot appears all the way to the left (–). When the signal is in phase, the dot appears all the way to the right (+).



The Phase Meter plugin

Pitch

An effects plugin that shifts audio pitch without altering clip speed.

The Pitch Fairlight FX

Pitch has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Semitones:** A “coarse” adjustment that can shift audio pitch up to +/- 12 semitones.
- **Cents:** A “fine” adjustment that can tune audio pitch in +/-100th of a semitone.
- **Dry/Wet:** A percentage control of the output mix of “dry” or original signal to “wet” or processed signal. 0 is completely dry, 100% is completely wet.

Reverb

A spatial simulation plugin, capable of recreating multichannel reverberation corresponding to rooms of different sizes, adjustable via a graphical 3D cube control. This plugin lets you take a “dry” recording and make it sound as if it’s within a grand cathedral, an empty room, a tiled bathroom, or other spaces.

To understand this plugin’s controls, it helps to know that the signal follows three paths which are combined to create the final effect:

- A direct path.
- An early reflection path (ER) simulating early reflection rays obtained from the first multiple reflections on the walls, traveling from the virtual source to the virtual listener.
- A late reverberation path (Reverb) simulating the behavior of an acoustic model of the room.

A graph shows an approximate visualization of the reverb’s effect on the frequencies of the audio signal.

The Reverb Fairlight FX

Reverb has the following controls:

- **Bypass:** Toggles this plugin on and off.
- **Room Dimensions:** By controlling the size of the virtual room a sound is to inhabit, these parameters simultaneously control the configuration of Early Reflection and Late Reverberation processing. The acoustic modes from this simulated room are computed and fed to Late Reverberation processing. The shape, gain, and delay of the first reflections are computed and then fed to Early Reflection processing.

  Height, Length, Width: Defines the dimensions of the reverberant space, in meters.

  Room Size: The calculated Room Width x Length, in meters.

- **Reverb:** Additional controls that further customize the configuration of Early Reflection and Late Reverberation processing.

  Pre Delay: Increase or negate the propagation time from the virtual source to the virtual listener. As a result, it modifies the initial delay time between the source signal and the first reflection.

  Reverb Time: Decay time of the Reverb tail. It controls the overall decay time of the acoustic modes from late reverberation processing.

  Distance: Modifies the distance between the virtual source and the virtual listener. It modifies only the configuration of early reflections processing.

  Brightness: Modulate the shape of the decay time over frequency. At maximum brightness, decay time is identical at any frequency. At minimum brightness, higher frequencies result in shorter decay time and therefore duller sound.

  Modulation: Adds random low-frequency phase modulation from the tapping point of ER processing. At 0%, modulation is not used.

- **Early Reflection Tone:** Four post equalization controls modify the tone of early reflections to suit a particular room's characteristics.

  Low Gain: Amount of gain added to the low frequency.

  Low Frequency: Frequency range of 150 Hz to 500 Hz.

  High Gain: Amount of gain added to the high frequency.

  High Frequency: Frequency range of 1k Hz to 16k Hz.

- **Reverb Tone:** Four post equalization controls modify the tone of the reverb tail to suit a particular room's characteristics.

  Reverb Tail Low Gain: Amount of gain added to the low frequency.

  Reverb Tail Low Frequency: Frequency range of 150 Hz to 500 Hz.

  Reverb Tail High Gain: Amount of gain added to the high frequency.

  Reverb Tail High Frequency: Frequency range of 1k Hz to 16k Hz.

- **Output:** These controls recombine the three audio processing paths into a single output signal.

  Dry/Wet: A percentage control of the output mix of "dry" or original signal to "wet" or processed signal. 0 is completely dry, 100% is completely wet.

  Direct Level: The amount of the direct level to mix into the final signal.

  Early Reflection Level: The amount of early reflection to mix into the final signal.

  Reverb Level: The amount of reverb to mix into the final signal.

Soft Clipper

The Soft Clipper is a limiting processor that reduces the output level above a defined threshold in a rounded manner so that peaks are more cleanly attenuated. The Soft Clipper plugin will impart saturation effects when pushed hard above the threshold, allowing for the introduction of warmth and subtle distortion to the sound. A graph shows the shape of the curve adjustment this plugin makes to the audio.

A soft clipper is often combined with a standard limiter in order to increase perceptual loudness of material without imparting harshness.

The Soft Clipper Fairlight FX

- **Threshold:** Introduces input gain to the signal prior to hitting the clipper, forcing audio peaks over the threshold by that amount. As such, it will drive the saturation and distortion.
- **Shape:** The shape of the clipper can be varied to change the character of the soft clipper from full soft-clipping (all the way right, where the peaks are rounded) to full hard-clipping (all the way left, where the peaks are squared off).
- **Output Level:** Lets you adjust the output gain to compensate for signal lost during soft clipping, if necessary.

Stereo Fixer

A simple plugin designed to fix stereo source material in cases where only one side of a stereo signal was recorded, where one side of a stereo recording is a different level to the other, or where the stereo channels have been incorrectly Left/Right swapped.

This plugin can also be used as a “Mid/Side” decoder, for recordings that were made using this microphone technique.

> This plugin is for stereo clips only.

The Stereo Fixer Fairlight FX

- **Format:** The input processing mode you want to use to fix the stereo output.

  Stereo: (Default) No format conversion is performed.

  Reverse Stereo: Swaps the Left and Right side.

  Mono: The output from the plugin is a mono mix of the two inputs.

  Left Only: The left input is sent to both left and right outputs.

  Right Only: The right input is sent to both left and right outputs.

  M/S: The left output is the left (Mid) input minus the right input (Side). The right output is the left (Mid) input plus right input (Side).

- **Left/Right Gain:** Lets you apply independent gain on the left or right outputs. This gain is applied after (post) the input processing mode.

TIP: For a comprehensive M/S decoder solution, simply chain two Stereo Fixer plugins together. Use the first unit to control the Side signal level, thus controlling the width of the second unit (set to M/S).

Stereo Width

An enhancement plugin that increases or reduces the spread of a stereo signal in order to widen or reduce the separation between channels. If this plugin is added to a Mono channel, it will be disabled, as there is no stereo width to either distribute or control.

A graph shows the currently selected width of stereo distribution as a purple arc, while inside of that graph a stereo meter shows the Left and Right distribution of the audio signal. Two audio meters measure levels, an Input meter to the left, and an Output meter to the right.

The Stereo Width Fairlight FX in action

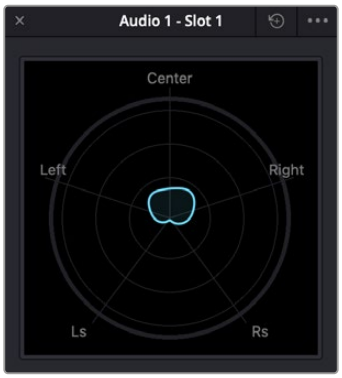
Stereo Width has the following controls:

- **Width:** Lets you control the spread of the stereo output. Settings range from 0 (Mono) to 1 (Stereo) to 2 (extra wide stereo).
- **Diffusion:** Adds more complexity to the output.
- **Sparkle:** Adds more high frequencies to the spread.

Surround Analyzer

The Surround Analyzer is a graphical meter that shows a spatial image of the audio being measured, rather than a typical bar graph meter. Due to its changing shape because of the signal being played, sometimes it is referred to as the “jellyfish meter.”

This type of metering is very useful; rather than relying on bars to indicate the directions in which audio is radiating, you can clearly see the relationship of all of the channels to one another.



The signal here is radiating more to the right, indicating the panning of the audio.

Vocal Channel

An enhancement plugin for general purpose vocal processing consisting of High Pass filtering, EQ, and Compressor controls.

Side by side EQ and Dynamics graphs are presented above the controls. An output audio meter lets you monitor the final signal being produced by this plugin.

The Vocal Channel Fairlight FX

Vocal Channel has the following controls:

- **High Pass:** Enabled by a toggle, off by default. Has a single frequency knob that sets the threshold below which frequencies are attenuated to reduce boominess or rumble.
- **EQ:** A three-band EQ for fine tuning the various frequencies of speech, enabled by a toggle, including Low, Mid, and High Mode, Frequency, and Gain controls

  Low/Mid/Hi Mode: Lets you choose from different filtering options to use for isolating a range of frequencies to adjust. Different bands present different options.

  Low/Mid/Hi Freq (Hz): Lets you choose the center frequency to adjust.

  Low/Mid/Hi Gain (dB): Lets you boost or attenuate the selected frequencies.

- **Compressor:**

  Threshold (dB): Sets the signal level below which compression occurs. Defaults to -25dB. The range is from -40 to 0dB.

  Reaction: Adjusts how quickly compression is applied when a signal exceeds the threshold. The default is 0.10.

  Ratio: Adjusts the compression ratio. This sets the gain reduction ratio (input to output) applied to signals which rise above the threshold level. The default is 1.5:1. The range is 1.1 to 7.0.

  Gain (dB): Lets you adjust the output gain to compensate for signal lost during compression, if necessary.

Chapter 179

Audio Meters and Audio Monitoring

The Meters panel at the top of the Fairlight page provides a visual reference of the track levels in your mix, specialized meters showing the busses, meters for monitoring mix and loudness, and a video Viewer for seeing the current project as you work.

This chapter describes the use of these meters, and provides information about the different options that are available.

The Monitoring Panel

Turning on the meters in the UI toolbar displays the Monitoring panel that runs along the top of the Fairlight page, which shows all of the audio meters that correspond to the tracks in the Timeline, as well as the Bus meters that correspond to the Mains, Subs, and Aux busses of your mix, the Control Room meters, and a video viewer.

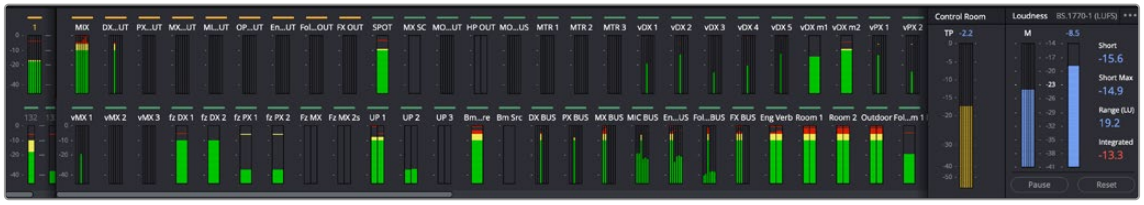
The Monitoring panel

With the increased track counts necessary for immersive audio, DaVinci Resolve gives you options for extra metering so you can see more tracks in real time.

Right-clicking anywhere on the meters opens a menu that lets you choose between viewing them as a single-row or double-height Track display. This menu also allows you to choose between narrow or wide meters. When using the wide meter view, double-clicking anywhere on the Tracks meters panel switches between single-row and double-height view.

Hovering a mouse below the Tracks panel reveals a cursor that lets you change the height of the Monitoring panel.

The Compound meters and the Bus Output meters can also be resized by hovering on the right side of the Loudness meter and dragging to the desired dimensions.

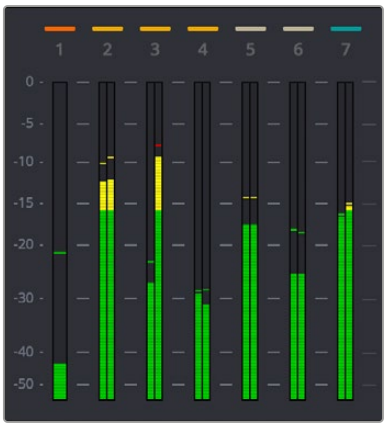


The double-height Monitoring panel

Track Meters and Monitoring Controls

At left, a row of audio meters corresponds to the channel strips of the Mixer, one meter for every audio track in the timeline. Each track displays the number of meters that corresponds to that track's audio mapping, with mono tracks having a single audio meter, stereo tracks having two, 5.1 tracks having six, and so on.

Each track and bus meter (with the exception of the Loudness meters) display RMS (root mean square) levels against a dB scale. A single line indicating the maximum value at any given moment in time is held briefly just above the current RMS levels, which appear as a solid bar extending from the bottom of the meter. RMS meters display a weighted “average” representation of the audio level that’s closer to the way audio is actually perceived, although not as accurate in measuring perceived loudness as the loudness meters discussed later in this section.



Track audio meters with different numbers of meters depending on that track’s audio mapping

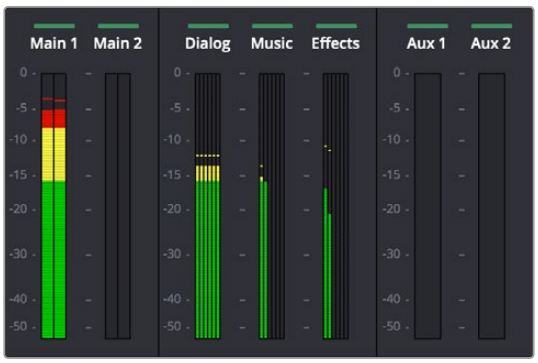
The peak meter at top

Each meter bar is color coded to indicate three different sound level “zones,” from low to medium (green) to moderately high (yellow) to very high (red).

Each meter is identified by the track number it represents (track names are not shown over track meters) as well as the color of that track.

Bus Meters

To the right of the track meters are the bus meters, in which all user-created mains and busses appear, separated by type, and each displaying the number of meters that corresponds to that track’s audio mapping. These meters allow you to monitor the sum of all tracks that have been routed to a particular bus, as you can on bus channel strips.



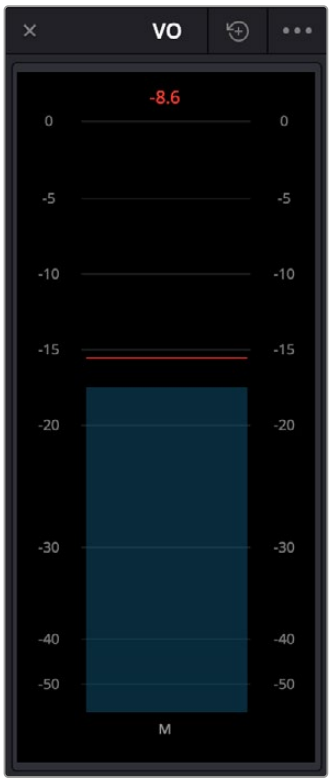
Bus meters for the Mains, Subs, and Aux busses

Meter Plugin

There is a Meter plugin available for temporarily adding a meter to a specific track, FlexBus, or when using fixed busing to Sub, Aux, or Main. These are sample peak processing meters that are useful for instances where you want a large meter that focuses on a specific bus while you're working.

These meters are presented very simply, with a gray bar indicating level and a red peak line that holds for two seconds, which indicates the highest peak. A numeric reading at the top of the meter gives the exact level, in dB. This number continues to hold, indicating the loudest level measured for any given stretch of playback. The option menu in this meter's floating window presents different settings you can choose.

For more information, *see Chapter 178, "Fairlight FX."*



The Meter Fairlight FX

The signal here is radiating more to the right, indicating the panning of the audio.

Surround Analyzer

The Surround Analyzer is a graphical meter that shows a spatial image of the audio being measured, rather than a typical bar graph meter. Due to its changing shape because of the signal being played, sometimes it is referred to as the "jellyfish meter."

This type of metering is very useful; rather than relying on bars to indicate the directions in which audio is radiating, you can clearly see the relationship of all of the channels to one another.

Compound Meters and Output Bus Selection Menu

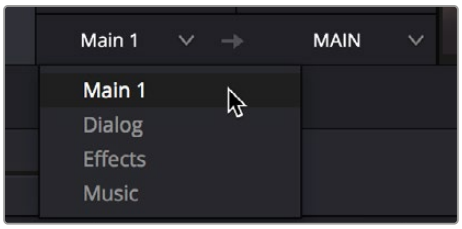
The compound meters, to the right of the bus meters, consist of Control Room meters and Loudness meters, shown side-by-side to provide a comprehensive analysis of your overall audio mix. Below, dropdown menus let you choose which bus you want to monitor, as well as which set of speakers you want to use to do the monitoring.

The Control Room meters (at left) and Loudness meters (at right)

Monitoring Menus

Bus Monitoring Menu

The bus monitoring dropdown menu determines which bus is monitored by your audio output (speakers or headphones), and thus which gets analyzed by the compound meters, letting you choose which bus you want to monitor as you work. You can choose one of your mains or any other bus (or track) you've set up that you want to focus on for more detailed work.



The monitoring menu lets you choose which bus you want to monitor while working.

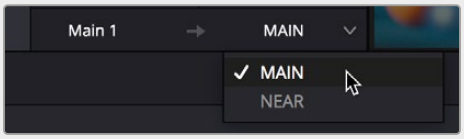
Speaker Set Monitoring Menu

To the right of the Monitoring menu, the output is set to "Auto" by default (if you have Automatic speaker configuration checked on in Preferences > Video and Audio I/O > Audio I/O). This means that your basic speaker set up is routed to the stereo or surround output your hardware supports automatically and can't be altered.

Monitoring with Multiple Speaker Sets

If you want to manually configure multiple speaker sets, unchecking the automatic speaker configuration preference will display a dropdown to the right and lets you choose one of the available sets of speakers once they have been configured in the Video and Audio I/O panel of the System Preferences. This gives you the flexibility to quickly compare your mix on a variety of speakers and configurations to see how it holds up in different situations.

For more information on configuring different speaker setups, *see Chapter 4, "System and User Preferences."*



The monitoring menu lets you choose which bus you want to monitor while working.

Control Room Meters

The mustard-colored Control Room audio meters show the sum of all audio channels that are routed to the currently selected bus being monitored (as selected in the dropdown menu below). These are peak meters measured in dBFS.

A true peak audio measurement is displayed at the top of the Control Room meter.

Loudness Meters

The set of meters all the way to the right are the Loudness meters, which consist of a set of two graphical meters and a numerical readout. This lets you keep track of the "integrated loudness" of the overall mix, which is the standard that all contemporary mixing specifications refer to when specifying client deliverables. Unlike the RMS audio meters found in the Timeline or Mixer, which measure audio in dB, Loudness meters do a different kind of analysis, measured in LUFS (loudness units relative to full scale).

What Is LUFS?

LUFS measurements evaluate sound levels that are averaged over time referenced to full scale. Full scale is the loudest level a digital audio system can handle before overloading ("clipping"). LUFS allows totally different types of program material to be matched in perceived level by human ears and has become the standard way that mixes are measured for final delivery of your program material. LUFS are shown as negative numbers, such as -23, -14, etc., because the level is referenced to full scale (digital 0).

Loudness Meter Options

Two options in the General Options of the Project Settings let you customize the Loudness meters.

- **Target Loudness level:** Lets you set the LUFS value that's used as a reference level for loudness metering. Defaults to –23 LUFS, which conveniently makes the display of these meters scale similarly to traditional audio meters that you're already used to.
- **Loudness Scale:** Lets you choose which scale you want to use with which to measure the meters. Options currently include the default of EBU +9 Scale (–18 to +9), and EBU +18 Scale (–36 to +18).

Support for Multiple Loudness Standards

The Loudness Meter can be switched among a variety of international industry-standard loudness monitoring standards. The standard you choose uses the integrated loudness value (along with a specified tolerance defined by each selected standard) to indicate whether or not the current mix level is of acceptable loudness via color coding of the Integrated Loudness value, and in the Integrated Loudness graph described below. Blue values indicate loudness levels that are below tolerance, yellow indicates loudness values that are within tolerance, and red indicates loudness values that are above tolerance.

The built-in standards you can switch among include the following:

- **BS.1770-1:** An older loudness standard used by DaVinci Resolve version 15 and before.
- **BS.1770-4:** The most up-to-date loudness standard as of DaVinci Resolve 16; the algorithms specified by this standard govern the other standards that are listed below in this dropdown menu.
- **ATSC A/85:** The American standard for acceptable loudness in broadcast.
- **EBU R128:** The European standard for acceptable loudness in broadcast.
- **OP-59:** The New Zealand and Australian standard for acceptable loudness in broadcast.
- **TR-B32:** The Japanese standard for acceptable loudness in broadcast.
- **AGCOM 219:** The Italian standard for acceptable loudness in broadcast.
- **NETFLIX:** The Netflix standard for acceptable loudness in broadcast.
- **YouTube:** The YouTube standard for acceptable loudness in broadcast.
- **Disney 2.0:** The Disney 2.0 standard for acceptable loudness in broadcast.
- **Disney 5.1:** The Disney 5.1 standard for acceptable loudness in broadcast.

All of these loudness standards are available for off-line readings as well, using the Loudness Analyzer described in the next section.

NOTE: The target peak meter now uses the BS.1770-4 standard for measuring maximum "true peak," which means that this meter is capable of measuring "inter-sample peaks," rather than only the peaks at each sample of a waveform.

Graphical Loudness Meters

Two separate meters give you a dynamic graphical measurement of the loudness of the selected bus being monitored according to the loudness standard you've selected, which determines how to analyze the subjective loudness of a given audio mix for purposes of compliance with required broadcast quality control (QC) standards.

- A steel-blue meter labeled M (for momentary) has as many channels as the selected bus you're monitoring, excluding the LFE channel(s) of surround formats, which aren't factored into loudness metering. This meter measures LEQ (equivalent sound level), within a 400ms window following the playhead as measured every 100ms. This lets you evaluate the LUFS (Loudness Units Full Scale) level of the mix at the current frame as you play. This discrete-channel analysis is used to calculate all other values of the loudness metering system.
- A second steel-blue mono meter to the right displays the sum of all channels in the M meter, displayed in LU (loudness units). The number value displayed at the top of this meter is the maximum LU value that's been analyzed during any stretch of timeline playback. This value is held until it's reset, either by stopping and initiating playback a second time while Link to Playhead is enabled, or when you click the Reset button at the bottom of the loudness meter area.

Numeric Loudness Meters

A set of values to the right of the meters give running reports on the audio level of your mix. While the graphical meters are useful for analyzing your mix as you work, these numeric readouts are particularly valuable for providing the strict information you need to adhere to written QC standards. Their meaning is as follows:

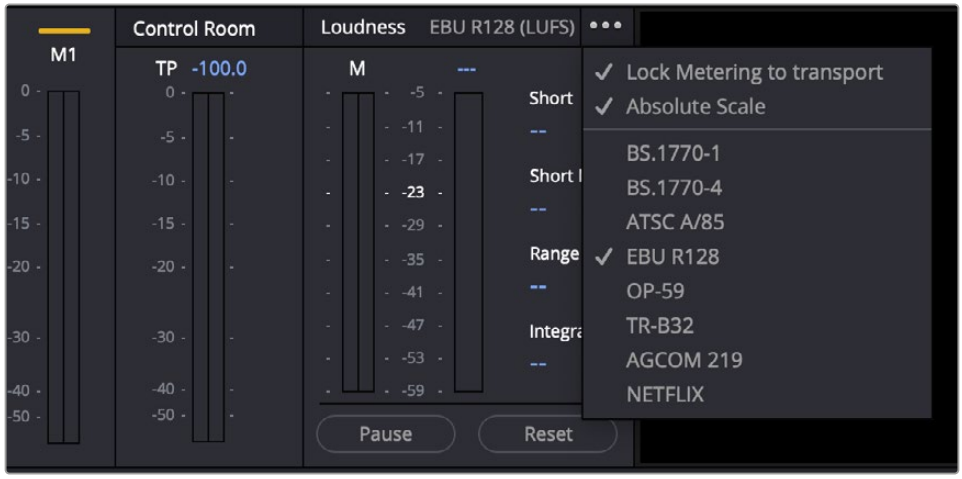
- **Short:** Measures the average LU level over a 30-second window following the playhead.
- **Short Max:** Shows the maximum level over the same 30-second window. This analysis is required by EBU R128.
- **Range:** Measures the dynamic range of the Loudness of your mix (in LU, or loudness units), which is the difference between the average soft and average loud parts of your mix. Analyzes the overall loudness over a played range of the mix, discounts the lowest 10% and highest 5%, and then gives a standardized expression of the difference between the remaining soft and loud levels that were analyzed. The window of analysis is as long as you've been playing. This analysis is required by most QC specifications.
- **Integrated:** Measures the LUFS value of the portion of the range of the mix you've played through. As you play, this integrated value accumulates. This analysis is required by most QC specifications.

Absolute Scales and Dialog

While some users prefer to measure their levels to correspond to a relative scale of "0," similar to a VU meter where the needle rides above the "0," others want to see the absolute measure of the amplitude in LUFS and true peak. By default, the Loudness meter is set to relative scale, but you now have the option to choose between relative scale and absolute scale in the Loudness meter.

Relative scale in the Loudness menu is relative to the selected scale, so a loudness unit of 0 corresponds to the target of the chosen measure type. For instance, if EBU R128 is selected, whose target measure is -23dB LUFS, the "0" LU (Loudness Unit) is -23dB. If ATSC A/85 is chosen, whose target is -24dB, then that becomes the corresponding equivalent of the relative LU of 0.

When using the absolute scale, the Loudness meter displays the increments to reflect the chosen measure type. In absolute scale the EBU R128 meter will display -23 instead of the relative scale's 0.



The option in the Loudness panel reveals the various measure types as well as the option for absolute scale.

Using the Loudness Meters

When using the Loudness meters to do a structured analysis of your mix to determine QC adherence, a group of controls let you determine when analysis begins and ends.

- **Lock Metering to Transport:** This setting is found in the compound meter option menu. When enabled, all loudness metering analysis is automatically reset whenever you move the playhead to another location in the Timeline. This is useful when you're spot-checking different parts of your mix, or working on a particular scene. Uncheck this option if you want the measurement of playback to that point in the Timeline to remain.
- **Absolute Scale:** An absolute measure of the selected scale type.
- **Pause and Reset buttons:** When you're doing a formal analysis of your mix, the Reset button lets you reset all currently accumulated analyses, and the Start button initiates loudness value accumulation. If you need to stop playback briefly to do something else, you can click Pause, and then click Resume when you're ready to continue the analysis.

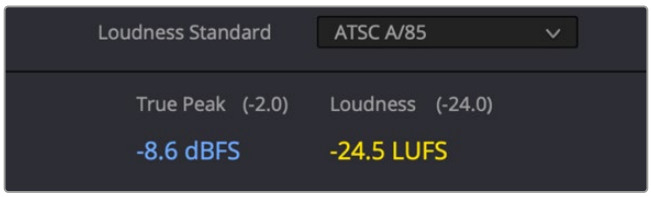
Offline Loudness Analyzer

Users also have the ability to analyze an audio file's loudness offline. This is a fast way to measure loudness in imported audio files or bounced mixes.

To initiate offline loudness analysis:

- Right-click the file in the Timeline, and choose Analyze Audio Level from the contextual menu. A dialog box displays the available options for measurement.

All of the measurements available in the real-time loudness meter are accessible in the dropdown menu inside the Analyze Audio Level panel. When the analyzer mode is chosen, the target measurements for that mode will display next to the reading in parenthesis. Once you have clicked the analyze button, the results will display in the panel next to the chosen mode's target measurement values.



Select the audio file, choose the desired analyzer mode, in this case EBU R128, and click analyze.

Visualizing Loudness Monitoring

When you show the track of a Main bus in the Timeline, as long as the track is high enough (ahem, tall enough), you can show or hide a series of "Loudness History" curves to visualize the loudness analysis of the mix on that bus over the duration of the mix.

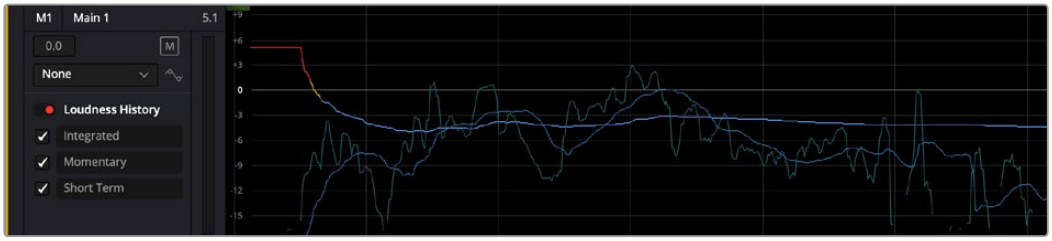
The available curves are:

- **Integrated:** A thick curve shows the averaged "integrated" loudness analysis of the current mix, which is a measurement that's taken from the beginning to the end of playback. This graph is the primary gauge of whether or not measured loudness is acceptable. The color of each segment of this curve indicates whether that part of the mix is "to spec." Blue indicate loudness levels that are below tolerance, yellow indicates loudness values that are within tolerance, and red indicates loudness values that are above tolerance. By evaluating the colors of the curve, you can easily spot which parts of your mix might need adjustment to meet the necessary specification.

- **Momentary:** A measurement of the loudness measured in the past 400ms, shown by a thin green-blue curve, which provides an analysis of transient level changes.
- **Short Term:** A measurement of the loudness of the past 3 seconds, shown by a thin blue line, which provides a more averaged analysis than the Momentary curve, yet still indicates the dynamics of the mix.

To show the loudness history for Main 1:

1. Open the Automation controls by clicking the automation button on the Fairlight toolbar.
2. Open the Index, and click the eye button for the Main you want to see in the Timeline. Loudness History appears as an option in the track header controls as long as the track is tall enough to show the controls. These controls will be hidden on short tracks.
3. Turn on the Loudness History toggle, and check the curves you want to see. The Integrated, Momentary, and Short Term loudness analyses can be individually displayed or hidden, to expose overlapping graphs in that track in which you can see your program's loudness over time.



Viewing the loudness graph of the mix going out of a Main

NOTE: Currently, loudness history is only supported for Main 1.

Metering Options

DaVinci Resolve has a variety of metering options that allow you to tailor metering to your workflow. The settings appear in Project Preferences > Fairlight on the Audio Metering pane, but they affect mixer, Fairlight effects, or master metering on the Cut and Edit pages.

Level Metering Options

You can chose the response characteristic of the level meters for channel strips and Fairlight FX.

The Meter Type dropdown allows you to choose between IEC 60268-18, Digital VU, and Custom response characteristics. Both meter types have separate "hold and fall" metering, allowing you to see the highest peak that is reached.

- **IEC 60268-18:** A digital PPM-type meter with reference standard of -18 dBFS, a fast response to peaks, and a slower release characteristic. This is the default in DaVinci Resolve and is used in all Blackmagic Design software and hardware products.
- **Digital VU:** A dual-value meter, showing the peak level as a single segment with fast ballistics, and the RMS (volume unit) as a bar graph. It has a far faster quasi linear decay characteristic, making it easy to monitor average levels while allowing sounds with quick transients and decays to be more easily tracked. This option can be best for audio editing and mixing.
- **Custom:** Allows each aspect of the meter response to be chosen, including level detector, scale, peak, deck and peak indication.

Pre-fader Metering

By default, “Pre fader metering on tracks” is unchecked (disabled), setting the metering on channel strips to be post (after) the fader level and mute button. For example, if the source audio file has peaks that are hitting -2 dBFS, and the channel fader is lowered from 0 to -10, then the peaks that show on the meter will now be at -12.

When pre-fader metering is on, the metering point is set to be before the fader, and is not affected by the fader’s position. However, the meter is affected by clip gain settings or key framing as these level changes occur before the clip’s signal enters the mixer’s signal path.

With pre-fader metering, you could lower the fader to be fully off (minus infinity) and the meter will still read the level of the source signal. This allows you to always be aware of the source signal and what it is doing before being altered by mixer’s controls or processing.

Many video editors prefer to work with post-fader metering, but most audio mixers prefer to work with pre fader in order to be aware of what the actual source level is at any time.

Solo and Pre-fader Metering

When pre-fader metering is enabled, soloing one or more tracks will show a lighter “ghost” version of meter activity on non-soloed tracks, allowing you to always see audio levels on tracks that are muted by the soloing process. This makes it easy to focus on tracks that are actually audible while still seeing activity on those that are not.

If pre-fader metering is off (the default), when one or more tracks are soloed, no metering occurs on tracks unsoloed tracks.

Pre-fader metering with light shaded meters on non-soloed tracks

Target Loudness Level

Allows the target loudness level in LUFS for the master Loudness meters to be set to your desired output target level. For example, DaVinci Resolve’s default loudness standard target is -23 LUFS, but the YouTube target LUFS specification is -14 LUFS. If -14 LUFS is set, the “0” mark on the loudness meter scale moves to this level, allowing you to focus your master mix levels towards that loudness standard.

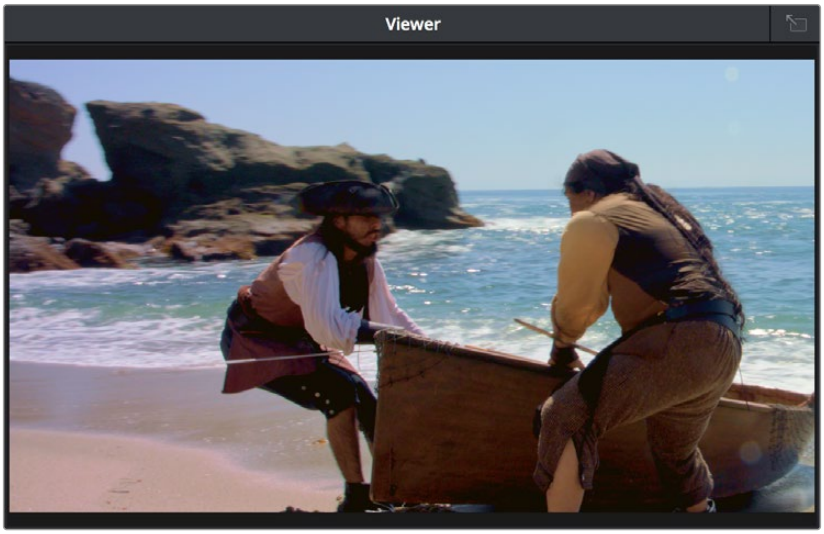
Viewer

A small viewer to the right of the Monitoring panel shows the frame of video at the position of the playhead. This is the same image that's output to the external broadcast display of your workstation if you have one connected.

The Viewer lets you see the picture you're mixing to.

Clicking the Expand Viewer button at the bottom right-hand corner lets you open the Viewer into a floating window, which you can then position anywhere you want.

To close the floating Viewer, click the Dock Viewer button at the upper right-hand corner of the floating viewer window.



Click the button at the upper right-hand corner to dock the Viewer again.

Cinema Viewer on Fairlight Page

Sometimes when you need to verify lip sync, sound effects sync, or simply review a new section of a mix you've been working on, it helps to watch the visuals of the program full screen as you listen to your mix. You can now set the Fairlight page Viewer to Cinema Mode by choosing Workspace > Viewer Mode > Cinema Mode (Command-F).

Chapter 180

Signal Flow Diagrams

The diagrams in this chapter describe the Fairlight audio processing signal flow in DaVinci Resolve. They're intended for people who want an in-depth understanding of how audio is processed.

Chapter 181

Immersive Audio Workflows

DaVinci Resolve offers substantial support for object and channel-based surround or immersive audio formats.

This chapter describes how to set up and mix with these formats when mixing in the Fairlight page.

About Immersive Audio Formats

Surround audio formats use multiple audio channels to position sound sources around the listener to add a creative dimension to sound design. Their simplest formats, such as 5.1 and 7.1 surround, allow the mixer to send varying amounts of any track to a combination of speakers, placing the audio in various positions around an auditorium or living room, as centered in front, ambient from the rear, or weighted towards the left or right of the listener.

More sophisticated immersive formats such as Dolby Atmos™ or Ambisonics define a virtual soundstage where you can mix the resulting audio to match the speaker configuration or listening setup.

Dolby Atmos

The traditional surround sound experience outputs a specific set of monitoring channels that requires a specific number of monitor speakers placed in particular areas of a room, which can position sound approximately within a ring around the listener. Dolby Atmos improves upon this by being an object-based sound system operating within a 3D immersive space that can accommodate a wider variety of different speaker configurations using more speakers positioned around the listener. This increases dimensionality with more precise sound placement, adding height channels to produce sound that comes specifically from above. DaVinci Resolve supports Dolby Atmos output render formats 5.1.4 to 9.1.6.

A practical example of this difference can be heard when panning in a 7.1 mix; since you're sending signals to specific points in a speaker array, those points are fixed. Although the physical size of rooms can be larger or smaller, the mix is always sent to those assigned point speakers, so the experience from room to room may be inconsistent. By comparison, Dolby Atmos gives re-recording mixers a way to mix to an idealized space instead of fixed speaker positions. This means a Dolby Atmos mix, when played in a Dolby Atmos room, takes into account the actual dimensions of the space, as well as the number of speakers that are used, to recalculate audio playback to suit that exact space and playback equipment, giving a more faithful recreation of the mix with much more specific sound placement, when necessary.

To give a clear example of the benefits of Dolby Atmos, think of a small theatre that has standard left, center, and right front-screen speakers. It then has four left surround and four right surround, four overhead left, and four overhead right. For this example, let's say you have sent a sound to the surround left in Atmos, positioned at about one-half of the distance from the screen.

Now move the Atmos mix to a much larger room with twice as many monitor speakers. The new theatre has eight left surrounds, eight right surrounds, eight overhead left, and eight overhead right. Playing in this new configuration, Atmos automatically calculates the ratio of the room and the new speaker array. In this example, when that sound is reproduced at one-half of the distance from the screen, Dolby Atmos calculates the ratio of the sound in relation to the new playback setup, so the listener hears exactly what the re-recording mixer intends.

> For this example, let's say to have that audio playing back at one-half of the distance from the screen in the small room, the audio is played on the second surround speaker on the left. When this same audio is played in the larger room, Atmos determines that the fourth surround speaker is one-half the distance from the screen. The importance is not what speaker the sounds are assigned to but rather where in space the sound should be heard. Atmos calculates the ratio of the playback spaces and monitor speakers to faithfully reproduce a mix, rather than assign sounds to a fixed speaker position.

Dolby Atmos Speaker Configurations

It is important to understand that the term Dolby Atmos isn't restricted to describing any particular speaker layout. Dolby Atmos is a complex metadata-driven system that interprets the audio from a configured Atmos mix, determines the playback system of the end user, and calculates the mix to fit each particular space and system. Assuming the possession of a Dolby Atmos compatible system, if a 7.1.4 Atmos mix is played by someone with only a two channel playback system, then it will intelligently down mix the 7.1.4 Atmos to stereo. If a user has a standard 5.1 monitor system, then the 7.1.4 Atmos soundtrack will down mix to five channel surround with a subwoofer.

The naming of the channel configurations in the Dolby Atmos format includes the height channels in the nomenclature. Channel configurations are presented as three digits separated by periods, such as 7.1.4, which is a typical speaker configuration. The first digit describes the number of main, or ear-height monitoring channels that surround the listener. The second digit describes the number of subwoofer channels. The third digit describes the number of height channels, which are speakers positioned on, or in the case of a soundbar, pointed at the ceiling.

An example of a 7.1.4 Atmos monitor speaker configuration:

- Seven surround channels
  - Left
  - Center
  - Right
  - Left Surround
  - Right Surround
  - Left Back Surround
  - Left Right Surround
- One Subwoofer
- Four height channels

Enabling Dolby Atmos

Atmos must be enabled by going into Preferences > Video and Audio I/O > Immersive Audio panel and turning on Enable Dolby Atmos. When enabled, the Change Track Type contextual menu when right-clicking on a track will then include the additional Atmos track types.

The Components of a Dolby Atmos Mix

Mixes created in Atmos have several specifically identified components. These work together to create an immersive mix, but each element allows the Dolby Atmos system to fit the sound specifically to the space and speaker configuration during playback.

These consist of:

- **The Bed track:** Contains the bulk of mixed audio, including dialog, ambient sound effects, and music. These sorts of sounds will contain panning information, but the panning will be general. Wind, traffic in the distance, room tones, and sync dialog would all most likely fall within the bounds of a standard bed track of 7.1.2 or 5.1.
- **Object tracks:** Pinpoint the placement of sounds moving specifically across the immersive space. Users can use these specific tracks to create panning anywhere in the room. Sounds can fly through space, around a room from height channels, to side and back channels, mimicking the motion of objects on the screen. Object tracks use the Atmos metadata to do the calculations discussed in the last example. ADM files are Atmos exports used with the IMF file type as master deliverables, which are in the broadcast wave file format.

It's up to users to define which tracks are Bed tracks, and which are Object tracks; these track designations, are descriptions of what the tracks you create are going to be used for. Ultimately, it's up to the mixer which audio is organized on Bed tracks, and which is organized on Object tracks. Theoretically, users can create a mix consisting entirely of Object tracks if desired, but typically the mix would be split into beds consisting of generally panned sounds, and Object tracks for sounds requiring specific room placement.

Object tracks and height channels open up possibilities that were never possible prior to Atmos. Imagine a scene where a man is hiding from Police while a helicopter circles overhead, or a scene where kids are in a basement and are startled to hear loud footsteps above them. With Atmos, the audience can now experience these immersive sounds along with the characters.

These are real-world examples, but sound in animation, science fiction, and fantasy can explore space in ways that are only limited by the creator's imagination. Flying fairies or creatures can move about the space front to back, high and low. Perhaps there's a scene with a ship moving full speed ahead underwater, breaking up and out into the sky, flying and dodging weapons coming from all sides. Object tracks are ideal to pinpoint sound effects requiring spatial specificity, but more importantly, Atmos assures the re-recording mixer that the final choices made in the mix will be faithfully recreated from theatre to theatre, and from room to room.

NOTE: Buses feeding the Atmos master become beds, and Tracks feeding the Atmos master become objects.

Predetermined Dolby Atmos Master Rules

The first ten tracks in every Dolby Atmos Master are assigned as a bed by default. From there the default bed is a 7.1.2 bed, however, it can be designated to a 2.0 up to the 7.1.2 bed. There is no option to add objects to these first ten tracks. Starting at track eleven, the tracks that follow can then be made into various beds or objects as needed.

A simple way to think of this is that buses routed to the Atmos Master are treated as beds, carrying predefined multiple sources. An Atmos bed is a fixed surround format that can contain height channels. Objects, are generally mono but can send any format track that DaVinci Resolve supports and follow the metadata as a single object element. Objects routed to the Atmos Master are treated as tracks, carrying dynamic audio content and positional metadata. LFE will need to be sent to a bed, since objects are positional metadata. If the object is 5.1 for example, the LFE channel will need to be routed to a Bed bus in order to be rendered in the Atmos master.

The Dolby Renderer will render the file if it is dragged from the Media Pool into a track in the Timeline. In this case it will render the media with the embedded metadata to the master's output format. This is a simple way to monitor pre-mastered content and to perform simple actions, such as trimming or syncing for new packaging and deliverables.

When importing a Dolby Master file from the Fairlight menu, Fairlight > Immersive Audio > Import Master File, the resulting import will extract all of the audio and metadata for further content creation. This type of importing into Fairlight maps all of the metadata, tracks, beds, and objects from the master file into the Timeline, allowing you to adjust, process, and manipulate further, to rewrite panning, punch-in and add new media, and create a new Atmos Master.

Dolby Atmos files are a package of items. Simply linking files will not create an Atmos Master file. It is not possible, for instance, to take a rendered set of twelve tracks, link them, and then configure their outputs to a 7.1.4 Atmos bed. Note that 7.1.4 is not a Atmos bed type. Although this is the way typical PCM audio is linked and routed, it is not the case for Atmos content, which is far more than just a collection of tracks.

The renderer takes the 128 channels consisting of the beds and objects and renders it. Those channels are either internal sources or contained within the master file. A simple linked file will not play back through the Renderer. It must be played back as all linked files in Fairlight do, through the native monitor. The Dolby Atmos Renderer plays, renders, and extracts Atmos Master files. Fairlight allows for .atmos, ADM, and IMF file types to be imported and played through the Renderer.

NOTE: As mentioned above, the LFE can only be rendered in an Atmos master when routed as part of a bed due to the Dolby Atmos specification.

Dolby Atmos Integration

There is native Mac M1, Windows, and Linux support for the internal Dolby Atmos workflow including:

- Input
- Content creation
- Internal renderer
- Export of Dolby Atmos Master Files

There is a dedicated Dolby Atmos Master bus format which provides a master fader in the Mixer for the Dolby Atmos Renderer and is indicated by the Dolby logo in its header. It also provides a loudness history graph in its Timeline view with integrated, momentary, and short term loudness measures. In the Bus Format window you will see that there are no outputs from this track; it is a control for the Dolby Atmos Renderer.

Only a single master bus can be created, and it will always mirror the format and metering of the internal renderer. When there are no patches to the Dolby Atmos Sends, all sources routed to a Dolby Atmos Master bus will target the master, as with a traditional bus workflow. In this send workflow, buses become beds and tracks become objects.

For Mac and Windows machines, the integration of the external Dolby Atmos Renderer has been updated, providing a much closer integration when running an external workflow. This has unified the tools available within the internal renderer workflows with the external renderer. This includes:

- External Renderer discovery within the preferences.
- UI enable to switch between the internal and external workflow.
- Tally of the master connection state and master file status.
- Storage and recall of the program metadata within the DaVinci Resolve Timeline, including all input configuration, trims, down-mix, and binaural settings.
- Direct control of the metadata from the renderer and binaural controls within DaVinci Resolve and bi-directional control of that program metadata from the server.
- Tally of the input configuration within the Patch page.
- Multi-client workflow support, allowing multiple instances of DaVinci Resolve to run attached to the same server for larger workflows.
- Tally of the active bed and object assignments on the Dolby Atmos Sends within the Patch page. When assigning a bed or track to the Atmos Master on the Patch page, beds are indicated with a purple marking and objects are indicated with a green marking.

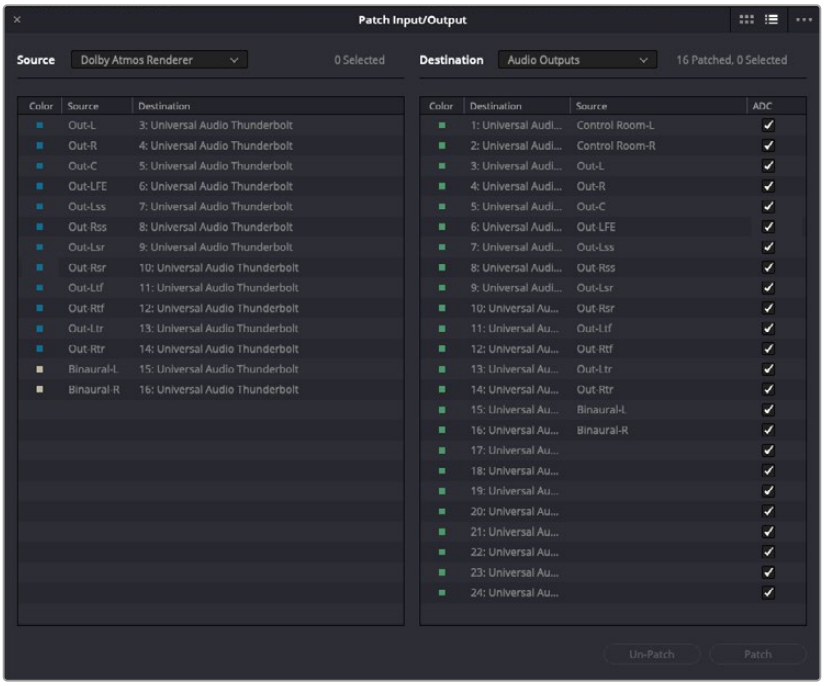
Binaural Audio Monitoring

You can monitor your Dolby Atmos Master in Binaural by choosing Binaural in the monitor section.

The Binaural monitoring option

Depending on your monitoring system, you can also create a parallel speaker monitoring set up with Binaural. For instance, you can create a 5.1. external monitor mix along with a binaural headphone mix.

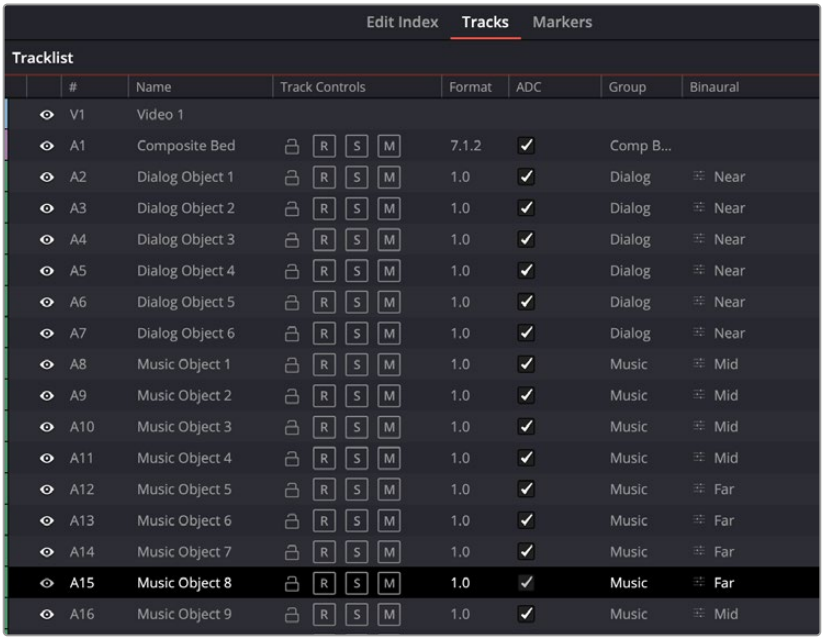
In Preferences > Video and Audio I/O, you can set Binaural to the headphone outs in the Audio I/O panel, and a 5.1 monitor in the Monitor Speaker configuration. Then, in the Patch Input/Output panel, you can route to the appropriate positional channels specific to your system and settings and also assign available channels for the headphones.



Using the Patch Input/Output to assign parallel binaural monitoring

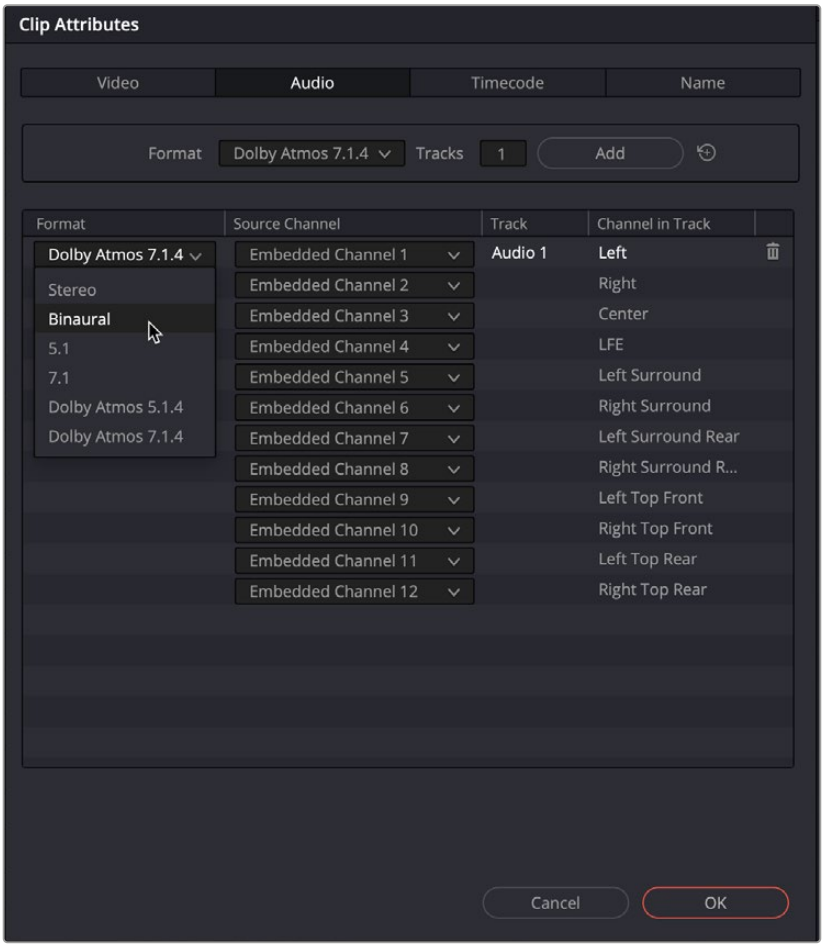
Binaural Render Options

Binaural rendering is a simulation of the distance between the sound source and the listener. In the Index there are options on how you can choose to render the binaural objects. The default option is Mid, but you can also choose Off, Near, or Far, depending on the desired rendering for binaural. These choices will all be stored in the Dolby Atmos file.



Binaural choices in the Tracks Index for assigning perceived distance

You can use Clip Attributes to render a Dolby Atmos Master in Binaural. Simply right click the file to open Clip Attributes, select Binaural, and then right-click to create a new Timeline with the file. In the example below, a 7.1.4 file will be rendered to a Binaural audio file.



Using Clip Attributes to render to a Binaural file

Ambisonics

Ambisonics is a full-sphere multi-channel immersive “adaptive” audio format that lets you position sounds in the horizontal and vertical planes.

Compared to other surround formats, Ambisonics transmission channels aren’t speaker-specific and represent a complete sound field captured by a specialized microphone for an accurate positional depiction of “sound in space,” or generated from channel-based sources via sophisticated encoders.

The flexibility of this audio format makes Ambisonics compatible with various speaker configurations, such as 5.1 and 7.1.4, headphones, and large arrays in multiple applications, including theme parks, art installations, video games, and virtual reality.

You can even work and mix between channel-based and Ambisonics formats, without the need for third-party audio plugins.

DaVinci Resolve Fairlight’s full Ambisonics support includes spherical panning, Ambisonic bussing, Fairlight, AU, and VST Ambisonics effect plugins, accuracy up to fifth order High Order Ambisonics (HOA), and channel and binaural decoding to headphones.

Ambisonic Orders

Ambisonics “orders” define the mathematical precision and number of discreet channels to represent the sound field, ranging from the first to the seventh order. First order uses four discreet audio channels, while higher orders use more channels, requiring greater processing power.

Although DaVinci Resolve Fairlight supports up to fifth order Ambisonics, requiring 36 channels, you can get great results using third order and 16 channels.

Ambisonic File Support

DaVinci Resolve supports Ambisonic files in WAV, BWAV, or .caf (including 1OA AMB and AmbiX) formats.

Adding a Media Pool clip to the timeline or creating a new timeline that refers to a clip creates a track of the appropriate type, matching the file’s Ambisonic order and channels.

Enabling Ambisonics

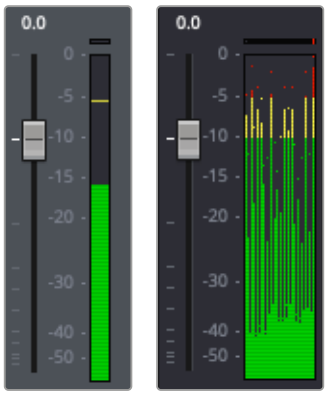
Ambisonics is enabled by going to Preferences > Video and Audio I/O and clicking the Enable Ambisonics checkbox in the Immersive Audio section.

Ambisonic Metering Options

Mixer and Track Header Meters

Fairlight Ambisonic metering utilizes a single, composite bar-graph meter in the Mixer, Track header, and Meter panel. Unlike other audio formats, they don’t correlate to specific speaker positions or levels we would track visually to determine what is happening with the signal.

Alternatively, you may want to use bar-graph meters that display Ambisonic signals as discrete, separate bus streams by choosing Fairlight > Immersive Audio > Ambisonics Channel Metering.



Default Ambisonics metering (left)
and Discrete Channel metering (right)

Ambisonics Metering

This Fairlight FX audio plugin offers two different visual metering options for analyzing your audio. The Ambisonics meter can be added to an audio track or bus via the channel strip's Effects section.

For more information about the Ambisonics Meter, *see Chapter 178, "Fairlight FX."*

Video Viewer Overlay

The Fairlight page also offers Ambisonic metering options as overlays on the Video viewer, allowing you to analyze the sound intensity against the picture.

To enable the Ambisonics Meter overlay:

- Activate 360 Viewer Mapping in the Video Viewer tools menu.
- Go into the Ambisonics Meter submenu, click On, and select one of the metering modes.

Enabling the Ambisonics Meter overlay

Ambisonic Effects

While most Fairlight FX plugins, such as the Multiband Compressor, Limiter, Reverb, and Channel Dynamics and EQ, are Ambisonic-native, DaVinci Resolve also supports compatible Ambisonic-native third-party AU and VST effects.

For more information on the Channel Dynamics and EQ plugins, *see Chapter 174, "Mixing in the Fairlight Page."*

For more information on Audio Effects plugins and how they can be used in DaVinci Resolve, *see Chapter 177, "Audio Effects."*

For more information on individual Fairlight FX plugins, *see Chapter 178, "Fairlight FX."*

Setting Up an Ambisonic Mix

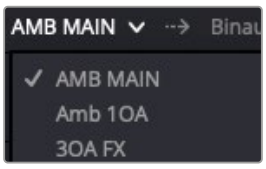
To organize and set up your Ambisonic mix:

- The first thing you need to do is determine which Ambisonic order you want to work in. A higher order such as third order (16 channels) is best for precise positioning.
- Create Ambisonic busses and assign your source tracks or other busses to them.

  You can assign Ambisonic busses to other Ambisonic busses, even with differing orders. The Fairlight engine and FlexBus will automatically handle any required up- or down-mixing.
- Use the 2D or 3D Spherical Panners on each channel to position your sources in the Ambisonic space. You can use any channel-based format from mono to stereo to, for example, 7.1.2, and position them freely in the spherical sound field.

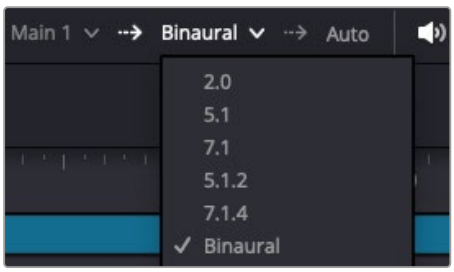
For more information on the 2D and 3D Panners, *see Chapter 174, "Mixing in the Fairlight Page."*

- Click the Bus Monitoring menu to the far right of the Transport control, and select the source you want to monitor.



Monitoring Source selection

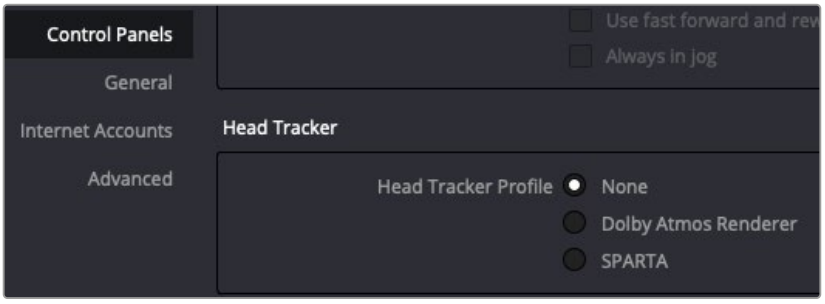
- Choose your output format in the Monitor section dropdown next to the speaker output level control. You'll notice various options, including Binaural for monitoring on headphones. Once you've selected a format, the corresponding decoder is automatically placed in the monitoring path, and the audio is routed to your Audio I/O and sent out to your speaker system.



Output Format selection

Binaural Monitoring with Head Tracking

If you've selected the Binaural option as your output format, you can also monitor your Ambisonics mix on headphones with support for Head Tracking for an enhanced monitoring experience.



Head Tracker preferences

Enabling Head Tracking

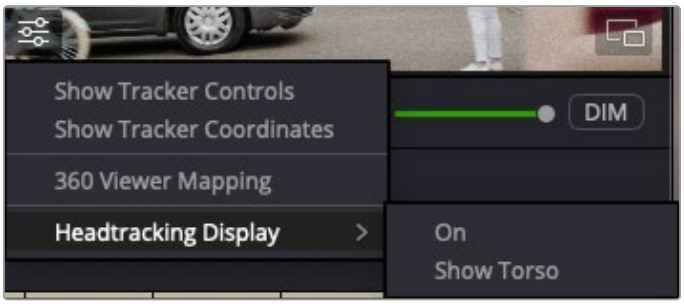
Head tracking functionality can be activated by going to Preferences > Control Panels > Head Tracker. This adds two buttons to the left of the Monitor Bus Source dropdown immediately below the docked Video Monitor panel:

- **HT:** Switches Head Tracking on and off.
- **CAL:** Calibrates the current tracker direction as the "Front" or point of origin.

Head Tracking Video Viewer Overlay

Binaural Head Tracking also lets you add an overlay to the video viewer for analyzing your mix against the picture, by clicking Headtracking Display > On, which adds an onscreen crosshair, indicating the current head (headphone) orientation.

This submenu also includes a Show Torso option which adds a head and torso to the video viewer, that rotates as the head tracking angles and positions change.



Head Tracking Video Viewer overlay

Parallel Ambisonic and Channel-based Workflows

You can create Ambisonic and channel-based mixes in the same timeline and simultaneously render multiple outputs in different formats.

Because of the common panning data, it's also possible to set up a parallel mix in an Ambisonic timeline by converting an existing production of a differing surround format (e.g., Dolby Atmos) to Ambisonics format and importing that into your production.

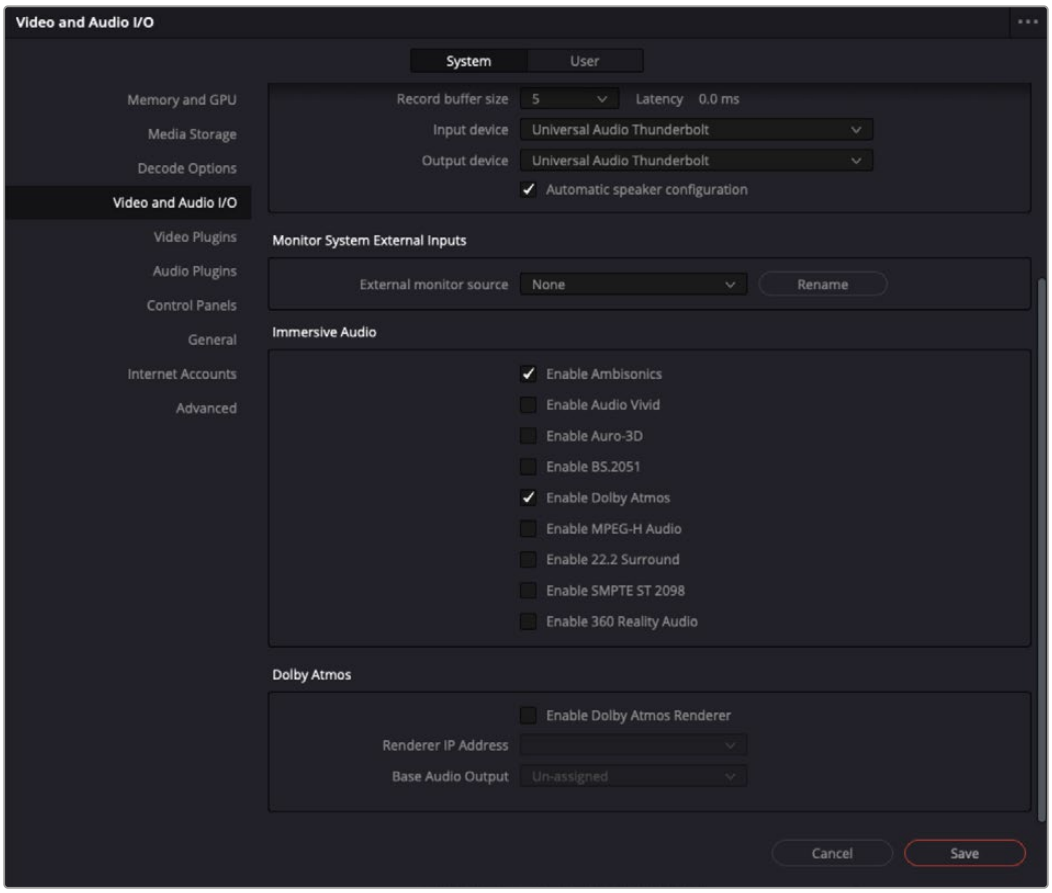
Ambisonic Rendering

Ambisonic mixes can be rendered on the Deliver page as either a multichannel adaptive file with the number of streams determined based on the Ambisonic order of the mix (e.g., 1OA, 2OA, etc.) or downmixed to the format of your choice, such as 7.1.4.

Immersive Format Configuration

In Preferences > Video and Audio I/O > Immersive Audio, you can enable the various Immersive options that are available. These are Ambisonics, Audio Vivid, Auro 3D, BS.2051, Dolby Atmos, MPEG-H Audio, 22.2 Surround, SMPTE ST 2098, and 360 Reality Audio.

In Preferences > Video and Audio I/O > Dolby Atmos, you can configure the use of an external Dolby Atmos Renderer for Dolby Atmos monitoring and mastering. You can manually enter the IP address of the server, or select a discovered server using the dropdown menu. You should also choose the base audio output of the audio outputs, which will used to send the audio to the external renderer.

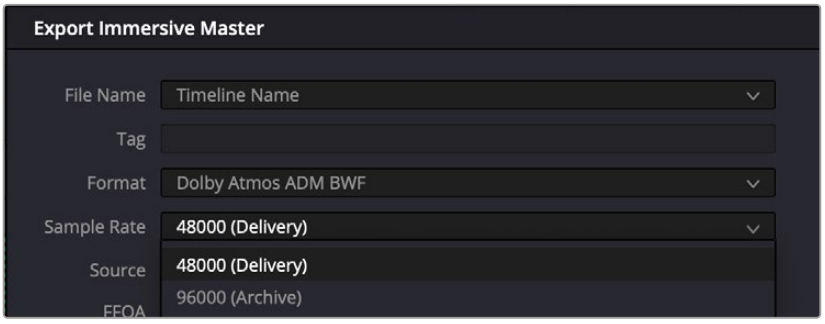


Controls for enabling immersive audio formats in the Video and Audio I/O preferences

Exporting ADM BWF

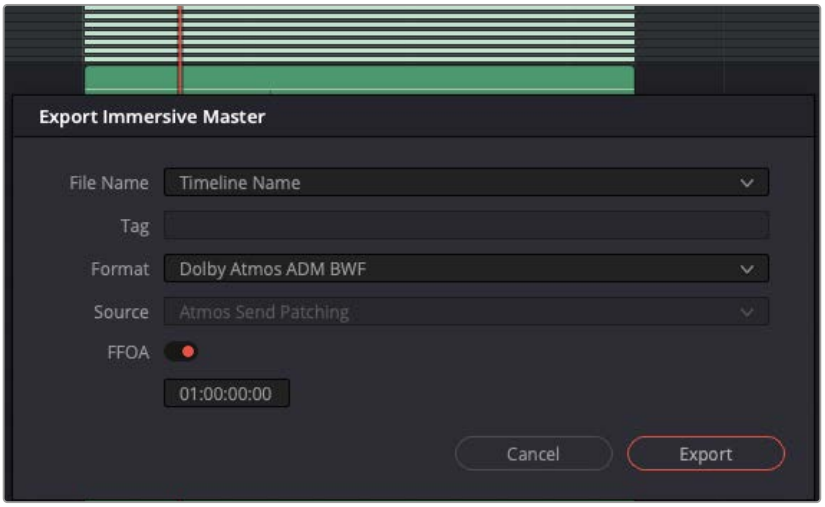
You can export a Dolby Atmos master file as an audio-only ADM BWF, right from the Fairlight timeline. These same options are also available in the Deliver page. Exporting a Dolby Atmos master file from the Fairlight timeline uses the Timeline name as the filename. Be sure to change the Timeline name to the desired filename.

- In the Media Pool, locate the current Timeline.
- Change the Timeline name to your desired export filename.
- As with all other bouncing and delivery methods, you will need to mark a range in the Timeline to export.
- Press R for the Range Selection tool. Double-click any of the Timeline clips to set a range for the entire clip.
- Choose Fairlight > Immersive Audio > Export Master File.



Export Immersive Master options

- In the Export Immersive Master dialog, set the File Name to Timeline Name and the Format to Dolby Atmos ADM BWF. You can select either 48000 (delivery) or 96000 (delivery) for the Sample Rate of the exported file. The Source is automatically set to the Atmos Send Patching. This patching passes the signal through the sends to the internal Dolby Atmos Renderer for processing and to generate a new Dolby Atmos master file.
- Click Export.
- In the Export Immersive Master finder window, navigate to the folder you want to file to save to. Click Save.



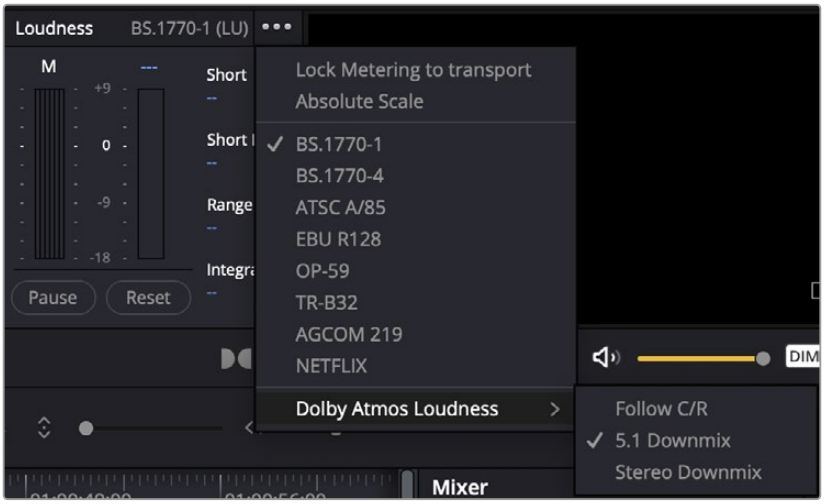
The Export Immersive Master dialog shows the source and format for the new ADM export.

The Export allows for several types of file types:

- Dolby Atmos ADM BWF
- Dolby Atmos IMF IAB
- Fraunhofer MPEG-H Production
- Fraunhofer MPEG-H Production XML

Parallel Loudness Measurement

A parallel 5.1 down-mix can be performed during the render as a source for a 5.1 loudness measurement. Certain delivery specifications (such as for Netflix) require that the loudness measurement of Atmos Masters be performed at 5.1. You can enable this parallel 5.1 (or stereo) render for the loudness measurement and monitor in the room's native format.



Selecting a Downmix option

Low-latency Rendering

Previous versions of the Dolby Atmos Renderer were able to run at a specific latency of 10.67 ms. This restriction has been removed, allowing selection of lower latency engine processing block sizes, and thus lower monitoring latency through the Dolby Atmos renderer. However, the larger block size is enforced by the renderer during certain operations, such as Binaural renderer, or when a parallel loudness down-mix is enabled.

Surround Buses in Fairlight (Studio Version Only)

The FlexBus structure in Fairlight enables user-definable buses. Atmos mixes call for several bus formats that are available in DaVinci Resolve 17 and later.

- 9.1.6
- 22.2

Object-Based Format Support (Studio Version Only)

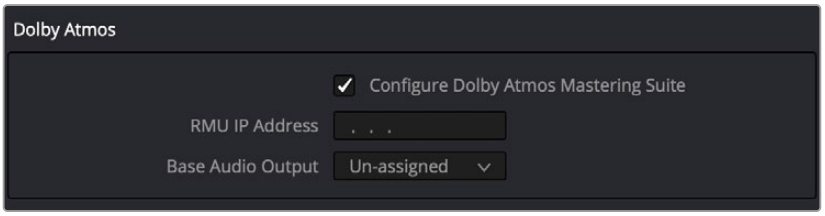
- Dolby Atmos with support for 7.1.2 and 7.1.4
- MPEG-H with support for 5.1.4, 7.1.4, and 7.2.3
- SMPTE ST.2098 with support for 9.1 OH, 9.1 HT, 11.1 HT, 13.1 HT, and 15.1 HT

Auro-3D Support (Studio Version Only)

Auro-3D with support for 9.1, 10.1, 11.1 (7+4), 13.1

Dolby Atmos Configuration Controls

The Video and Audio I/O panel of the Resolve System Preferences lets you enable and configure the use of a Dolby RMU for doing Dolby Atmos mixing. You can enter the IP address of the RMU, and choose the base audio output.

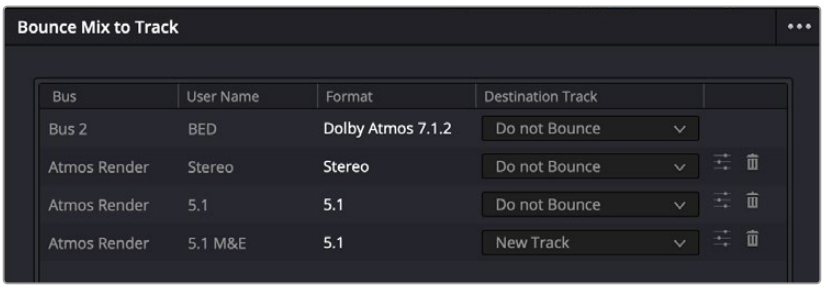


Configuring Dolby Atmos in the Resolve System Preferences

Atmos Re-Renders

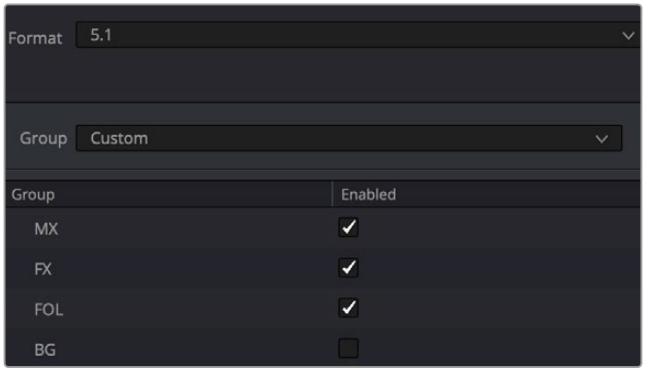
In order to provide parity with the external renderer, you can create presets that let you define a PCM output format and a set of sources using the bed, object, and group definitions (such as 5.1).

Bounce Mix to Track accommodate these re-render presets in Dolby Atmos timelines, allowing you to generate multiple deliverables in a single pass. These render presets are stored and recalled as part of the timeline.



Bounce Mix to Track Dolby Atmos re-render options

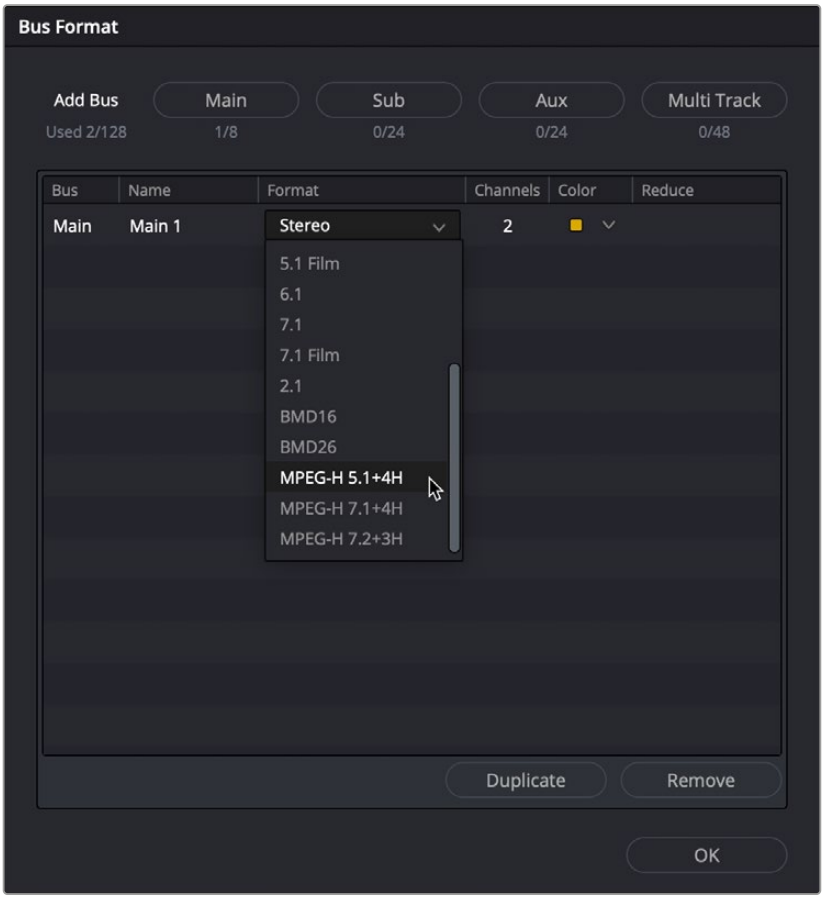
In addition to render format, you can select the source from a combination of beds, objects, or defined VCA groups.



Dolby Atmos Render Preset options

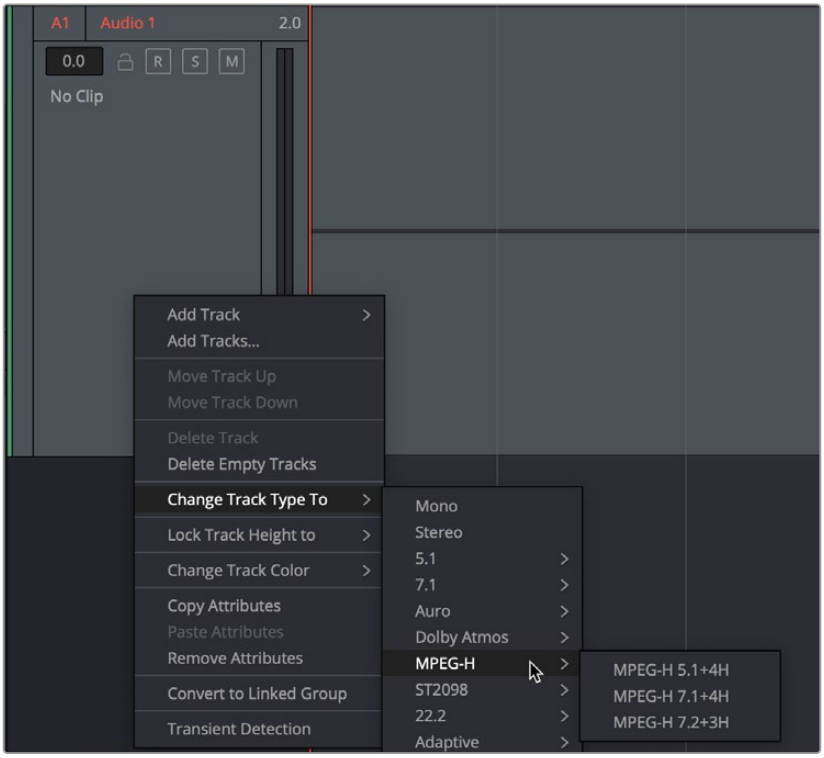
MPEG-H Authoring

DaVinci Resolve enables MPEG-H authoring. This includes Native MPEG-H track and bus formats and monitoring, including the ability to define basic track-level meta-data for export into an MPEG- H scene, and export of a MPEG-H Master file. Once enabled, the formats become available for selection as a bus, track, or monitoring format, in the Bus Format window.



The MPEG-H format options in the Bus Format window

These formats also become available for multi-channel track assignment.



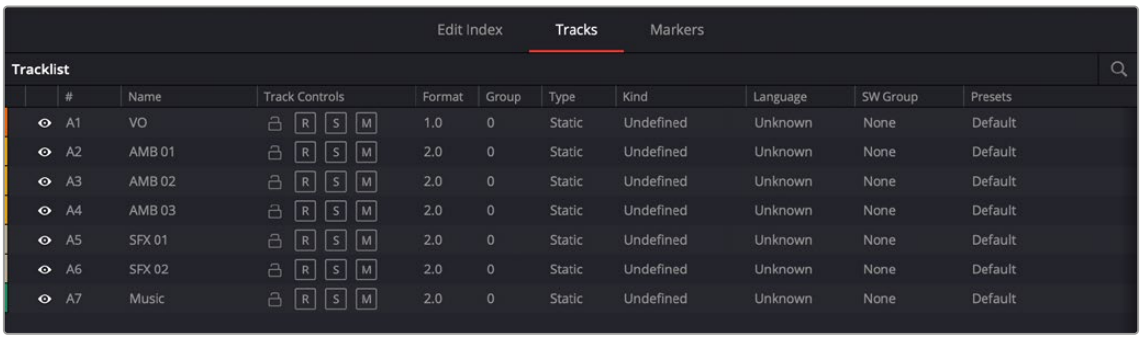
The MPEG-H format options in the Track Format submenu

Tracks are mixed natively in a similar manner to most immersive content, with the creation of a bed mix consisting of a set of immersive object tracks that use dynamic panning. These are combined onto the main bus to form the immersive mix.

Track Configuration

In addition to this process, once the format is enabled, a set of MPEG-H meta-data columns become enabled in the DaVinci Resolve Track index, including Track Type, Kind, Language, SW Group, and Preset.

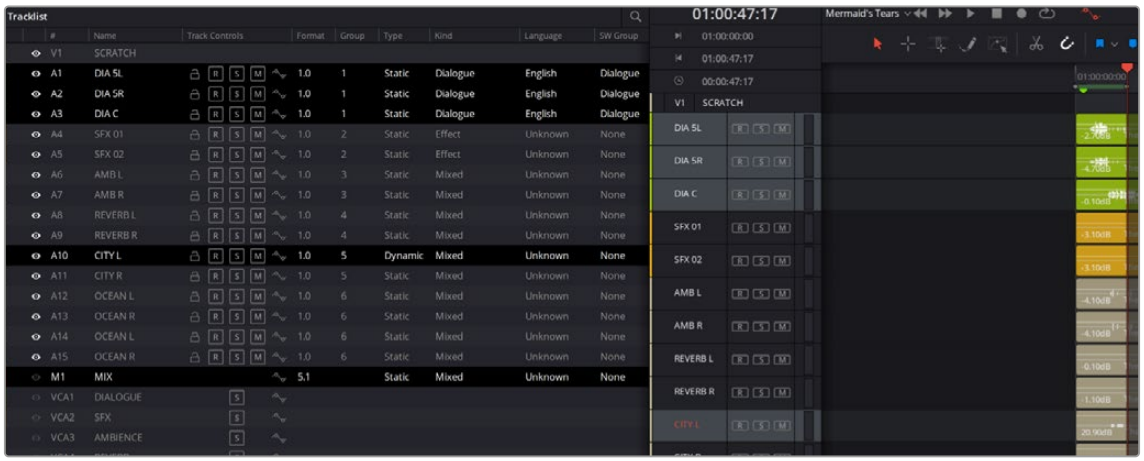
> For more information about these columns and how to configure them, *see Chapter 167, "Using the Fairlight Page."*



When MPEG-H is enabled in the Project Settings, the Tracks panel shows additional columns of information for defining each track in the Timeline

Export

Once everything is configured, and your project is mixed, you export a master file. In order to do this, you must select a range In and Out point on the Timeline to define an export range. Additionally, you must define whichever busses are designated for rendering by defining their Kind, and you can select tracks you want to export additionally.



Selecting tracks and busses to export

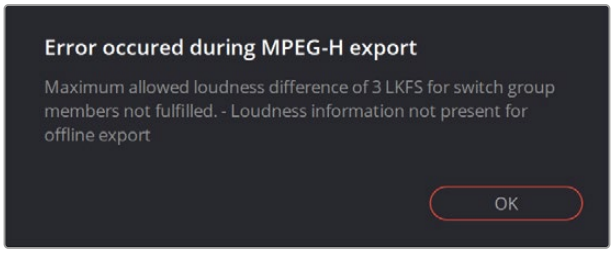
> **NOTE:** An MPEG-H master file can only contain a maximum of fifteen channels total. If the selected track and bus stems exceeds this, then the export will fail, issuing a warning. The same will occur if a range is not selected.

To export an MPEG-H mix:

1. Choose Fairlight > Immersive Audio > Generate MPEG-H Audio File.
2. Choose a save location and name, and click Save.

At this point, all defined buses are rendered. Then, track loudness is measured for compliance. Lastly, the source audio is exported and the metadata embedded into the deliverable MPEG-H wav file.

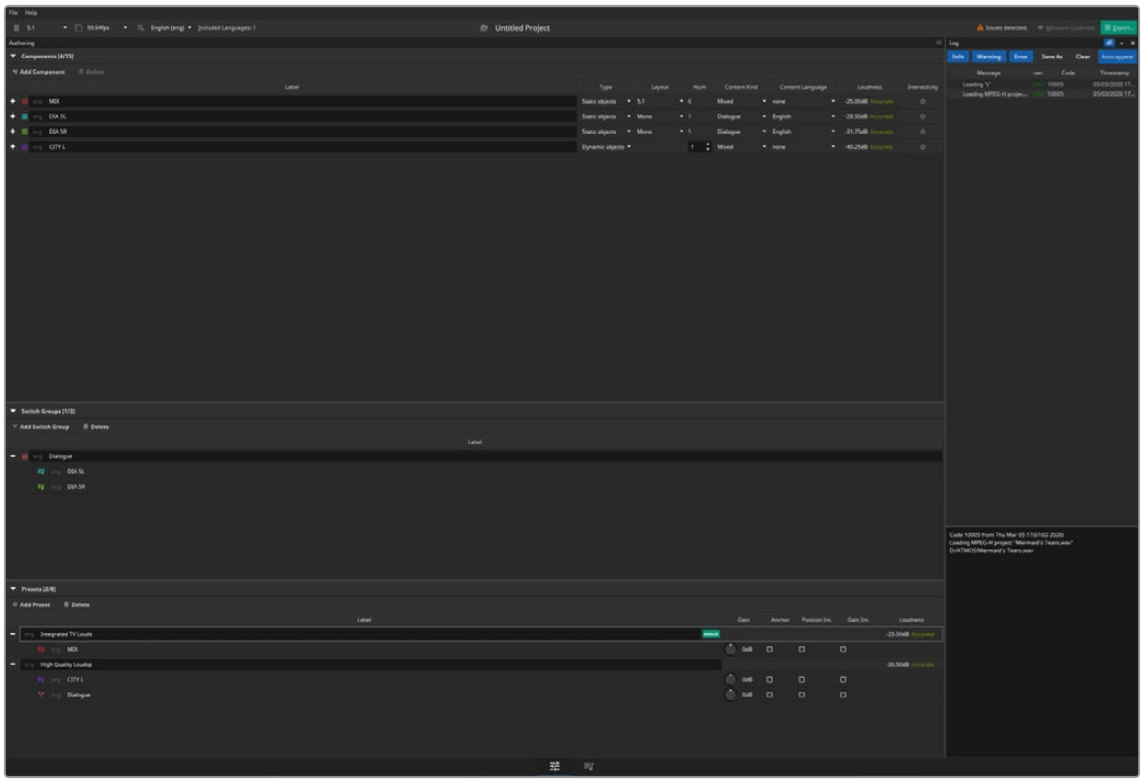
There are several error conditions, which are deleted during the export process, that will all cause the export to fail. For example, all tracks must contain audio. Audio within switch groups must be within a specific loudness tolerance of one another. If any of these conditions occur, a dialog will appear.



Warning dialog during MPEG-H export

Quality Control

You can do a quality control check of the final audio export using a Fraunhofer MHAPI tool which can open up the exported content. This includes compliancy tests, and visualization of the contained metadata. It can also render and monitor the content, but this aspect of the tool is basic, and only works with external audio that's linked to the metadata. In other words, you must manually link the components back to the source audio files.



Quality control using the Fraunhofer MHAPI tool

B-Chain Support for Audio Monitoring (Studio Version Only)

Choosing Fairlight > Immersive Audio > B-Chain Control opens the B-Chain Control window. Using traditional cinema audio postproduction terminology, the "A-Chain" is all of the busing and signal processing that happens within the mix (in our case using the Fairlight page) and the "B-Chain" is the signal processing, amplification and speaker system that takes the sound from your workstation's output and gets it "into your ears." This typically includes all necessary signal decoding or pre-processing hardware, amplification systems, and speaker setups for most professional and commercial listening environments, especially for immersive audio or surround sound formats. These options are complex and have many variables in terms of speaker configuration, selection, and placement, output channel timing, attenuation, and phase, and a host of other considerations.

In DaVinci Resolve, these B-Chain controls affect how the channels of audio being output by the Main you're mixing is mapped to the actual audio signals being output from your workstation into the amplification and speaker system of the current viewing environment. The extensive level of control the B-Chain presets offer is most useful in situations such as surround-sound configured grading and mixing theaters, to define how the immersive audio standard you're mixing is mapped to

the speaker setup of your particular application, and to fine-tune the channels being output to each speaker specifically for your environment. In simpler monitoring situations, the B-Chain controls can be useful for configuring the standard you're mixing with to play out of a non-standard speaker setup in your room.

Ultimately, the B-Chain controls are designed and intended for users who need to create custom, fine-tuned settings for their specific monitoring situation. For this reason, pretty much every real-world use of these B-Chain controls will require custom configuration for your unique environment.

Overview of Setting Up a B-Chain Configuration

Setting up a B-Chain configuration takes some doing, but once set up, you have a preset that's easy to reopen at any time. In the following example, a B-Chain preset will be configured to convert a 5.1 surround output to a 3-channel left-center-right room speaker setup.

To set up a B-Chain:

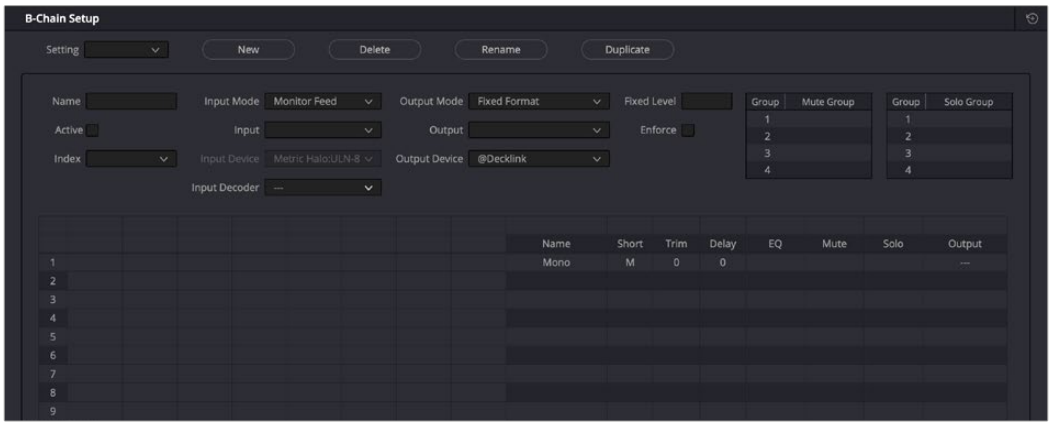
1. Choose Fairlight > Immersive Audio > B-Chain Control to open the B-Chain Control dialog. This exposes the monitoring controls but not the configuration controls.
2. Click the Option menu in this window and choose Setup B-Chain Presets. The B-Chain Setup window appears.
3. Click the New button to create a new B-Chain preset, then enter a name in the dialog and click OK. In this example we'll use the name "5.1 to LCR." The Name you enter here is the name of the saved setting data.

   Additional buttons let you Delete, Rename, or Duplicate presets that you've already created once you choose them from the Setting pop-up.
4. Enter a label in the Name field (this is the name that appears in the preset menu). The name you enter here is the name that appears in whatever pop-up menus you select these options from.
5. Choose Input Mode > Fixed Format, and Input > 5.1 from the pop-up menus. These define the signal coming out of your mix. (Input Mode > Monitor Feed sets the B-Chain to listen to the selected monitor source, while Input Mode > Custom Format lets you choose an arbitrary number of channels.)
6. Choose an Output Mode > Fixed Format, and Output > LCR from the next set of pop-up menus. These define the speaker setup you'll be playing the mix out of. In this example, we've chosen LCR, which stands for Left, Center, Right.

   At this point, you can see that once you've defined the Input and Output channels, the "Inputs/Outputs" table of cells becomes populated:

   - At the left of this table, each channel of your selected Input occupies a vertical column. In this example, the Input columns are labeled L, R, C, LFE, Ls, Rs, corresponding to the 5.1 channels you've selected to be output. It's possible to specify setups with many more channels, in which case the left half of the table becomes scrollable.
   - At the right of this table, each channel of your selected Output occupies a horizontal row that intersects the Input columns. In this example, the rows are labeled Left, Center, Right.

   In this way, every Input column intersects with each Output row, making it possible for you to assign how much of each Input is fed to each Output by entering values into each intersecting cell.



The Inputs/Outputs table of the B-Chain preset window

7 To assign Input channels to Output channels, double-click the field where the desired Input intersects the desired Output, and type a value to set how much level from the Input to assign to the Output. Typing 0 assigns Input to Output at “unity” gain (0dB). Numbers you type here specify tenths of a dB. Typing -3 assigns half of the level from Input to Output. Typing -100 mutes that Input to that Output completely. Blank cells with no value make no assignment. In this example, we’re typing:

- **a)** 0 into cell L-1 to assign all of the Left source to the Left output
- **b)** 0 into R-3 to assign all of the Right source to the Right output
- **c)** 0 into C-2 to assign all of the Center source to the Center output
- **d)** -6 into Ls-1 to assign a fraction of Left surround to the Left output
- **e)** -6 into Rs-3 to assign a fraction of Right surround to the Right output
- **f)** -8 into LFE-1 to assign a smaller fraction of LFE to the Left output (LFE is not directional)
- **g)** 8 into LFE-3 to assign a smaller fraction of LFE to the Right output as well (LFE is not directional)

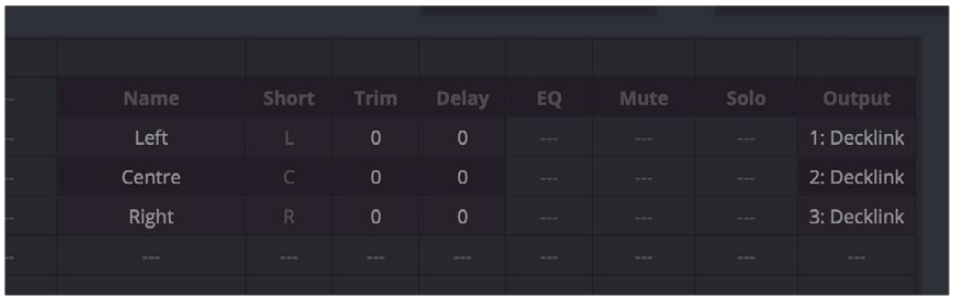
At this point, we’ve fully defined how much of which Input channels go to which Output channels. In the process, you can see that this table interface makes it possible to assign the full levels of Input channels to Output channels, to assign partial levels of Input channels to Output channels, and to assign fractions of Input channels to multiple Output channels.

The Inputs/Outputs table of the B-Chain preset window fully populated to assign inputs to outputs

8 At this point, you should notice there are additional columns to the right of the Output channels that provide various options that let you fine-tune each channel’s output in order to optimize the acoustics and layout of your room:

- Trim each channel (in tenths of a dB)
- Add a Delay (in milliseconds)
- Add specific EQ (None, LFE Only, Surr Mode)
- Mute or Solo groups.

9 The last thing you need to do is to right-click each Output channel row's right-most Output column, and choose the hardware output of your audio or video+audio interface that you want that channel to go to. See one of the following I/O Setup procedure for how to rename these options to make this easier.



Assigning I/O channels to output to

Once you've finished setting up your B-Chain preset, click OK, and that preset will be saved and available for use.

To choose a B-Chain preset to use and enable B-Chain:

1 Choose Fairlight > Immersive Audio > B-Chain Control to open the B-Chain Control dialog.

2 Turn on the toggle at the upper left-hand corner of the window to enable B-Chain, and choose a preset from the pop-up menu.

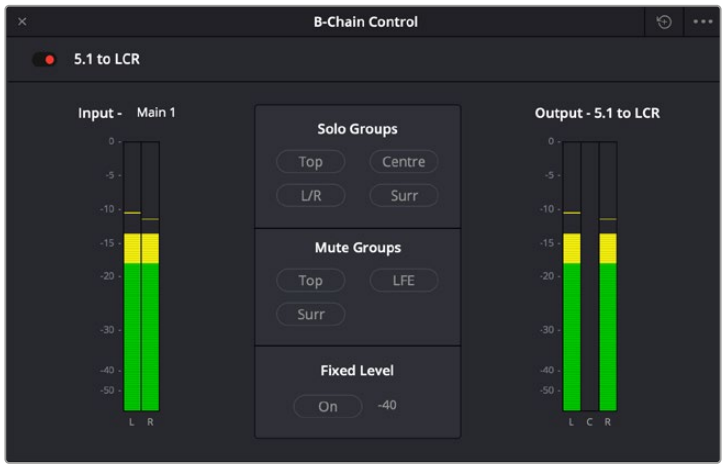
3 Choose the Input you want to assign that B-Chain preset to.

4 A set of Solo and Mute buttons lets you selectively choose sets of channels you want to listen to in isolation, or mute from the whole, in order to better evaluate selected portions of your mix.

5 A Fixed Level button lets you fix the output level in the DaVinci Resolve UI to a single value. With this enabled, you cannot drag the level slider to change the monitoring volume.

6 When you're finished using B-Chain for monitoring, turn off the toggle at the upper left-hand corner.

NOTE: While the B-Chain is enabled, the Speaker Setup controls in the Video and Audio I/O panel of the Resolve System Preferences is disabled.

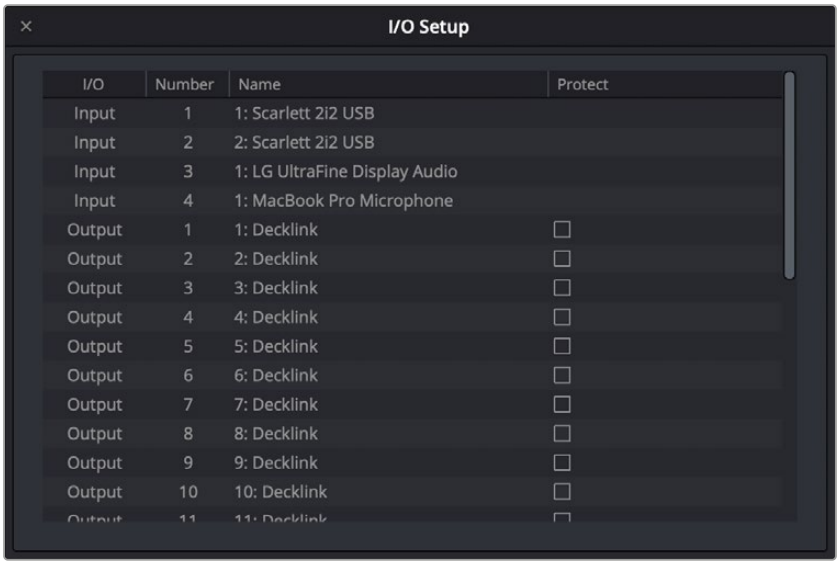


The B-Chain Control Window where you can choose and enable a B-Chain preset to affect the output

To name the various outputs of your system's channels for easy assignment:

1. Choose Fairlight > Immersive Audio > B-Chain Control to open the B-Chain Control dialog.
2. Click the Option menu in this window and choose Setup I/O Names. The I/O setup window appears, showing every single audio input and output on every audio interface that's connected to and recognized by your system.

   The I/O Setup window lets you rename the Inputs and Outputs associated with your workstation setup, to make it easier to configure Fairlight when you're managing hundreds of channels. The names you choose here are shown everywhere in DaVinci Resolve where channels are selectable and/or exposed.
3. To rename a channel, double-click that channel's field in the Name column, type a new name, and press Return.
4. To protect a channel, click the checkbox in the Protect column. Protected channels are prevented from being patched to. This is intended for potentially high-volume speaker outputs, to which it would be hazardous to accidentally connect the wrong input. Protected channels can be seen everywhere patches can be made, but they're grayed out. Protected channels can only be used in the Speaker Setup controls in the Video and Audio I/O panel of the Resolve System Preferences, and in the B-Chain Setup window.
5. When you're finished, close the window. The names and protected status of channels are a system-wide setup.



The I/O Setup window where you can rename your system's audio outputs and protect channels going to amplified speakers

Space View

Space View is a 3D interactive workspace that lets you view your unmuted sound sources' real-time positions and automated movements.

You can freely reposition sources in the 3D sound field according to your mouse movements (Left/Right and Forward/Backward). Holding down Command while moving your mouse forward and backward moves the sound source up and down in the sound field. All your changes can be automated (Touch and Pan) and saved.

Space View can be opened by going to Fairlight > Immersive and selecting Space View.

NOTE: Only unmuted sources with a fader level greater than -70dB will be visible.

Space View of an Immersive mix

Space View Controls

The Space View offers the following control options, which, when used in conjunction with the track mute and solo buttons offer very flexible options that let you focus on individual sources or groups of sources.

In the lower right corner of the workspace, you'll find four buttons that let you view your sound sources from different angles or perspectives.

You can freely rotate the workspace by holding down Command-Option-Shift while dragging it. If you want to get back to a default view, click one of the perspective buttons.

Along the lower edge of the window, you'll find the following checkboxes:

- **Ambisonics Metering:** This checkbox activates Ambisonics sonar-type metering when working on Ambisonic mixes.
- **Compact Meters:** This option replaces the larger halo-style meters with smaller bar-graphs.
- **Show Active Level Only:** Clicking this option hides the names of silent sound sources.
- **Show Beds:** This option reveals the labels and meters for sound sources that are part of sound beds instead of just the signals feeding your master Dolby Atmos bus.

The options in the dropdown menu to the right of the checkboxes determine which objects appear in the virtual space:

- **Show Only Selected:** Shows sources based on tracks you've selected in the Mixer or timeline.
- **Show Visible:** Shows only the active audio sources for tracks that are not hidden.
- **Show All:** All sound sources are visible and labeled.

Delivery Effects Processing

For your final output, how effects are rendered depends on whether you're rendering in Single Clip or Individual Clips mode.

When Rendering a Single Clip or When Outputting to Tape

Whether you're rendering a QuickTime or MXF master of your project as a single clip, rendering a DPX image sequence for film output, or outputting directly to tape, all supported compositing, speed, and transform effects are rendered by DaVinci Resolve and "baked" into the output media. Unsupported effects are completely ignored, cannot be seen, and have no effect on media that's rendered and output.

When Rendering Individual Source Clips for Round-Trip Workflows

In workflows where you're rendering individual media files to send a project back to an NLE or finishing application for final finishing (adding titles and other effects before final delivery), DaVinci Resolve handles different types of effects in different ways.

Unsupported effects do not appear in DaVinci Resolve. However, this effects data is internally preserved, and when you export an XML or AAF file to send back to your NLE of choice, these effects reappear, applied to the color corrected media that you rendered out of DaVinci Resolve and sent back.

Effects that DaVinci Resolve does support such as composite modes, opacity settings, speed effects, and transitions are handled differently. Even though these effects are visible in DaVinci Resolve while you work, they're not "baked" into the final media that you render in preparation for sending back to your NLE or finishing application. Instead, the portion of each media clip that's used in your project is rendered as an individual file, and the XML file that you export from DaVinci Resolve contains all of the effects information necessary to reassemble the rendered media into a timeline that uses Final Cut Pro effects applied to DaVinci Resolve-graded media.

	EDL	FCP 7	FCP X	Premiere Pro	Media Composer*
Color Corrections	N/A	N/A	Rendered	N/A	N/A
Composite Modes	N/A	Sent Back	Sent Back	Sent Back	Rendered
Alpha Channels	N/A	Optionally Rendered	Optionally Rendered	Optionally Rendered	Optionally Rendered
Transitions	Sent Back	Sent Back	Sent Back	Sent Back	Sent Back
Opacity Settings	N/A	Sent Back	Sent Back	Sent Back	Sent Back
Position, Scale, Rotation	N/A	Conditional	Conditional	Conditional	Conditional
Linear Speed Effects	Sent Back	Sent Back	Sent Back	Sent Back	Sent Back
Variable Speed Effects	N/A	Sent Back	Sent Back	Sent Back	Sent Back
Long Duration Still Images	N/A	N/A	N/A	N/A	N/A
Freeze Frames	N/A	N/A	N/A	N/A	Rendered

* These effects are only sent back in AAF round trips when you're updating an existing AAF file, rather than generating a new AAF file.

The chart shows which effects are rendered by DaVinci Resolve, and which effects are passed back in different round trip workflows.

After you've reimported your project back into your NLE or finishing application, you're free to readjust these effects while completing your program, without the need to re-render individual clips in DaVinci Resolve.

IMPORTANT: One exception to the preservation of media and effects in round-trip workflows is that nested sequences from Final Cut Pro 7 and Media Composer are not compatible with DaVinci Resolve; XML and AAF files containing nested sequences cannot be imported. On the other hand, Final Cut Pro X projects containing compound clips can be imported.

More About Rendering Speed Effects

If you're rendering a project with speed effects, you should be aware that DaVInci Resolve can optionally render speed effects using Optical Flow processing, resulting in high-quality slow motion and fast motion effects delivered straight out of DaVinci Resolve. If you're satisfied with Optical Flow processing in DaVinci Resolve, there may be no need for you to do a round-trip export if the main reason you were doing so was to send the processing of slow motion clips to another application for rendering, and rendering the Timeline in Single clip mode will "bake" the speed effects in using whatever settings you've selected for the project, or for each clip if you've selected individual Retime Process settings for different clips.

However, if you want to send unrendered speed effects to another application, rendering your project in Individual source clips mode guarantees that the full range of each original clip of media will be rendered, with the speed effect itself exported within the XML, AAF, or EDL file that's exported.

NOTE: DaVinci Resolve adds three frame handles to clips with speed changes applied to them, and to rendered clips that don't match the project's frame rate. This is done to facilitate reconform in NLEs that require handles beyond the actual length of each of these clips.

Determining the Rendered Output Resolution of Clips in Mixed Timelines

Ordinarily, rendering individual source clips results in each clip being rendered at either the project resolution or the Resolution dropdown in the Render Settings (which overrides the project resolution), with clips that don't match the project resolution being resized or not according to the settings you've chosen in the Image Scaling panel of the Project Settings.

However, if you're rendering dailies for projects containing clips with mixed resolutions, you can choose to render each clip at its original resolution by turning on the "Render at source resolution" checkbox in the Video group of controls.

Rendering Edit and Input Sizing Adjustments

Whether or not sizing is rendered into your final media depends on the “Disable sizing and blanking” checkbox in the Advanced Settings options of the Render Settings panel. You can disable sizing and blanking either when rendering the current Timeline as a single clip, or when rendering individual clips.

- **If “Disable sizing and blanking output” is turned off:** Output Blanking, Cut and Edit page sizing adjustments, Color page Input and Output Sizing adjustments, and Image Stabilization are rendered into the final rendered media using the optical-quality sizing algorithms available to DaVinci Resolve. This is best if your sizing adjustments are approved and final, and you want to “bake” sizing adjustments into the final media you’re delivering.
- **If “Disable sizing and blanking output” is turned on:** Output Blanking, Cut and Edit page sizing adjustments, Color page Input and Output Sizing adjustments, and Image Stabilization are not rendered, and each clip will be rendered either at the source resolution if “Render at source resolution” is enabled in individual clips mode, or to the currently specified resolution of the Timeline or project. However, the sizing adjustments you’ve made will be exported as part of the XML or AAF file that you’re exporting. This is best for workflows where the editor wants to continue adjusting sizing after you’ve handed off the graded project relative to the original size of the clips.

Keep in mind that if you want to render Input Sizing adjustments into the media you’re outputting, the “Force sizing to highest quality” checkbox guarantees that DaVinci Resolve will use the highest-quality sizing setting, even if you’ve temporarily chosen a faster-processing option for a slower computer.

> **NOTE:** “Disable sizing and blanking output” does not disable any transform operations that happen within the Fusion page, nor does it disable transforms happening as a result of an Open FX or Resolve FX plugin applied to one or more clips in the Cut, Edit, or Color pages. All of these effects will continue to be rendered into the final output.

Rendering Mixed Frame Rate Timelines

Mixed frame rates are supported by DaVinci Resolve when any option other then none is selected in the “Mixed Frame Rate format” dropdown menu, either in the Conform Options section of the General Options panel of the Project Settings, or in the Import AAF or XML dialog. When you choose the appropriate option that corresponds to the application you’re exchanging projects with (or DaVinci Resolve if you’re working entirely within DaVinci Resolve), then DaVinci Resolve conforms and processes all clips in the Timeline to play at whichever frame rate is selected in the “Timeline frame rate” dropdown menu. For example, 23.98, 29.97, 30, 50, 59.94, and 60 fps clips will all play at 24 fps if that’s what “Timeline frame rate” is set to in the Master Settings panel of the Project Settings.

How clips in mixed frame rate timelines are rendered out depends on whether the Render Settings are set to render Individual source clips or a Single clip.

- **Individual source clips:** All clips are rendered individually at their original frame rate.
- **Single clip:** All clips are converted to the “Timecode calculated at” frame rate and rendered as a single media file. Clips are converted using whatever method is selected in the Retime process dropdown of the Master Settings panel of the Project Settings, or in the individual Retime process setting found in the Video inspector of each clip that overrides the project-wide setting. You can choose Optical Flow processing for the highest quality conversion that’s available in DaVinci Resolve.

Export Alpha Channels in Individual Clips Mode

This option only appears if you're rendering to a media format that supports alpha channels. If your media contains an Alpha channel, you have the option to turn on the Export Alpha checkbox in the Video panel of the render settings whenever you render individual source clips. When you do so, DaVinci Resolve renders clips with alpha channels in either of two cases:

- Whenever there is an Alpha channel embedded in the source media for that clip, the embedded Alpha channel will be copied to the rendered version of that clip.
- Whenever a clip's grade has a key connected to an Alpha output, the Alpha output will be rendered as an Alpha channel for that clip.

In either case, you may only render Alpha channels out when you render individual source clips to an RGBA format such as TIFF, OpenEXR, ProRes 4444, ProRes 4444 XQ, or DNxHR 444.

Export Alpha Channels in Single Clip Mode

DaVinci Resolve allows rendering Alpha channels in Single Clip mode if the selected codec supports an Alpha channel (i.e., ProRes 4444, DNxHR 444, etc.). This lets you apply a single Alpha channel to an entire timeline for export, rather than just at the individual clip level.

To Render an Alpha Channel in Single Clip Mode:

1. Select "Single Clip" mode in the Render Settings.
2. Select a codec that supports an Alpha channel in the Video tab's Codec and Type selection boxes.
3. Select the checkbox "Export Alpha" that appears under the Frame rate selector.
4. If supported by the codec, you can chose the Alpha Mode type. Premultiplied is the default.

If the codec you have selected does not support an Alpha channel, the "Export Alpha" box will not appear as an option.

Chapter 183

Using the Deliver Page

Once you've finished grading your project, you need to either render it, or output it to tape to deliver it to your client. This is where the Quick Export window and Deliver page comes in.

This chapter describes how to use Quick Export, how to use the overall interface of the Deliver page, and provides some general information about how effects are output from DaVinci Resolve in different situations.

Contents

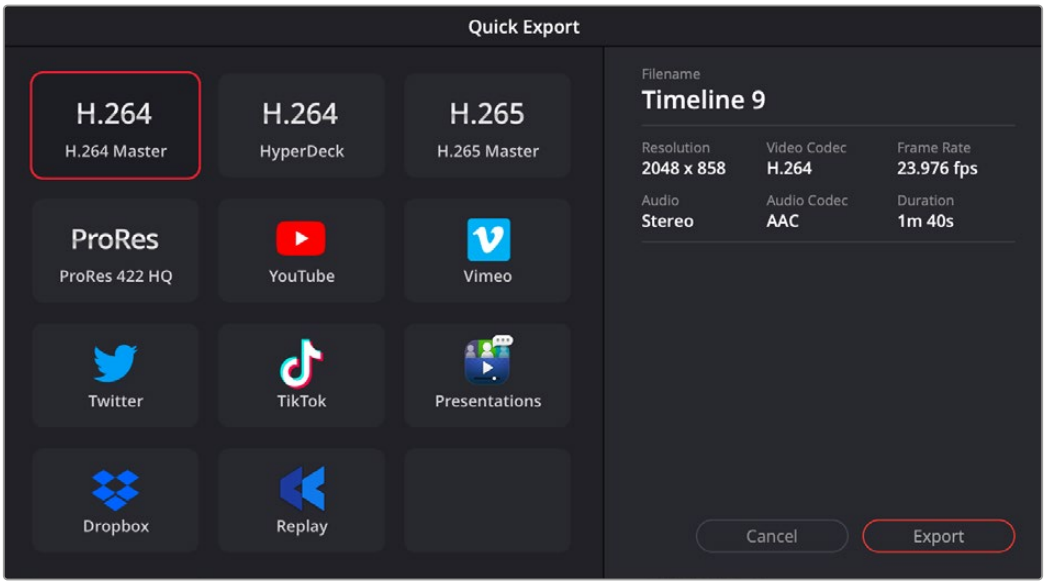
Using Quick Export 3845
The Deliver Page 3846
The Interface Toolbar 3846
Rendering Files vs. Outputting to Tape 3847
The Render Settings 3847
The Deliver Page Timeline 3848
Filtering the Thumbnail Timeline 3849
The Viewer 3850
Disabling Viewer Updates While Rendering 3850
The Render Queue 3851
Drag to Reorder Jobs in the Render Queue 3852

Using Quick Export

Not every situation requires a complicated delivery setup. When you just need to quickly export a project, and the full power of the Deliver page is unneeded, you can choose File > Quick Export to use one of a variety of export presets to export your program from any page of DaVinci Resolve. You can even use Quick Export to export and upload your program to one of the supported video sharing services, including YouTube, Vimeo, and Frame.io. You can also add your own presets to the Quick Export window.

To use Quick Export:

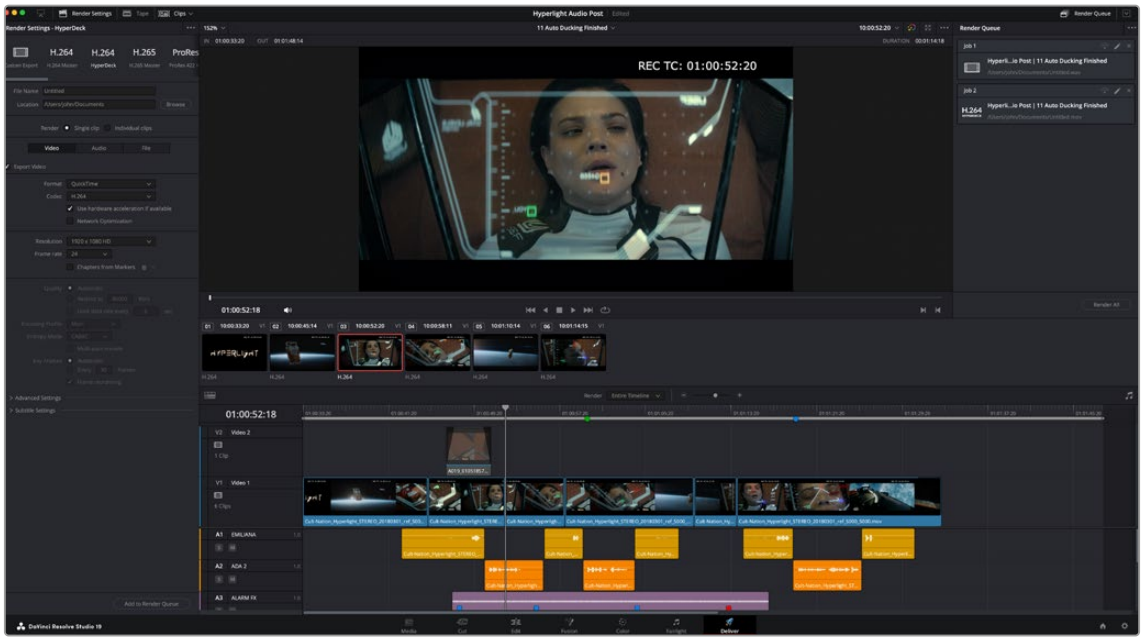
1. (Optional) In the Cut, Edit, Fusion, or Color page, set In and Out points in the Timeline to choose a range of the current program to export. If no timeline In or Out points have been set, the entire timeline will be exported.
2. Choose File > Quick Export.
3. Select a preset to use from the top row of icons in the Quick Export dialog, and click Export.
4. Choose a directory location and enter a file name using the export dialog, then click Save. A progress bar dialog appears to let you know how long the export will take.



The Quick Export dialog

The Deliver Page

The Deliver page is divided into five areas of functionality, each of which lets you set up a different part of a render or output to tape.



Deliver page

The Interface Toolbar

At the very top of the Deliver page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

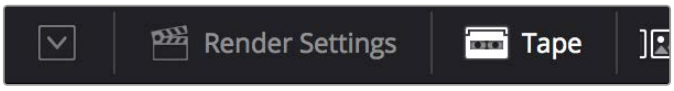
The Interface toolbar

	Delivery full/half height button: Lets you set the Render Settings panel to take up the full height of your display, if you need more area for browsing the various render settings, at the expense of a narrower Timeline.
	Render Settings: This panel lists all of the render settings that are available for configuring rendering jobs in DaVinci Resolve. By default, you're presented with a short list, but more options are available by clicking "Advanced Settings."
	Tape: Puts the Deliver page into Tape Output mode.
	Clips: Hides or shows the Thumbnail timeline above the Deliver page timeline

	Render Queue: A list of all jobs that you've set up to render in the current project. Previously rendered jobs remain in the queue, for your reference or for you to reuse to re-render those jobs, unless you manually delete them from the queue.
	Render Queue full/half height button: Lets you set the Render Queue to take up the full height of your display, if you need more area for listing render jobs at the expense of a narrower Timeline.

Rendering Files vs. Outputting to Tape

Because the Deliver page does double duty, you control whether you're rendering files or outputting to tape using the Tape button in the Interface toolbar. Doing so replaces the controls in the Viewer with tape controls.



Render or Edit to Tape modes

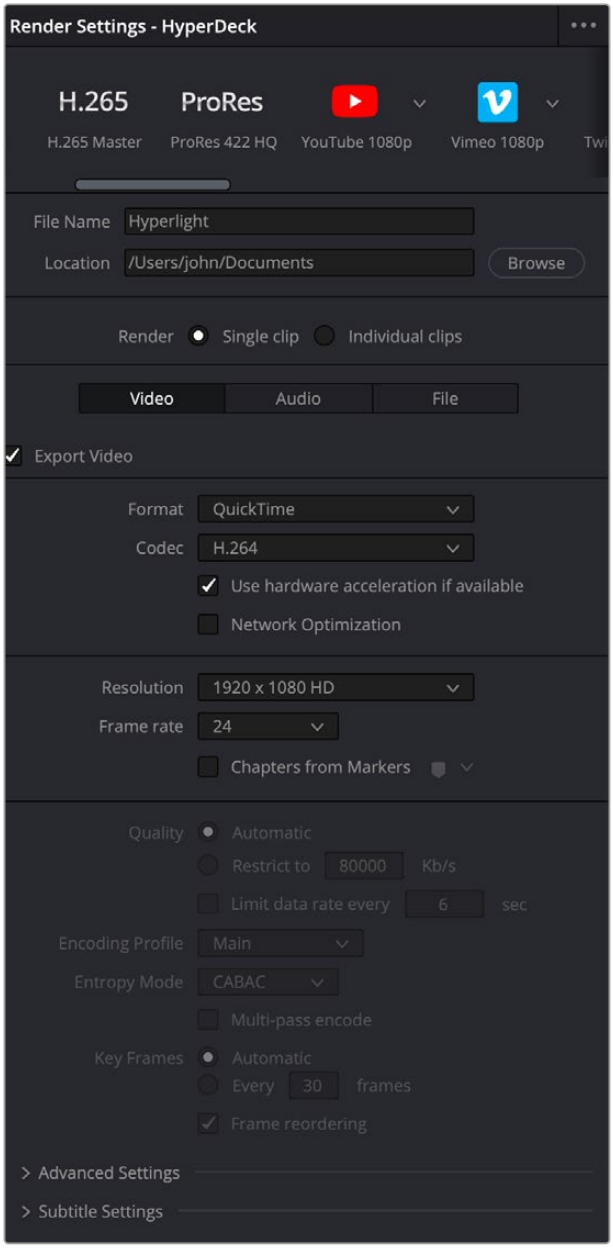
The Render Settings

The Render Settings contains the customizable settings that determine how media is rendered out of DaVinci Resolve. If you're using the Tape option, these settings are disabled.

The Render Settings are divided into four general sections:

- **Render Presets:** At the very top, a scrollable row of icons lets you choose one of a series of presets to quickly set up the type of render you want. The Custom option exposes all render settings so you can set up a render manually.
- **Render Location:** A Browse button opens a dialog that lets you choose a volume and directory to render to.
- **Render:** Two options let you either render the entire selected area of the Timeline as a single clip suitable for reviewing or mastering, or as a series of individual clips more suited to round-trip workflows. The option you choose here changes which render settings are available below.
- **Video, Audio, and File Render Settings Panels:** All other render settings are divided among three panels. Checkboxes at the top of the Video and Audio panels let you selectively disable video export (if you want to export the audio only) or disable audio export (if you want to export video only).

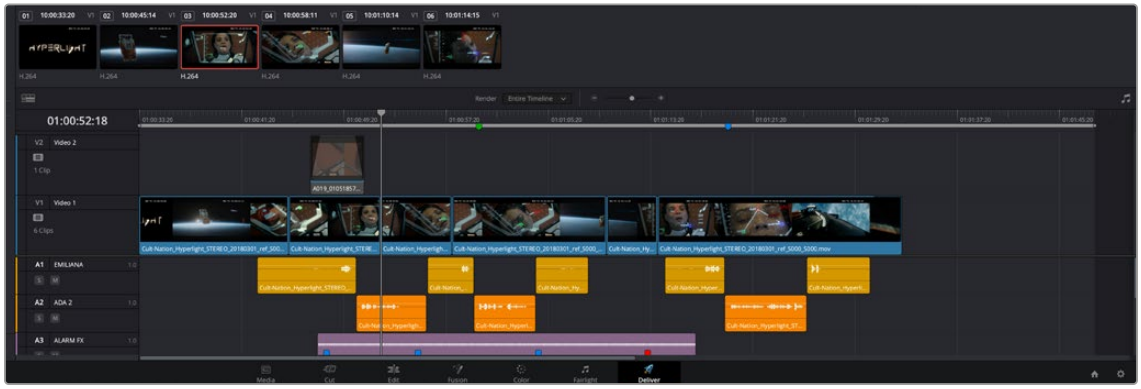
For more information on all of these settings, *see Chapter 184, "Rendering Media."*



Render Settings

The Deliver Page Timeline

You'll use the Timeline in the Deliver page to define the range of clips you want to render or output to tape, and to choose which versions for each clip you want to output. The Deliver page Timeline consists of a Thumbnail timeline at top (that can be shown or hidden via the Clips button) that makes it easy to select individual clips or ranges of clips that you need to render, and a more ordinary timeline below that you can use to set In and Out points for rendering arbitrary regions of your program.
A Timeline toolbar lets you choose the render range of the Timeline, and has controls for customizing the look of the Timeline, and for zooming in and out.

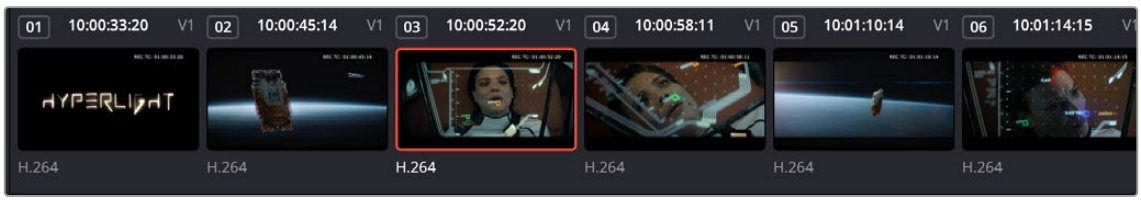


The Deliver page's Timeline and Thumbnail timeline

TIP: Press Shift-Z to fit the entire program into the available width of the Timeline.

Filtering the Thumbnail Timeline

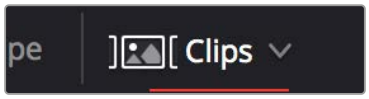
The Deliver page Thumbnail timeline also has the Timeline Filter dropdown, available to the right of the Clips button in the Interface toolbar.



The Deliver page's Thumbnail timeline matches the Color page

Using this dropdown to filter the contents of the Timeline lets you restrict the range of media you want to output in different ways. For example, if you've already rendered a timeline, but you've since made some changes, you can use one of the "Modified Clips" options to display only the clips that have changed within a particular timeframe. Another commonly used option is to choose "Unrendered Clips" to isolate all clips that have not yet been rendered in workflows where you're only rendering a part of the Timeline at a time.

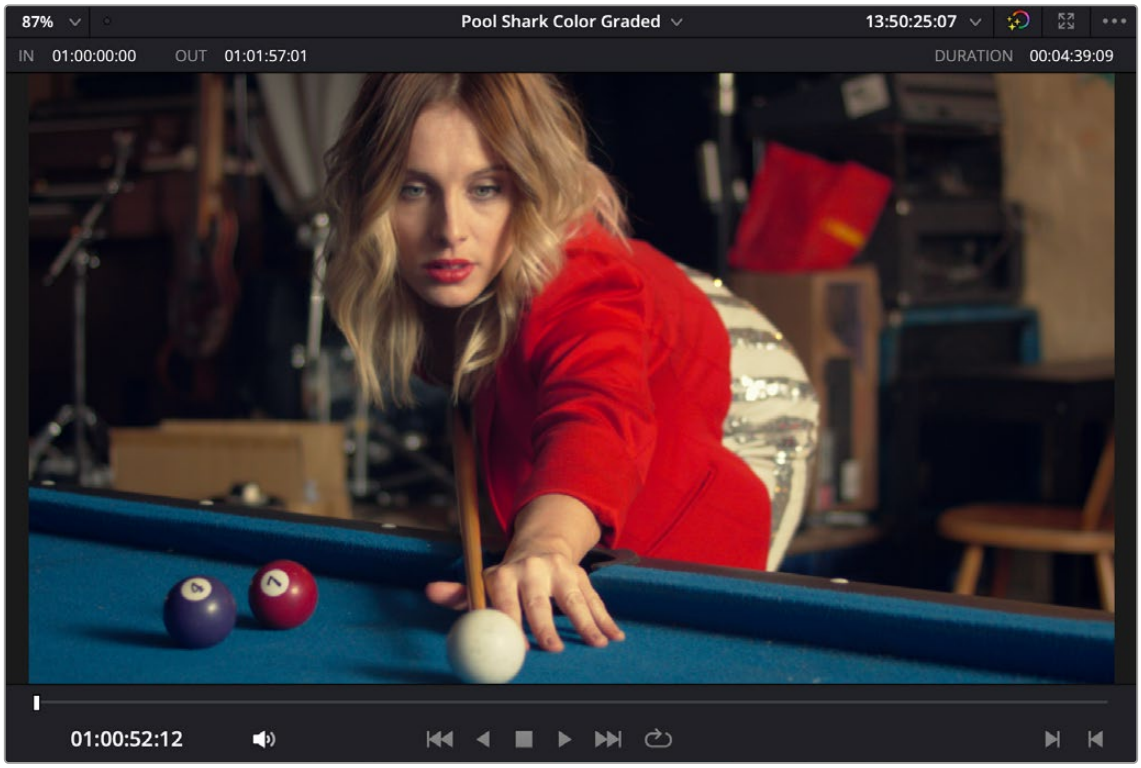
When you filter the Thumbnail timeline, you can only set up jobs to render in Individual Clips mode. You can tell if Thumbnail filtering is enabled by an orange underline under the Clips button in the UI toolbar.



An orange line under the Clips button shows that filtering is enabled

The Viewer

When rendering file-based media, the Viewer shows you exactly how the media being output will look using the current settings, and the transport controls move the playhead throughout the current Timeline. Audio playback can be turned on or off by clicking on the speaker icon, or adjust the level by right-clicking on the speaker icon and dragging the slider.



Deliver page Viewer

When outputting to tape, the Viewer shows you the tape output so you can set up insert or assembly edit points, and the transport controls move the tape in the deck if device control is enabled. You can also put the Viewer into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (P), so that it fills the entire screen. This command toggles Cinema Viewer mode on and off.

Disabling Viewer Updates While Rendering

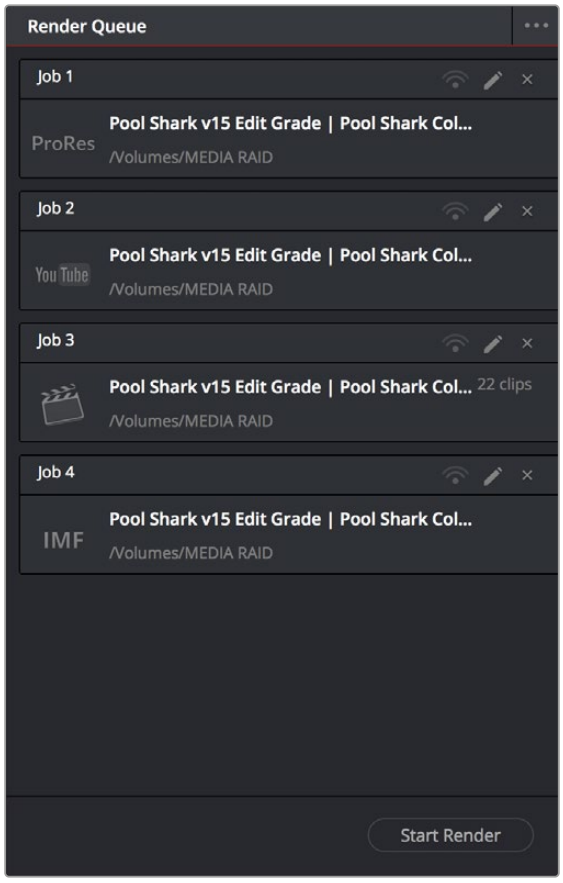
An Updates During Renders submenu in the Render page Viewer option menu lets you choose to disable, minimize, or enable Viewer updates while a program is being rendered. Disabled or minimized Viewer updates will speed rendering, especially on slower workstations.

The Render Queue

The Render Queue is a list of all the jobs you've queued up for delivery. Each job can have an individualized range of clips and render settings, which you can use to render multiple sections or clips of a timeline, the same timeline output to multiple formats, or multiple timelines.

The Render Queue also has the option to show either just the jobs within the current project, or jobs queued up and saved within all projects in the currently open SQL network project library (for the current user) or local project library (at the currently selected disk location). This can be exceptionally useful in situations where you've broken a program into multiple reels, with each reel being a different project. This can be turned on and off via the "Show All Projects" option of the Render Queue Option menu.

Jobs in the Render Queue can be edited (by clicking the pencil button), they can be assigned to remote rendering workstations, and they can be deleted. Jobs that have already been rendered can be kept in the Render Queue and re-rendered at a later time.

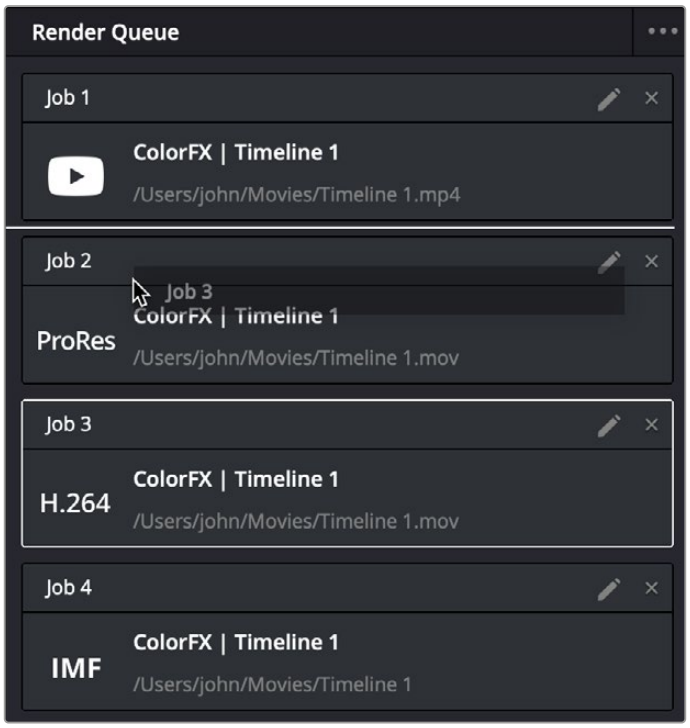


The Render Queue displays all jobs

TIP: There is an option to show the Render Settings of each item in the Render Queue, by selecting "Show Job Details" in the Render Queue Option menu. This provides specific details of each job's dimensions, frame rate, codec etc. This is a great help in managing a complex render queue at a glance.

Drag to Reorder Jobs in the Render Queue

You can manually reorder the Render Queue by dragging a job up and down in the stack. The job numbers will remain in numerical order, but the actual render settings assigned to them will be replaced.



Dragging Job 3 (H.264) in front of Job 2 (ProRes) in the Render Queue.

Chapter 184

Rendering Media

This section describes the options that are available for file-based delivery.

The workflow is simple; you define the format and other settings that dictate how the media is to be rendered, define a range of clips in the currently selected session, and then add a job containing these settings to the Render Queue.

You can queue up as many different render jobs as you like, each with different formats, output options, and ranges of clips, depending on what you're trying to accomplish. When you're ready to render, simply click the Start Render button.

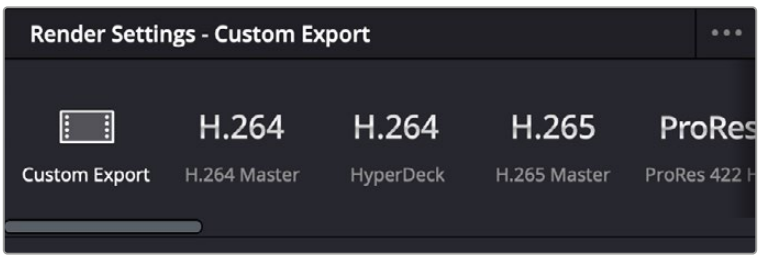
Using Presets for Fast Rendering

The very top of the Render Settings list has a set of presets for many of the most common rendering workflows you'll need to accomplish. If you want to create your very own settings, then choose custom. Each preset automatically sets up what you need and locks you out of settings that are not necessary for rendering that type of media.



Render presets selection

Custom

When custom is selected, nothing is automatically set, and all conventional media rendering options are available, except for those that are specifically associated with particular presets. You must manually choose the settings and options you need. All Render settings are saved on a per-project basis.

Social Media Presets

These presets let you render media specifically for video sharing services, with the option to upload the rendered files automatically.

YouTube 720p/1080p/1440p/2160p

A dropdown menu lets you choose four different resolutions to render to and selects the appropriate settings for exporting your program as a file suitable for uploading to YouTube and many other video file sharing services. The preset renders a single clip at the timeline's frame rate and sets the following parameters:

- **Format:** MP4
- **Video Codec:** H.264
- **Encoding Profile:** High
- **Audio:** Main 1
- **Audio Codec:** AAC
- **Data burn-in:** Same as Project
- **Normalize Audio:** Checking this box will normalize the clip's audio level to YouTube's standard.
- **Use Proxy Media:** Lets your final render use the proxy media instead of the original source camera files. Useful if speed is more important than quality.
- **Render without Timecode:** If you're using certain editing tools on mobile devices that have issues with timecode, checking this box lets you Render without Timecode,

- **Upload directly to YouTube:** When this box is checked, the resulting render will automatically upload to your YouTube account, and the following parameters will become available. If you have multiple YouTube Channels on your account, you can select which channel to upload to.

  Title: Enter the title of your video.

  Description: Enter a description of your video.

  Chapters from Markers: Checking this box embeds chapter points in the YouTube video corresponding to the the selected marker color and the marker's position on the Timeline.

  Upload Thumbnail: Checking this box will open a file browser, allowing you to select a still image that will become the thumbnail image for your video on YouTube.

  Visibility: You can change how your video will be accessible on YouTube.

  Category: You can select your video's YouTube category.

Vimeo 720p/1080p/2160p

A dropdown menu lets you choose three different resolutions to render to and selects the appropriate settings for exporting your program as a file suitable for uploading to Vimeo and many other video file sharing services. The preset renders a single clip at the timeline's frame rate and sets the following parameters:

- **Format:** MP4
- **Video Codec:** H.264
- **Encoding Profile:** Auto
- **Audio:** Bus 1
- **Audio Codec:** AAC
- **Data burn-in:** Same as Project
- **Use Proxy Media:** Lets your final render use the proxy media instead of the original source camera files. Useful if speed is more important than quality.
- **Upload directly to Vimeo:** When this box is checked, the resulting render will automatically upload to your Vimeo account, and the following parameters will become available.

  Title: Enter the title of your video.

  Description: Enter a description of your video.

  Visible To: You can change how your video will be accessible on Vimeo, including password protection.

TikTok Deliver Page Preset

A dropdown menu lets you choose two different resolutions to render to and selects the appropriate settings for exporting your program as a file suitable for uploading to TikTok and many other video file sharing services. The preset renders a single clip and sets the following parameters:

- **Resolution:** 1920x1080 HD
- **Use Vertical Resolution:** Unchecked. Check this box if you want to deliver your video in portrait mode for proper display on phones. This should be on for TikTok.
- **Frame rate:** The chosen frame rate of your timeline. You can also override this and set another frame rate manually.
- **Format:** MP4
- **Video Codec:** H.264
- **Encoding Profile:** Auto
- **Audio:** Bus 1

- **Audio Codec:** AAC
- **Data burn-in:** Same as Project
- **Use Proxy Media:** Lets your final render use the proxy media instead of the original source camera files. Useful if speed is more important than quality.
- **Upload directly to TikTok:** When this box is checked, the resulting render will automatically upload to your TikTok account, and the following parameters will become available.

  Title: Enter the title of your video.

  Visible To: Lets you choose who will be able to view this video. The options are Private, Public, and Friends.

  Allow comments: Checking this box allows commenting on your TikTok video. Un-checking this box forbids comments on your video.

  Allow Duet: Checking this box will allow your video to be used side-by-side with a video from another creator in TikTok using the Duet function.

  Allow Stitch: Checking this box will allow your video to be edited and combined with a video from another creator in TikTok using the Stitch function.

Presentations Preset

This setting lets you flag and format timelines to be used with Presentations in Blackmagic Cloud. Unlike other presets, there are no codec settings to choose from. This setting simply adds the metadata necessary for Presentations to share your timeline. You must have already created a Presentation in Blackmagic Cloud before you can use this setting.

- **File Name:** Choose the name of the timeline to be uploaded to Presentations.
- **Upload To:** Choose the name of the existing Blackmagic Cloud Presentation to upload to.
- **Use Proxy Media:** Use the Proxy Media as the source for the compression and upload to Blackmagic Cloud rather than the original media.

Dropbox or Dropbox Replay 720p/1080p/2160p

A dropdown menu lets you choose three different resolutions to render to and selects the appropriate settings for exporting your program as a file suitable for uploading to Dropbox and many other video file sharing services.

The preset renders a single clip at the timeline's frame rate and sets the following parameters:

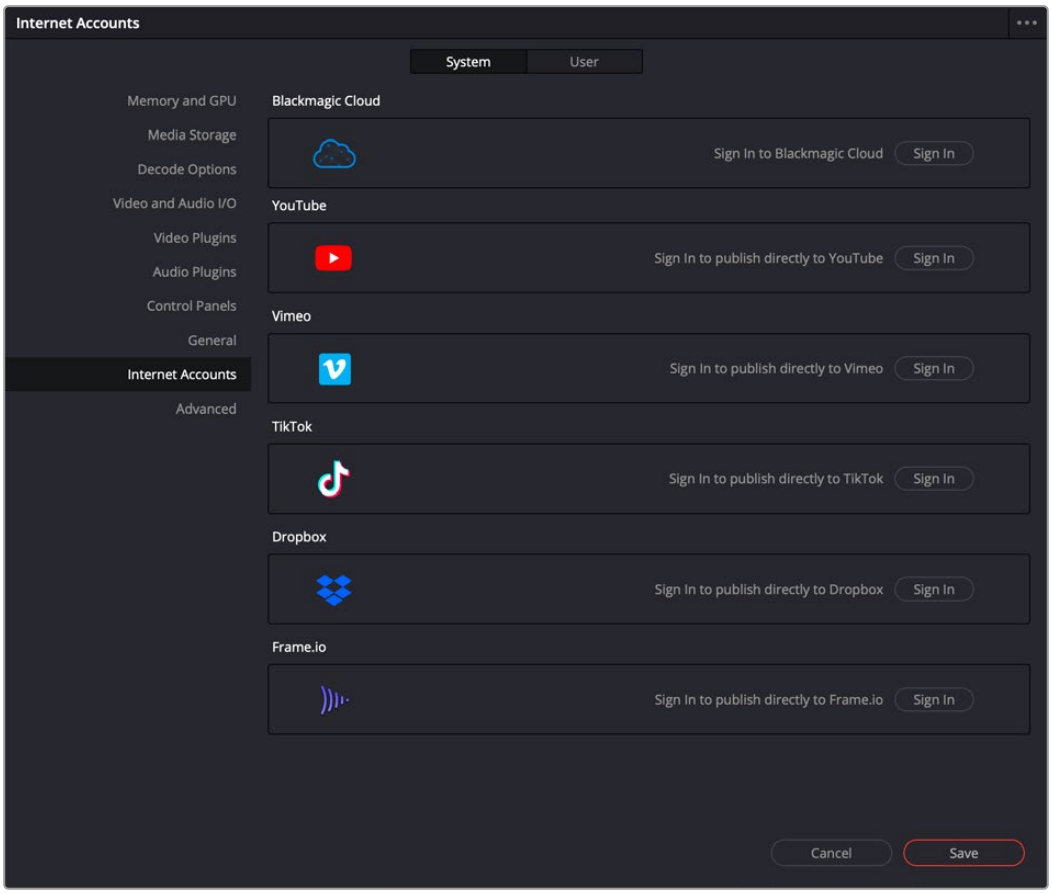
- **Format:** MP4
- **Video Codec:** H.264
- **Encoding Profile:** Auto
- **Audio:** Bus 1
- **Audio Codec:** AAC
- **Data burn-in:** Same as Project
- **Use Proxy Media:** Lets your final render use the proxy media instead of the original source camera files. Useful if speed is more important than quality.
- **Upload directly to Dropbox:** When this box is checked, the resulting render will automatically upload to your Dropbox account.

Setting Up Video Sharing Uploads

DaVinci Resolve has account integration with YouTube, Vimeo, TikTok, Dropbox, and Frame.io that allows you to render and upload directly to each service. An Internet Accounts panel in the System tab of the DaVinci Resolve Preferences lets you sign into your YouTube, Vimeo, Dropbox, and Frame.io accounts, as well as specify a local cache location for media being synced with Frame.io.

For each service you sign into, a floating window presents the interface in which you'll need to enter your login name and password to enable integration, followed by whatever two-factor identification and other required steps are necessary. Once entered, DaVinci Resolve will sign in to each of these services automatically when DaVinci Resolve opens.

For each service you sign into, the service's upload parameters will also be available in the Custom Export Video settings in the Deliver page. This allows you to create your own custom file settings that can supersede the normal formats allowed by the service presets, while allowing you the convenience of the all-in-one uploading and description entry of the preset.



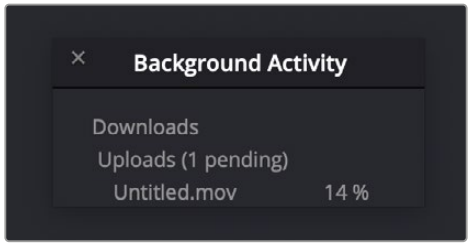
The Internet Accounts panel of the System tab of the DaVinci Resolve Preferences window

NOTE: For Frame.io, the local cache location is used to store clips you import into a DaVinci Resolve project from the Frame.io volume in the Media Storage panel of the Media page.

Deliver and Upload to Social Media

When you've configured YouTube, Vimeo, TikTok or Dropbox access in the Internet Accounts panel of the System Preferences, the YouTube, Vimeo, and Dropbox presets expose an "Upload directly to YouTube/Vimeo/TikTok/Dropbox" checkbox, which lets you choose whether or not to automatically upload the rendered result.

Choose the desired export options, then click the Add to Render Queue button to add this job to the Render Queue as you would with any other export. When that job is rendered, it automatically proceeds to upload to the selected video sharing service, and an upload percentage indicator appears in the job listing to show how far along this upload is. This upload is done in the background, so you can continue working on other things in DaVinci Resolve while the file uploads. If you want to see how long the upload will take on any other page, you can choose Workspace > Background Activity to see the Background Activity window.



Waiting for your movie to upload

Once the upload is finished, you can view the file directly on the social media site in a web browser by right-clicking on the job in the Render Queue and selecting Reveal in Browser.

Review Before Upload

For an extra level of quality control before you send your video out live on the internet, you can select Review Before Upload from the Render Queue option menu. This option will pause the automatic upload process after the file has been rendered with a message, "Waiting for Upload." You can then right-click on the job in the Render Queue, and select Reveal in Finder to open and review your video. Once you've made your decision, from that same menu, you can select either Upload to (service name) to let your video go, or Cancel Upload if you've had second thoughts.

ProRes Master

For quickly outputting ProRes Master files of a whole program. When selected, defaults to rendering in single clip mode, with the Format set to QuickTime, the Codec set to Apple ProRes, and the Type set to Apple ProRes 422 HQ. Audio defaults to the Codec being Linear PCM and the Bit Depth being 16.

H.264 Master

For outputting H.264 files of a whole program. When selected, defaults to rendering in single clip mode, with the Format set to QuickTime, and the Codec set to H.264. Quality, Encoding Profile, and Entropy Mode are set to Auto, Passes defaults to Single, and Key Frames default to Automatic with Frame Reordering turned on. Audio defaults to the Codec being AAC with the Data Rate set to 320 Kb/s and the Bit Depth set to 16.

H.265 Master

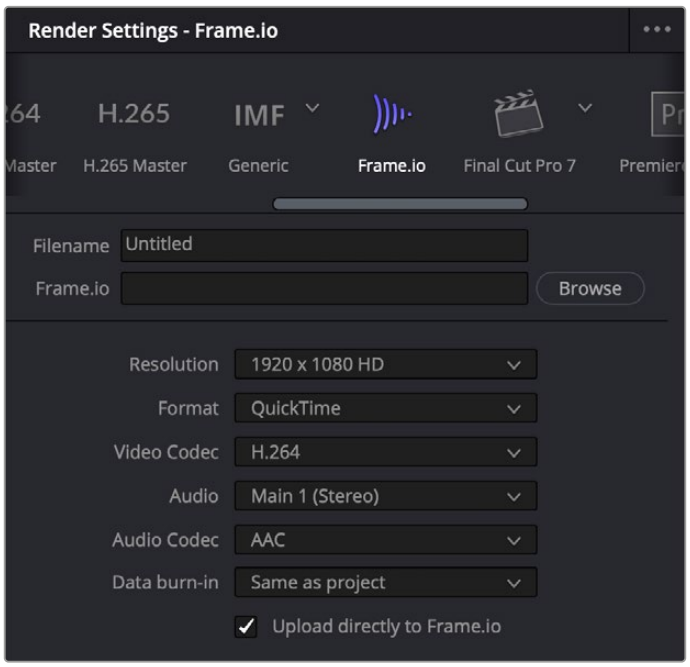
For outputting H.265 files of a whole program. When selected, defaults to rendering in single clip mode, with the Format set to QuickTime, and the Codec set to H.265. Quality is set to Automatic, Encoding Profile is set to Main, Passes defaults to Single, and Key Frames default to Automatic with Frame Reordering turned on. Audio defaults to the Codec being AAC with the Data Rate set to 320 Kb/s and the Bit Depth set to 16.

IMF (Studio Version Only)

A dropdown menu to the right of this preset provides options for Generic, 20th Century Fox, and Netflix-qualified presets. This preset is for facilities that deliver IMF files as digital-only deliverables. A Preset Type dropdown lets you choose the appropriate settings to populate the various locked IMF-specific parameters that appear.

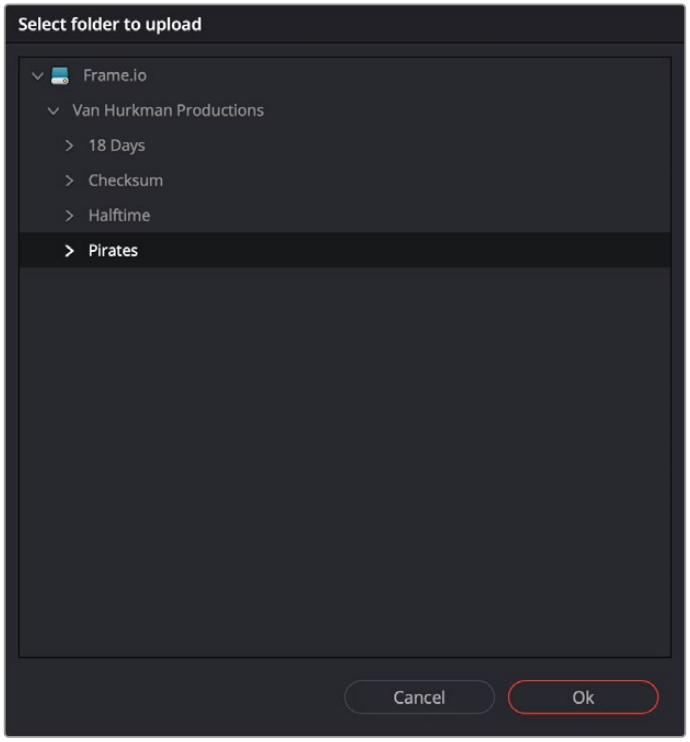
Frame.io

A Frame.io preset at the top of the Deliver page's Render Settings panel lets you render and upload a program for review. All options in the Render Settings panel update to present suitable controls for this process. At the bottom of the Render Settings list, an "Upload directly to Frame.io" checkbox lets you choose whether or not to upload the rendered result. A Description field lets you add a description to be uploaded along with the rendered media.



Choosing the Frame.io preset

When you choose the Frame.io preset, the Location field turns into a Frame.io field, and the Browse button lets you choose a project and folder path to which to upload the exported result.



Choosing a Frame.io account to deliver a program to

When you export to Frame.io, the available choices in the Resolution, Format, Video Codec, and Type dropdown menus are limited to those that are most suitable for Frame.io file sharing. Choose the desired export options, then click the Add to Render Queue button to add this job to the Render Queue as you would with any other export. When that job is rendered, it automatically proceeds to upload to Frame.io, and an upload percentage indicator appears in the job listing to show how far along this upload is. This upload is done in the background, so you can continue working on other things in DaVinci Resolve while the file uploads. If you want to see how long the upload will take on any other page, you can choose Workspace > Background Activity to see the Background Activity window.

For more information about Frame.io integration, *see Chapter 13, "Frame.io and Dropbox Replay Integration."*

Final Cut Pro 7 or X XML

A dropdown menu attached to this preset lets you choose from two different XML formats to be exported along with the media you're rendering:

- Selects the appropriate settings for projects that were sent from Final Cut Pro 7 to DaVinci Resolve using XML. This is meant for situations when you're rendering media intended for a return trip to Final Cut Pro (by exporting an XML file from the Edit page). Renders Individual Clips, the "Codec" setting on macOS, defaults to Apple ProRes 422 (HQ), Output Size defaults to the current Timeline Resolution (as set in the Master Settings panel of the Project Settings), and Use Unique Filenames is turned on.

  When you choose this preset, an XML of the timeline is automatically exported along with the media, with path names that reflect the rendered clips.

- Selects the appropriate settings for projects that were sent from Final Cut Pro X to DaVinci Resolve using XML. This is meant for situations when you're rendering media intended for a return trip to Final Cut Pro X (by exporting an FCPXML file from the Edit page). Renders Individual Clips, the "Codec" setting on macOS, defaults to Apple ProRes 422 (HQ), Output Size defaults to the current Timeline Resolution (as set in the Master Settings panel of the Project Settings), and Use Unique Filenames is turned on.

  When you choose this preset, an XML of the timeline is automatically exported along with the media, with path names that reflect the rendered clips.

Premiere XML

Selects the appropriate settings for projects that were sent from Premiere Pro to DaVinci Resolve using XML. This is meant for situations when you're rendering media intended for a return trip to Premiere Pro. Renders Individual Clips, the "Codec" setting on macOS defaults to Apple ProRes 422 (HQ), Output Size defaults to the current Timeline Resolution (as set in the Master Settings panel of the Project Settings), and Use Unique Filenames is turned on.

When you choose this preset, an XML of the rendered timeline is automatically exported along with the media, with path names that reflect the rendered clips.

Avid AAF

Selects the appropriate settings for projects that were sent from Avid Media Composer or Symphony to DaVinci Resolve using AAF. This setting is NOT for exporting to Pro Tools. This is meant for situations when you're rendering media intended for a return trip to Media Composer (by exporting an AAF file from the Edit page). The "Codec" setting defaults to DNxHR 444 12 bit, Output Size defaults to the current Timeline Resolution (as set in the Master Settings panel of the Project Settings), and Render Clip with Unique Filename is turned on.

When you choose this preset, an AAF of the timeline is automatically exported along with the media, with path names that reflect the rendered clips.

Pro Tools

As of DaVinci Resolve version 16, Pro Tools export has been dramatically improved. This preset presents the appropriate options for exporting a specifically formatted AAF project file, linked audio files, and a linked reference video file to Pro Tools, or any application capable of importing a Pro Tools formatted AAF file.

When exporting using the Pro Tools preset, you must use the AAF file that's automatically created and written to the target location, because it's formatted specially for Pro Tools and it contains path names reflecting the rendered clips. Do not export an AAF using the File > Export AAF/XML command, as this will not provide the correct exchange file for Pro Tools, and it won't work correctly.

When you use the Pro Tools preset, DaVinci Resolve outputs the following:

1. What you choose in the Codec dropdown menu of the Audio panel dictates whether you export the audio from the Timeline as a collection of files that link to a separate AAF, or an AAF with audio file embedded within as a single deliverable.
   - Choose Linear PCM to export individual files linked to a separate AAF interchange file
   - Choose Embedded in AAF to export an AAF with embedded Broadcast WAV audio files within it as a single deliverable

   Whether you export separate files or a single embedded AAF deliverable, each of the audio clips in the current Timeline can be exported as individual mono or multichannel audio files. The standard mono round trip export from DaVinci Resolve to Pro Tools is the default setting, with

the “Render one track per channel” box checked in the Audio tab of the Pro Tools Render Setting. With this option, a 5.1 polyphonic .wav file would be exported as six individual mono .wav files.

If the “Render one track per channel” box is unchecked, DaVinci Resolve will output multichannel polyphonic .wav files instead. If you do this, it’s important to check in advance that Pro Tools supports the particular multi-channel formats you want to export before committing to this workflow.

Each exported file contains every audio channel from the source media, regardless of channels that have been been muted in the audio panel of Clip Attributes. This means no matter how the video editor organized the channels of audio in the Timeline, you’ll always deliver every channel of each audio clip to whomever is doing your audio postproduction.

2 You can also choose to include handles using the “Add X frame handles” option in the Advanced Settings of the Video panel to add extra frames to the beginning and end of each exported audio clip. This will provide needed editing flexibility to whomever is refining your audio.

3 The type of audio file that’s exported is determined by your choice of video format in the Video panel:

- If you choose the MXF OP-Atom video format, then MXF audio files will be exported.
- If you choose the QuickTime format, then Broadcast Wave files will be exported.

4 All video in your timeline will be rendered and output as a single reference movie, in the format that’s selected in the Video panel, with all effects and titles baked in. Subtitles can also be burned into the reference movie or exported as a file. If you want to provide a window burn, you can enable visible metadata using the Workspace > Data Burn-In window. If you do not wish to export a reference movie, you can uncheck the Export Video box in the Video panel.

When you output using the Pro Tools preset, an AAF of the audio tracks of the current Timeline is exported that’s formatted for import into Pro Tools, or any other digital audio workstation (DAW) software that’s compatible with the Pro Tools style of AAF import.

- Exported audio files have the file name and timecode of the source media they were extracted from, to enable relinking to the source media in Pro Tools, if necessary. In the case of Video+Audio files that have been synced in DaVinci Resolve, exported audio files are given the timecode and name of the synced audio source file, not that of the video clip.
- Each audio track exports whatever custom name you may have given it, for use by Pro Tools.
- All track and clip volume automation is exported, with all keyframes.
- iXML metadata is also exported, including channel names when available.

IMPORTANT: When you export to Pro Tools in the Deliver page, audio effects are neither exported nor baked in, which means that FairlightFX, EQ, Compression, Pitch, and Elastic Wave effects will be ignored. If you are experiencing problems with imported AAF files, check to see if there are audio effects or audio compound clips in the Timeline, and replace any you find with duplicates of the same audio clips that have no effects.

Audio Only

This preset is specifically for rendering an audio-only media file from the Timeline. Video rendering is disabled, and this preset defaults to rendering the Main 1 bus as a single clip, rendering one track per channel using the MXF OP-Atom format set to the Linear PCM codec, at 16-bits. However, the QuickTime, MP4, and WAV formats are also available, and you can also render 24- or 32-bit output. Additionally, you have the option to render other Mains or Submixes, or to choose a specific Timeline Track to render. Finally, you can choose to render the current program as Individual Clips.

Creating and Using Your Own Presets

If there is a particular group of settings that you find yourself using repeatedly, you can turn it into a custom Easy Setup, for easy recall.

To create a new Easy Setup:

1. If you want to start from scratch, make sure to choose Custom from the preset panel to unlock every setting in the Render Settings pane.
2. Choose the particular settings you require in the Video, Audio, and File panels for your new preset.
3. Open the Render Settings Options menu, and choose Save as New Preset.
4. Type a name into the “Render Preset” dialog, and click Save. The new preset now appears in the Preset panel.

To load a preset:

- Click any preset. Every setting in the Render Settings pane updates to reflect the preset you selected.

To change a custom preset that you’ve created

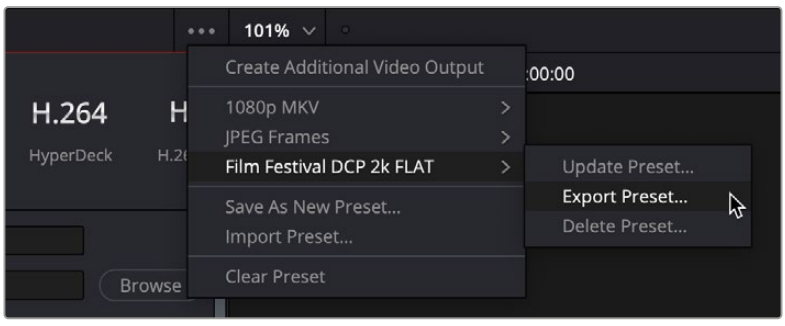
- Click a preset you want to change, make whatever changes you need to in the Video, Audio, and File panels, then click the Render Settings Option menu, and choose Update Current Preset.

To delete a custom preset that you’ve created:

- Click a preset you want to delete, then click the Render Settings Option menu, and choose Delete Current Preset.

Import and Export Custom Presets

Custom render presets that you create can be imported and exported from the Deliver page. Presets are saved in .xml files that can be easily sent to other users or workstations to ensure the exact same delivery methods are used between machines. In addition, any newly created export presets are available in the “Add to Render Queue Using” menu when you right-click a timeline.



Render presets can now be imported and exported from the Deliver page.

To save a custom render preset:

1. In the Deliver page, adjust the Video, Audio, and File options in the Render Settings to your needs.
2. In the Render Settings Option (3-dot) menu, select Save as New Preset.
3. Enter a name for the new preset, and press OK.

   The new preset will be available in the Render Settings Option menu, as well as an option in the Custom Preset Settings icon in the Render Presets row at the top of the Render Settings.

To export a custom render preset:

1. In the Deliver page, click on the Render Settings Option (3-dot) menu.
2. Select the name of the saved preset you wish to export.
3. Select Export Preset from the dropdown menu.
4. Use the file browser to name and set the save location of the preset.

   The new preset will be available as an .xml file.

To import a custom render preset:

1. In the Deliver page, click on the Render Settings Option (3-dot) menu.
2. Select Import Preset from the dropdown menu.
3. Select the Render Setting .xml file in your file browser.
4. Press Open.

   The imported preset will be available in the Render Settings Option menu, as well as an option in the Custom Preset Settings icon in the Render Presets row at the top of the Render Settings.

To update a custom render preset with new settings:

1. Make any changes you wish to the Video, Audio or File Render Settings.
2. In the Deliver page, click on the Render Settings Option (3-dot) menu.
3. Select the name of the saved preset you wish to update.
4. Select Update Preset from the dropdown menu.
5. Press the Update Button from the warning dialog. This action can not be undone.

   The selected preset will be updated with the new settings you selected.

To delete a custom render preset:

1. In the Deliver page, click on the Render Settings Option (3-dot) menu.
2. Select the name of the saved preset you wish to delete.
3. Select Delete Preset from the dropdown menu.
4. Press the Delete Button from the warning dialog. This action can not be undone.

   The selected preset will be permanently deleted from the Render Presets list.

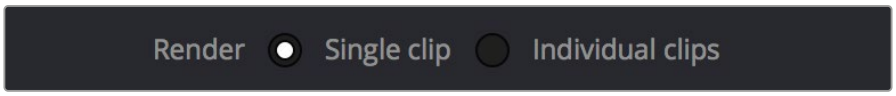
Choosing a Location to Render

The first decision you have to make when rendering your output is where it's going to be rendered. Accordingly, this is the first set of controls appearing at the top of the Render Settings parameters.

- **Filename:** A preview of what the file name will be based on the settings found in the File panel described later. The Custom/Timeline name and File suffix fields, as well as the "Use x digits in the filename" settings all determine what name appears here. The editable portions of this filename preview can also be edited here.
- **Location:** Click the Browse button to choose a directory in which to write the media being output by DaVinci Resolve. After you've selected a directory, the path name appears in the "Render job to" field.

Single Clip vs. Individual Clips

While there are numerous options available in the Render Settings of the Deliver page, there are basically two overarching ways you can render your project, depending on which of the "Render" radio buttons you click in the Output group.



Render a single clip or individual clips

Single Clip

When you select the Single clip option, you're setting up a render wherein all clips in the session are output together, as a single media file in whatever format you choose. This means you'll be rendering the selected range of the session to a single MXF or QuickTime file, or as a single collection of image sequences.

- **Timecode:** The timecode that's written out is dictated by the "Start timeline timecode at" setting of the timeline being rendered. Media files contain a continuous timecode track, while image sequences have timecode written into each frame's data header, and integrated into the file name (as a frame count).
- **Frame Rate:** If you're rendering a project that uses mixed frame rates, rendering to a single clip converts every clip in the entire session to the project frame rate, using either the project-wide or clip specific "Retime process" setting.
- **Effects:** Most effects are "baked into" the rendered output when you render a single clip.

IMPORTANT: Whenever clip filtering is enabled (via the dropdown menu to the right of the Clips button), Single Clip rendering cannot be selected. You can see if clip filtering is enabled by an orange line underneath the Clips button in the UI toolbar.

Individual Clips

Selecting the Individual clips option sets up a render where each clip is rendered as an individual media file in whichever format you choose. The result will be a collection of as many media files as there are clips in the range you've selected to render.

- **Timecode:** The timecode written to each clip is cloned from the original source media, making it easy to reconform media for projects being passed between DaVinci Resolve and NLEs.
- **Frame Rate:** If you're rendering a project that uses mixed frame rates, rendering to source renders each clip at its own individual frame rate, to accommodate round-trip workflows.
- **Effects:** You can choose whether any timeline-based effects are either ignored or "baked into" the individual clips by checking/unchecking the Render Timeline Effects box.
- **Resolution:** You can choose whether the individual clips are rendered at the timeline size or their original source resolution by checking/unchecking the Render at Source Resolution box.

All Other Render Settings for Output

This section covers the different render settings that are available for customizing your output. Depending on which Render Setting mode you chose, some of these may be hidden, but this section covers the full list found in the Advanced panel of controls.

If you choose one of the Easy Setups, then some of these settings will be locked, and others will be editable, depending on the requirements of that setup. If none of the Easy Setups is suitable for the task at hand, you can leave the Easy Setup dropdown menu set to none, and manually choose the necessary settings for the task at hand.

Video Panel

This panel contains all video-oriented parameters.

Format and Codec Controls

These top-level parameters let you choose whether or not to render video, and which format to render it to. Depending on which Format, Codec, and Type you choose, other options may or may not appear.

- **Export Video:** Turn this checkbox on to render the source video. Turn this checkbox off if you want to render the source audio all by itself; this disables all video controls, and shows an Audio Format dropdown menu in the audio section of settings.
- **Format:** A dropdown menu that gives access to the container formats that are currently available on your system. The available options depend on whether you have Final Cut Pro and QuickTime installed, and on the operating system you're using. This list is constantly growing, as new file formats are added over time, so be sure to check each new version for the latest supported formats.

  AVI: A now-deprecated file-based media format that, despite its age, remains popular with Windows applications. Supports delivery using the Cineform, Grass Valley HQ and HQX, and Uncompressed RGB and YUV codecs.

  Cineon: An older uncompressed image sequence format developed by Kodak, designed for film scanning and digital mastering, which delivers RGB 10-bit.

  DCP: Native DCP encoding and decoding for creating unencoded DCP files only. If you have a license for Frauenhofer's EasyDCP, a setting in the Configuration panel of the System Preferences enables you to choose whether to use EasyDCP (for creating encrypted DCP output), or the native DaVinci Resolve encoding.

DPX: An uncompressed image sequence format favored by the film industry for mastering and delivery for DCDM mastering, which can be delivered as RGB 10-, 12-, 16-bit integer and half float, or RGBA 8-bit.

easyDCP: (when installed) An option that allows you to master a DCP or IMF directly from DaVinci Resolve in conjunction when you have an installed license of Fraunhofer's EasyDCP software.

EXR: The OpenEXR format is a high-dynamic-range image sequence format developed by ILM for applications requiring high quality and multiple channels. Used for outputting ACES and HDR deliverables. You can deliver to a variety of RGB Half and RGB Float settings. When choosing the RGB half (DWAA) or (DWAB) compression codecs, an additional "Compression level" setting appears that lets you choose how much compression to apply.

IMF: A native IMF encoding option that lets you export to the SMPTE ST.2067 Interoperable Master Format (IMF) for tapeless deliverables to networks and distributors, with support for encoding of JPEG2000 using a library licensed from Kakadu software. No additional licenses or plugins are required to output to IMF. The IMF format supports multiple tracks of video, multiple tracks of audio, and multiple subtitle and closed caption tracks, all of which are meant to accommodate multiple output formats and languages from a single deliverable. This is done by wrapping a timeline's different video and audio tracks (media essences) and subtitle tracks (data essences) into a "composition" within the Material eXchange Format (MXF).

JPEG 2000: DaVinci Resolve 15 introduced support for the encoding and decoding of JPEG2000 using a library licensed from Kakadu software. This includes a complete implementation of the JPEG2000 Part 1 standard, as well as much of Parts 2 and 3. JPEG2000 is commonly used for IMF and DCP workflows.

MJ2: The Motion JPEG 2000 format. DaVinci Resolve 15 introduced support for the encoding and decoding of JPEG2000 using a library licensed from Kakadu software. This includes a complete implementation of the JPEG2000 Part 1 standard, as well as much of Parts 2 and 3. JPEG2000 is commonly used for IMF and DCP workflows.

MP4: Dedicated MP4 encoding lets you export H.264-encoded movies.

MXF OP–Atom: A simple standard for the Material eXchange Format, a file-based media format, that's often used when delivering DNxHD. This version conforms to the SMPTE 390M standard, and can deliver using the DNxHD, DNxHR, Kakadu JPEG 2000, NTSC and PAL Avid, RGB Avid 10-bit, and XDCAM MPEG2 codec options.

MXF OP1A: A version of the Material eXchange Format that conforms to the SMPTE 378M standard, and can deliver using the 1080i Avid 8-bit, DNxHD, DNxHR, Kakadu JPEG 2000, NTSC and PAL Avid, RGB Avid 10-bit, Sony MPEG4 422 and 444, and Sony XAVC Intra CBG and VBR, and XDCAM MPEG2 codec options.

QuickTime: Apple's file-based media format, used when delivering Apple ProRes, DNxHD or DNxHR wrapped in QuickTime, GoPro Cineform RGB 16-bit and YUV 10-bit, Grass Valley HQ and HQX, Kakadu JPEG 2000, H.264, HEVC, H.265 (single or multi-pass), Photo JPEG, Kakadu JPEG 2000, Uncompressed 8- and 10-bit formats with ARGB/BGRA/RGB/YUV channel orders, and VP9 at 8-, 10-, and 12-bits.

TIFF: "Tagged Image File Format," an image sequence format compatible with many desktop video applications on many platforms and is also used when delivering for DCDM mastering.

- **Codec:** A dropdown menu that lets you choose from a selection of codecs that are available to the format you've selected above.
- **Type:** Different codec options may also present different bit depth and color space combinations, as well, which are available from this menu.
- **Maximum Bit Rate:** (Does not appear for all codecs) Codecs such as Kakadu JPEG 2000 let you specify a maximum bit rate, in Mbits per second, with which to encode the delivered video.

- **Field rendering:** If you're processing interlaced source material, this checkbox sets DaVinci Resolve to render each field individually before reintegrating them back into a single frame, in order to process clips most accurately with filtering operations that would otherwise violate field boundaries and cause problems. If you're not rendering interlaced media, you should leave this checkbox turned off, as it is more processing intensive.
- **Export HDR10 Metadata:** (Available in Single clip mode if HDR10+ is enabled in Project Settings) Exports HDR10 metadata to the rendered file when you're doing an HDR workflow.
- **Embed HDR10 Metadata:** (Available in Single clip mode if HDR10+ is enabled in Project Settings) Exports HDR10 metadata to the rendered file when you're doing an HDR workflow. Embeds HDR10 metadata within the exported media of selected formats.
- **Embed HDR Vivid Metadata:** Exports HDR Vivid metadata to the rendered file when you're doing an HDR workflow. Embeds HDR Vivid metadata within the exported media of selected formats.
- **Render at Source Resolution:** (When rendering Individual Clips) This checkbox lets you render each clip at the same resolution as its source media file, letting you preserve mixed frame sizes for final delivery.
- **Resolution:** The output resolution for rendering. This setting defaults to Timeline Resolution; this lets you create a preset that automatically updates its resolution settings dynamically and automatically changed to the currently loaded timeline/project. However, you can change the resolution here if you want to set a specific resolution for the preset. Using this setting, you can queue up different render jobs at different resolutions, in order to output both HD and SD resolution media in the same render session, for example. Some file formats require specific resolutions, in which case the Output Size settings will be automatically set to the necessary resolution.
- **Frame rate:** (When rendering Single Clip) This setting defaults to the Timeline Frame Rate; this lets you create a preset that automatically updates its frame rate settings dynamically and automatically changed to the currently loaded timeline/project. However, you may wish to set this to a variation of the current conformed rate, for example choosing from between 23.98 or 24 fps. Doing so will adjust the metadata written within the file, which is used to aid playback for the range of systems available worldwide.

  3:2 Pulldown Insertion Options: Starting with DaVinci Resolve Studio 12.5, you have the option of outputting either 29.97 or 30 fps media with 3:2 pulldown insertion if your project's playback frame rate is either 23.98 or 24 fps. To output 29.97 media, the project must be 23.98 fps; simply choose (23.976 3:2) from the Frame rate dropdown. Projects with 24 fps frame rates can only be output at 30 fps.

- **Chapters from Markers:** (QuickTime or MP4 only) Embeds chapter points in the rendered file corresponding to the marker's position on the Timeline of the selected marker color.
- **Export Alpha:** (When rendering Individual Clips) Turning this checkbox on results in alpha channels found in each clip's source media file being output to each delivered clip, as well as alpha information that you're creating in DaVinci Resolve and inserting into that clip via the Alpha output of the Color page Node Editor being output to each delivered clip.
- **Alpha Mode:** (When rendering Individual Clips) Lets you choose how to export alpha channels when Export Alpha is enabled. You can choose Straight or Premultiplied.
- **Render Stereoscopic 3D:** (Only appears if there are stereo clips in a timeline) Three options let you choose how to render stereoscopic timelines, rendering just one eye's worth of media at a time, or rendering a single set of stereo media in one of four ways, depending on the option you choose from the "Both eyes as" dropdown menu.

  Left eye: Lets you render only the left-eye media from a stereo timeline.

  Right eye: Lets you render only the right-eye media from a stereo timeline.

  Both eyes as: Lets you select from four ways of rendering the left and right eyes of stereo media as a single set of media files. "Separate files" lets you output both the left-eye and right-eye media

as individual media files, all at once. Side-by-side, Line-by-Line, and Top-Bottom let you output frame-compatible media that can be output to stereo-capable displays. Anaglyph lets you output a traditional anaglyph red/cyan stereo image for viewing on any display using red/cyan glasses. MV-HEVC lets you output spatial video clips compatible with most VR headsets.

- **Use Constant Bit Rate:** If the Format and Codec you've specified allows you to switch between variable and constant bit rate output, this checkbox lets you force video to render at a constant bit rate.

Optional MP4, H.264, H.265, VP9, or HEVC Controls

If you choose MP4 as the format, or QuickTime with H.264, H.265, or VP9 as the codec, additional options appear, described below. Workstations using NVIDIA GPUs that offer NVENC will present alternative accelerated options, while other workstations offering QuickSync hardware encoding instead will be able to use that option.

- **Use hardware acceleration if available:** DaVinci Resolve supports QuickSync hardware encoding of H.264 and HEVC, if available on your workstation.
- **Quality:** If the currently selected option in the Render to dropdown menu has options for changing the compression quality, this dropdown menu lets you choose the quality you want to use. Otherwise, it's disabled.
- **Restrict to X Kb/s:** You can choose Automatic, or select a maximum data rate with which to export.
- **Encoding Profile:** A dropdown that lets you choose among different encoding profiles, each of which has been optimized for different purposes. The tradeoff is between quality and computational intensity for encoding and playback. The available options are:

  Auto: Automatically selects an encoding profile.

  Base: For H.264, intended for video conferencing and mobile phone use; highly compressed.

  Main: For H.264, intended for SD analog transmission. For H.265, intended for the compression of 4:2:0 video at up to 4K 60fps with a bit depth of 8-bits per channel.

  Main10: (H.265 only) Intended for the compression of 4:2:0 video at up to 4K 60fps with a bit depth of 10-bits per channel.

  Main 4:2:2 10: (H.265 only) Intended for the compression of 4:2:2 video at up to 4K 60fps with a bit depth of 10-bits per channel.

  High: For H.264, intended for Blu-Ray and HD transmission.

- **Entropy Mode:** (called Entropy Coding Mode for compatible Nvidia GPUs) A dropdown that lets you choose which algorithm the encoder should use for compression. The choices are:

  CALVC (context-adaptive variable-length encoding): A lower-quality algorithm that's less computationally intensive to process and play.

  CABAC (context-based adaptive binary arithmetic coding): A higher-quality algorithm that yields better visual quality at lower bandwidth, at the cost of being more computationally expensive to process and play.

- **Multi-pass encode:** (Available for QuickTime H.264 and H.265) You can choose between Single and Multi-pass encoding. Single pass is faster, but multi-pass yields superior results when quality is important. When you enable Multi-pass, the number of passes performed is automatic.
- **Key Frames:** (Available for QuickTime H.264 and H.265) You can choose Automatic, or select a duration for manual keyframe insertion.
- **Frame Reordering:** (Available for QuickTime H.264 and H.265) On by default, Frame Reordering enables the encoding of B frames to improve the quality of the resulting compressed movie file. Turning off Frame Reordering will speed encoding performance at the expense of visual quality.

- **Rate Control:** (Available for compatible NVIDIA GPUs) Provides six options for controlling Encoding Profile and Entropy Mode.
- **Lookahead:** (Available for compatible NVIDIA GPUs) Lets you specify how many frames for the encoder to examine in advance of compression.

Optional DCP and IMF Controls

If you choose DCP or IMF as the Format, additional options appear, described below.

- **Use interop packaging:** (DCP only, located under Type parameter) Lets you create an Interop DCP package, based on an earlier standard of DCP delivery that is not forward compatible with SMPTE DCP packages.
- **Package Type:** (IMF) Defaults to App2 Extended (App2e), for encoding JPEG 2000 up to 4K.
- **Bit Depth:** (IMF) The bit depth of the encoded IMF video.
- **Encoding Profile:** (IMF) A dropdown that lets you choose among Auto, IMF, and Broadcast.
- **Encoding Level:** (IMF) Provides different choices based on what is selected in Encoding Profile.
- **Maximum bit rate:** (DCP, IMF) Lets you choose how much to compress the result.
- **Lossless Compression:** (IMF) Lets you choose to encode using lossless compression.
- **Slope-Rate Control:** (DCP, IMF) A checkbox lets you specify lossless compression.
- **QStep:** (DCP, IMF) Lets you choose either automatic or manually specified DCP quantization levels at which to compress the video signal when using the Kakadu JPEG 2000 encoder.

Advanced Controls

An advanced settings disclosure button hides the following additional controls, by default.

- **Pixel aspect ratio:** Lets you override the Project Settings and change the PAR of the rendered output to either Square or Cinemascope.
- **Data levels:** Defaults to “Auto,” which simply renders all clips with the data level appropriate to the currently selected codec in the “Render to” dropdown menu, which is usually the preferred behavior. Choosing one of the other options (“Video” or “Full”) outputs all clips using the selected data range. For more information, *see Chapter 9, “Data Levels, Color Management, and ACES.”*

  Retain sub-black and super-white data: Turning this checkbox on lets you choose to output media files that preserve overshoots and undershoots, data that’s above the maximum and minimum data levels of the data level you’ve selected, assuming this is supported by the video format and codec you’re exporting to. Otherwise, DaVinci Resolve clips these “out-of-bounds” parts of the signal in an effort to keep your deliverables from violating whatever QC standards you’re adhering to in your grade.
- **Color Space Tag:** A dropdown menu that lets you choose a color space to embed as metadata in the rendered file. This setting defaults to Same as Project if your project’s color science is set to DaVinci YRGB Color Managed, or the ACES Output Device Transform if your color science is set to ACEScc or ACEScct. You can override this option manually from the choices on the dropdown menu.
- **Gamma Tag:** A dropdown menu that lets you choose the gamma to embed as metadata in the rendered file. This setting defaults to Same as Project if your project’s color science is set to DaVinci YRGB Color Managed, or you can override this option manually from the choices on the dropdown menu.
- **Data burn-in:** A dropdown menu that defaults to “Same as Project,” which leaves the current Data Burn In palette settings enabled while rendering, inserting a window burn into the media being output. Choosing “None” disables window burns while rendering. Note that when rendering as Individual Source Clips, individual clip burn in presets can be assigned if they’ve been created in the Data Burn In palette.

- **Bypass re-encode when possible:** Turning this checkbox on makes it possible to do a direct copy of the video essence of video items in the Timeline, directly from the source media to the file being output, when the selected Format, Codec, and Type matches the source. This also preserves Alpha channel data for compatible formats.

  Bypass re-encode eliminates the need to re-encode video media, preserves quality, and speeds up the output process dramatically, but it only works for clips in the Timeline to which no additional effects have been added. Doing any grading, adding a Resolve FX plugin, adding any overlapping effects or compositing to clips in the Timeline, resizing or stabilizing clips or altering the output sizing of the Timeline, and adding Fusion effects will all necessitate re-encoding the entire clip in order to process these effects. Transitions will require processing but only for the duration of each transition.

  There are many situations where this is valuable:

  Fast output of simple edits: You've edited a simple cuts-only promo using footage cut from a previously rendered program using QuickTime ProResHQ 422 media, and you're exporting to the exact same format. You can output all of the media very quickly using Bypass re-encode when possible.

  Fast output of previously output timelines with small changes: You need to replace a few shots in an effects-intensive program that's already been output. You can import the media file that was output into a new timeline, replace only the required shots with new media. DaVinci Resolve will do a direct copy of all previously rendered media, while re-encoding only the new clips with whatever effects and grading they contain. This lets you quickly re-output a high-quality master file, while preventing you from needing to re-render the entire program.

  Fast output of previously output timelines with new audio mixes: You've placed a previously rendered Video+Audio clip onto a timeline and edited a new audio mix clip to replace the old audio mix. In this situation, a new Video+Audio file will be quickly written with the new audio, but the video component of that file won't be re-encoded, again resulting in a fast export at the highest quality.

  TIP: For a list of which video formats are compatible with Bypass Re-encode on macOS, Windows, and Linux, as well as which formats are compatible with Alpha channels, see the "Supported Codec List" at the DaVinci Resolve Support page located at: https://www.blackmagicdesign.com/support/family/davinci-resolve-and-fusion.

- **Use optimized media:** When this checkbox is turned on, DaVinci Resolve will use optimized media, when available, to do the final render, to save time. If your media has been optimized to the same format as the one you're outputting to (or better), this is convenient. However, if you've optimized to a lower quality format than what you're outputting to, you should turn this checkbox off to force DaVinci Resolve to process all clips using the original media, guaranteeing the best quality available.
- **Use proxy media:** When this checkbox is turned on, DaVinci Resolve will use the generated proxy media, when available, to do the final render, to save time. However, if your proxies are a lower-quality format than what you're outputting to, you should turn this checkbox off to force DaVinci Resolve to process all clips using the original media, guaranteeing the best quality available.
- **Use render cached images:** When this checkbox is turned on, DaVinci Resolve will write media from the cache to the files being output to save time. If you're caching using the same media format you're outputting to (or better), this can be convenient. However, if you're caching in a lower-quality format than the one you're outputting to, you'll want to turn this checkbox off to force DaVinci Resolve to process all media as it's being rendered, writing at the maximum quality you're outputting to.

- **Force sizing to highest quality:** If you've been working with the "When resizing and scaling:" option set to Bilinear to improve performance when working on slower workstations, turning this checkbox on automatically renders all clips using the "Uses Sharper filter" setting of the Image Scaling panel in the Project Settings.

  For more information, *see Chapter 4, "System and User Preferences."*

- **Force debayer res to highest quality:** When rendering camera raw media formats that allow variable quality debayering, it's common to lower the debayering quality to improve real time performance while grading. Turning this checkbox on guarantees that media will always be rendered at the highest available quality, saving you from forgetting to manually change the debayer setting back when setting up a render at 3am.
- **Render All Video Tracks:** (When rendering Single Clips) You can un-check Render All Video Tracks and select specific tracks in the Disable dropdown menu to exclude those tracks from the final output on a per render job basis.
- **Enable flat pass:** Three options let you choose whether or not to render each clip with its grade applied.

  Off: DaVinci Resolve always applies each clip's grade when rendering.

  With clip settings: For each version of a clip, the system will check that version's pass flat flag. If it's turned on, the system disables color correction for that version of the clip. Otherwise, that version will be rendered with its grade intact. Versions can be individually flagged by right-clicking a clip's thumbnail in the Timeline, choosing the submenu of the version you want to flag, and choosing Enable Flat Pass.

  Always On: When checked, DaVinci Resolve disables the grade of every clip being rendered.

- **Disable sizing and blanking output:** When turned off, Output Blanking to create letterboxing or pillarboxing is "baked" into the output, as are all sizing adjustments made on the Cut, Edit, and Color pages, including Image stabilization.

  When turned on, Output Blanking, Cut and Edit page sizing adjustments, Color page Input and Output Sizing, and Image Stabilization are disabled. Rendered media is rendered either at the source resolution if "Render at source resolution" is enabled in individual clips mode, or to the currently specified resolution of the Timeline or project. If you're outputting via Final Cut Pro or Premiere Pro XML, or Avid AAF, sizing adjustments are output to the XML or AAF files that are created for purposes of round-tripping these adjustments as editable metadata back to an NLE.

  Be aware that "Disable sizing and blanking output" does not disable any transform operations that happen within the Fusion page, nor does it disable transforms happening as a result of an OpenFX or ResolveFX plugin applied to one or more clips in the Cut, Edit, or Color pages. All of these effects will continue to be rendered into the final output.

- **Trigger script at:** You now have the option of triggering a script to execute before or after rendering a timeline, by checking the "Trigger script at" box.

  Start: Executes the script before the render job.

  End: Executes the script after the render job.

  Script: Chooses the specific script to run. You can select the specific script to execute using the corresponding dropdown menu. Scripts must be written for the Resolve scripting framework in either Python or Lua, and placed in the following directory:

  MacOS: /Library/Application Support/Blackmagic Design/DaVinci Resolve/Fusion/Scripts/Deliver/

  Windows: C:\ProgramData\Blackmagic Design\DaVinci Resolve\Fusion\Scripts\Deliver

  Linux: /opt/resolve/Fusion/Scripts/Deliver

- **Render full extents:** (When rendering Individual Clips) When this box is checked, the entire original media clip is rendered out completely, instead of just the portion delineated by the In and Out points of the timeline clip.
- **Add X frame handles:** (When rendering Individual Clips) Lets you specify front and rear handles to be output in frames. This is particularly useful in round trips, when the finishing editor might want additional handles with which to roll edit points or add transitions while fine-tuning the graded edit.
- **Tone Mapping:** (Available in Single clip mode if Dolby Vision or HDR10+ is enabled in Project Settings) When set to None, the timeline is output using the current color management settings. When set to either Dolby Vision or HDR10+, you can choose to output the timeline at a specific peak nit level, color space, gamma, and Data Level using either the Dolby Vision or HDR10+ metadata available to guide the tone mapping operation you've selected. This makes it easy to set up multiple jobs to output HDR outputs at varying levels, as necessary.

DCP and IMF Composition Settings

If you've selected either DCP or IMF from the Format, a Composition Settings group appears with the following parameters when you click the disclosure control, which let you populate generic DCP and IMF composition metadata, as well as various studio specific settings:

- **Composition name:** The name of the exported composition.
- **Issuer:** The organization providing the composition.
- **Use current date:** A checkbox that lets the current date be used as the Issue date automatically.
- **Issue date:** The date the composition is issued.
- **Content kind:** A dropdown provides a list of acceptable choices for defining the content.
- **Content originator:** A text field to add who is responsible for this content.
- **Include volume index and output profile list:** Check this box to include these xml files in the package.
- **Content version label:** Meant to identify the version of the content being provided.
- **Annotate xml using composition name:** Auto-populates Asset Map, Composition Playlist, and Packing List with data from the project. Otherwise these three fields are manually editable.
- **Annotate reel index as suffix (DCP only):** Auto-populates Reel Annotation with data from the project. Otherwise this is manually editable.
- **Annotate media using filename:** Auto-populates Main Video Track and Audio Track 1 with data from the project. Otherwise these three fields are manually editable.

Subtitle Controls

The Subtitle Settings group exposes controls governing how to export subtitles in your program:

- **Export Subtitle checkbox:** Lets you enable or disable subtitle/closed caption output.
- **Format pop-up:** Provides four options for outputting subtitles/closed captions.

  As a separate file: Outputs each subtitle track you select as a separate file using the format specified by the Export As pop-up. A set of checkboxes lets you choose which subtitle tracks you want to output.

  Burn into video: Renders all video with the currently selected subtitle track burned into the video.

  As embedded captions: Outputs the currently selected subtitle track as an embedded metadata layer within supported media formats. There is currently support for CEA-608 closed captions within MXF OP1A and QuickTime files. You can choose the subtitle format from the Codec pop-up that appears.

- **Export As:** (Only available when Format is set to “As a separate file.”) Lets you choose the subtitle/closed captioning format to output to. Options include: IMSC1, DFXP, SRT, and WebVTT.
- **Include the following subtitle tracks in the export:** (Only available when Format is set to “As a separate file.”) A series of checkboxes lets you turn on which subtitle tracks to output.
- **Codec:** (Only available when Format is set to “As embedded captions.”) Lets you choose how to format embedded closed captions; choices include: Text and CEA-608.

NOTE: Neither analog (Line 21) nor digital (CEA-708) closed caption output via Decklink or UltraStudio is supported at this time.

Audio Panel

This panel contains all audio-oriented parameters.

- **Export audio:** Turn this checkbox on to render the source audio, or audio that you’ve synchronized in DaVinci Resolve, along with the media being output by DaVinci Resolve.
- **Format:** You can choose which format of audio you want to render. Depending on which format you choose, different audio codec options will appear below.

  MXF OP1A(IMF): Generates media files that conform to the OP1a (Operational Pattern 1a) SMPTE 378M format of MXF media for file exchange.

  MXF OP-Atom: Generates media files that conform to the SMPTE 390M format of MXF media for file exchange.

  QuickTime: Exposes all available formats of audio compatible with QuickTime.

  MP4: Generates media in the MPEG-4 file format.

  WAVE: Generates media in the WAVE file format.

  MP3: Generates media in the MPEG-3 file format.

  FLAC: Generates media in the FLAC file format.
- **Codec:** Lets you choose between Linear PCM (the default), AAC audio, IEEE Float, or MP3. AAC audio encoding is only available on macOS.
- **Sample Rate:** Lets you set the sample rate, in Hz, of the output of the audio.
- **Bit Rate Strategy:** (Available for AAC encoding) You can choose among Constant Bit Rate, Average Bit Rate, Variable Bit Rate Constrained, and Variable Bit Rate.
- **Quality:** (Available for AAC encoding when Bit Rate Strategy is set to Variable Bit Rate) Five settings you trade between speed and quality when encoding AAC audio.
- **Data Rate:** (Available for AAC encoding when Bit Rate Strategy is set to Constant, Variable, or Variable Constrained) Lets you choose the maximum data rate for AAC encoding.
- **Bit Depth:** Lets you specify the bit depth at which to output the source audio.
- **Render one track per channel checkbox:** This checkbox lets you specify whether you want to export each channel as an individual track in the structure of the exported file. Multi-channel formats can be specified (2.0, 5.1, etc.), or can be output as flat multi-mono files.
- **Render as discrete audio tracks checkbox:** This checkbox is similar to the above, in that it still outputs one channel per track. However, discrete tracks have no positioning info, nor do they group as multi-channel clips (2.0, 5.1, etc.). For example, a mono file exported with Render one track per channel, comes in front and centered. The same file exported as a discrete audio track has no built in position information.

- **Output Track #:** This dropdown menu lets you choose which Main or Submix bus you want to output. A Plus button to the right lets you add additional tracks you want to export in this job, so if you want to export multiple Mains or multiple Subs, you can add more Track pop-ups.

  When you choose a track with multiple channels of audio, a field appears showing how many channels will be output; you have the option of using a virtual slider to change how many channels are output.

  In Single Clip Mode, when you choose "All Timeline Tracks, each audio track in the current timeline will be rendered as an individual track in the rendered media file you're outputting. Multi-channel tracks containing multi-channel clips will output audio tracks containing the same number of channels in the output media, which means you can output mixed combinations of mono, stereo, 5.1 or 7.1, and adaptive audio tracks, and each separately rendered audio track will reflect identical channel mappings.

- **Language:** (Only available when outputting to the IMF format) This dropdown menu lets you choose the language of a particular output track when you're outputting to IMF. Since IMF files can accommodate multiple audio tracks containing different mixes for different regions, it's important to identify each output track you're outputting by language.
- **Content:** (Only available when outputting to the IMF format) This dropdown menu lets you choose the content of a particular output track when you're outputting to IMF. Since IMF files can accommodate multiple audio tracks containing different mixes and content, it's important to identify each output track you're outputting by content.
- **Audio Normalization:** You can select loudness standard presets from the Audio tab in the Render settings on the Delivery page to automatically have the deliverable normalized accordingly. These controls let you control the audio normalization on a per output basis. Unchecking this box bypasses audio normalization and optimization.

  Normalize to Standard: Check this box to normalize loudness or peak (scaling whichever first exceeds thresholds) to a standard.

  Optimize to Standard: Check this box to optimize loudness and peak (ensuring that loudness meets the desired range and peaks remain lower than threshold) to a standard.

  Standard: Choose the normalization standard you want to apply.

  Target Level: Set the normalization level in dBFS.

  Output Track #: Check the box to apply the normalization to these outputs.

File

This panel contains all other parameters.

- **Filename Uses:** Three options let you automatically name the media file(s) that are output automatically.

  Use Custom Filename: Lets you enter your own name in the Custom name/File prefix field.

  Use Timeline Name: (When rendering a Single Clip) When this option is selected, the name of the Timeline is used.

  Use Source Filename: (When rendering Individual Clips) When this option is selected, the filename of each clip's corresponding source media file is cloned, and used as the filename of media being output by DaVinci Resolve. This is preferred when you're generating offline media for use by an editor that you later want to reconform to the originating DaVinci Resolve project. When this checkbox is turned off, you can customize filenames using the other options in this section of settings.

- **Custom name:** Lets you use custom text to name all rendered files. If you're not using the source filename, and not rendering to a file format that uses timecode, you can enter a filename here.

When editing the Custom Name or File Prefix (or File Suffix), you can use “metadata variables” that you can add as graphical tags that let you display clip metadata. This is especially useful when rendering Individual Source Clips.

> For example, you could add the corresponding metadata variable tags %scene_%shot_%take and the File Prefix would be written as “12_A_3” if “scene 12,” “shot A,” “take 3” were in the source clip’s metadata.
>
> For more information on the use of variables, as well as a list of all variables that are available in DaVinci Resolve, *see Chapter 16, “Using Variables and Keywords.”*

- **File suffix:** Lets you add custom text and/or metadata variables (described previously) to the end of all rendered files.
- **Use unique filenames:** (When rendering Individual Clips, and only when Filename uses is set to Custom name) When enabled, additional characters are added to every rendered media file to guarantee that each rendered media file has a completely independent name. This prevents multiple rendered clips from the same source media file from overwriting one another when saved to the same directory. “Uniquely” named clips append the clip name with the track and clip number identifying a clip’s position in the currently selected session. For example, a clip that’s linked to a media file named “DropThatThingCU.mov,” and edited as the twenty-fifth clip on track V2, will be named “DropThatThingCU_V2-0025.mov” when rendered. When enabled, two other options are revealed.

  Use unique filename prefix/Use unique filename suffix: (When Use Unique Filenames is on) Radio buttons let you choose whether to add the unique identifier at the beginning or end of a clip. Choosing Prefix would result in “V2-0025 _DropThatThingCU.mov,” whereas choosing Suffix would result in “DropThatThingCU_V2-0025.mov” when rendered.
- **Add source frame count to filename:** (When rendering Individual Clips, and only when Filename uses is set to Custom name) When enabled, the source frame number of each clip is appended to the end of the rendered file name. This is another way to make sure that multiple rendered clips with custom names don’t overwrite one another.
- **Use filename digits:** Lets you specify how many digits to use when rendering an image sequence, although the specified digits will also be used for any media format. This is particularly useful if you’re outputting media to be used by an application that has strict requirements for image sequence numbering. Defaults to eight digits.
- **Each clips starts at frame:** (When rendering Individual Clips) This permits timecode to be written to the header, and frame count to be written to the filename of the image sequences, which is ideal for VFX workflows.
- **Start timeline timecode at:** (When rendering Single Clip) This option is only available when rendering clips in Single clip order. Specifies the timecode that will be written to the media being output by DaVinci Resolve. For DPX files, timecode is written into the header data, and is simultaneously converted to a frame count that’s inserted into the filename of each frame file, which provides a logical count of the frame numbers. For other media formats, timecode is written to the appropriate metadata container. You may find it useful to use custom start times, for example starting each reel of a project at a particular value, depending on the standards employed at your shop.
- **Place clips in separate folders:** (When rendering Individual Clips) Useful if you need to preserve the filenames of files you’re outputting when the filenames of clips coming from the same source media file may cause them to overwrite one another. This option is also commonly used when rendering VFX shots for additional post-production work, allowing the VFX department to identify clips quickly and distribute the work accordingly.

- **Preserve Source directory levels:** (When rendering Individual Clips) Retains a user-specified depth of the original directory structure used by a clip's corresponding source media file, recreating it when rendering new files for output. The number you select determines how many levels of subdirectories DaVinci Resolve will automatically create within the currently specified "Render job to" directory to match the path used by the source files. Defaults to 0, which creates no matching subdirectories.

  After Head/From Tail: When setting how many directory levels of each clip's file path to preserve (using the "Preserve x levels" parameter), click one of these buttons to specify whether that number of path levels is defined relative to the head or the tail of each media file path.

  Preserved Path: Shows you a preview of the preserved path you've set up so you know you've gotten it right.

- **File Subfolder:** (Only appears in Additional Output panels) Lets you specify a subdirectory into which to render the media files being output. If the specified subdirectory doesn't exist, a new one with that name will be created within the currently specified "Render job to" directory.
- **Use commercial workflow:** (When rendering Individual Clips) Automatically renders every version that's applied to each clip in the session, except for versions that have been flagged using the "Render Disabled" flag, found in the Version submenu for each clip in the Timeline. This option is typically used when you've graded multiple versions of a clip to be used for VFX work, and you want to deliver each grade as a separate media file. This is also used when rendering programs for commercial broadcast where you have two or more versions of a grade for each scene. When using this option, alternate methods of outputting each rendered media file are used, and four additional settings are revealed.

  Alternative pass offset: Lets you separate the timecode values written into each version of a clip with an offset. For example, if the default version timecode is 01:00:20:00, and you select a 10 minute offset in the Alternative Pass Offset timecode entry, then the second graded version of that clip will start at 01:10:20:00, the third version will start at 01:20:20:00, and so on until every version is rendered. You can offset the clips by whatever value you like, but the idea is to make it easy for editors and VFX artists to find the versions of each grade. If the clips are shared with a finishing artist, and they know that each alternate pass is 10 minutes apart, then it's easy for the finisher to change the clip version just by adding 10 minutes to the referenced timecode. To simplify the workflow further, you can put separate source reels in separate folders using the next three options.

  Place reels in separate folders: Automatically places all media that's output using a particular reel name into corresponding folders.

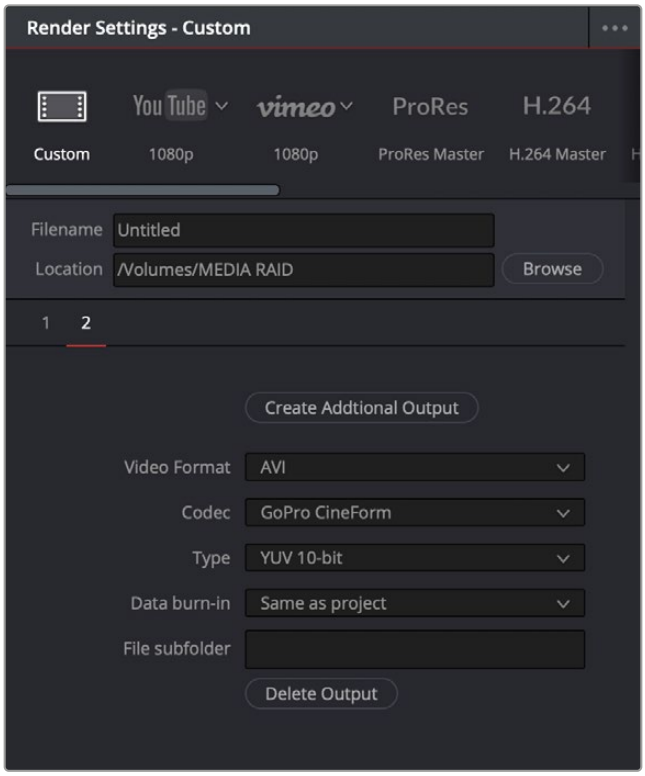
  Place clips in separate folders: Automatically places alternate grades of clips into separate folders.

  Use version name for folders: Labels each folder with the name of the version when using the Commercial Workflow option.

- **Render speed:** A dropdown menu lets you throttle the speed at which media is rendered. Ordinarily you'll leave this set to the default of Maximum. However, some storage systems that are shared by multiple rooms in a facility use storage area networks (SANs) with insufficient bandwidth for multiple real-time image streams. DaVinci Resolve's incredibly fast rendering speeds can cause playback problems with other users accessing the SAN if available bandwidth is insufficient. In this case, you can throttle the render speed to limit SAN bandwidth usage to between 1 to 50 percent of full rendering speed.
- **Disk space currently used:** Shows the amount of disk space available on the target volume.
- **Disk space used after render:** Shows the new disk usage based on the specified range of the current session that you're rendering.

Additional Outputs

Each job you create in the Render Settings defaults to a single output. However, you can create multiple outputs when you need to deliver multiple versions of media, with individual video formats and codecs and different data burn-in settings, to be rendered into individually named subfolders (optional).



The menu command for creating an additional output, shown next to an existing additional output in panel 2

This can be useful for setting up multiple rendered passes when your client requires two sets of media, for example QuickTime ProRes 422 (HQ) media along with MXF DNxHD media. This is also useful when you need to output two sets of media where one has window burns, and the other is clean.

To add additional outputs in the Render Settings:

- Choose Create Additional Output from the Render Settings Option menu. A row of numbers below the Filename and Location controls let you open each output you create and adjust its settings. You can have as many outputs as you require.

To remove an additional output:

- Open the additional output panel you want to remove, and click the Delete button at the bottom.

How to Avoid Overwriting Clips When Rendering Output Media

Three of the options described previously, “Use unique filenames,” “Place clips in separate folders,” and “Use commercial workflow,” are all ways of organizing your rendered media to avoid overwriting rendered clips that happen to share the same file name. These options are necessary because each clip has one logical range of timecode, and because multiple clips often refer to a single source media file with one name.

When rendering a clip, DaVinci Resolve automatically overwrites any other media files that have the same name. So, in instances where you’re trying to preserve the previous filename of the source media file, or where you’re rendering out multiple versions of the same clip, it’s entirely likely that the clips you’re trying to output will overwrite one another, leaving you with the last clip you rendered. The three options mentioned previously prevent this in different ways.

Defining a Range of Clips and Versions to Render

Once you’ve defined the Render Settings, now you need to decide how much of the Timeline you need to render. A Mini-Timeline and Thumbnail timeline are available to help you navigate your project’s clips in order to choose which ones you want to render. Track controls let you enable and disable whole tracks from being output; for example if you need to render a textless version of a timeline in which all the title clips are on track V4, you can disable track V4. Furthermore, you can also use these controls to choose which clip versions you want to render.

To render the entire Timeline:

- Choose Entire Timeline from the Render dropdown in the Deliver page timeline. This option only appears if clips are not filtered.

To disable a video or audio track to exclude those clips from being rendered:

- Click the Video or Audio Disable Track button for the tracks you want to exclude.

To render a filtered subset of clips in the Timeline:

1. Open the Color timeline, if it’s not already shown, and choose an option from the Timeline Filter dropdown to the right of the Clips button in the Interface toolbar.

   The contents of the Thumbnail timeline are restricted to show only the clips matching the selected criteria. For example, if you’ve already rendered a session, but you’ve since made some changes, you can use one of the “Show Modified Clips” options to display only the clips that have changed within a particular timeframe. Another possibility is to choose the “Show Unrendered Clips” option to show all clips that have not yet been rendered.

2. Choose “All Filtered Clips” from the Render dropdown in the Timeline toolbar.

To clear clip filtering:

- Choose All Clips from the Timeline Filter dropdown to the right of the Clips button in the Interface toolbar.

To define a continuous range of clips to render:

1. To define the first clip in the range you want to render, do one of the following:
   - Right-click a clip thumbnail in the Thumbnail timeline and choose Mark In.
   - Position the playhead in the Timeline or the Viewer, and press the I key, or right-click the Timeline ruler and choose Mark In.
2. To define the last clip in the range you want to render, do one of the following:
   - Right-click a clip thumbnail (in the Color timeline) or a clip (in the Edit timeline) in the Thumbnail timeline and choose Mark Out.
   - Position the playhead in the Timeline or the Viewer, and press the O key, or right-click the Timeline ruler and choose Mark Out.

In and Out points appear within the Timeline ruler, and an orange bar shows the range you've selected to render. The In and Out fields update with the first and last frame numbers, in timecode and frame count, and the Duration field updates with the total number of frames you'll be rendering.

IMPORTANT: If you're in Individual Clips mode, In and Out points automatically snap to the nearest clip In or Out point in the Timeline. You cannot render partial clips in Individual Clips mode, but you may do so in Single Clip mode.

To render a single clip:

- Open the Thumbnail timeline if it's not open already, Right-click any clip thumbnail, and choose Render This Clip.
- An orange bar in the Timeline ruler shows that clip is selected for rendering. If you need to render several clips individually, you can select each clip one at a time to add as individual jobs to the Render Queue.

Choosing Which Versions to Render for Each Clip

By default, the currently selected version that was set in the Color page is rendered for each clip. If you want to render a different version, the easiest thing to do is to make sure they're selected on the Color page Timeline before you open the Deliver page.

However, a Versions submenu, within the Thumbnail timeline's contextual menu for each thumbnail, also provides options to manage grade versions. These commands are duplicates of options that are available from the Thumbnail timeline of the Color page.

To choose which version to render:

- Right-click any clip thumbnail in the Thumbnail timeline, and choose a version from the Versions submenu.

TIP: You can right-click a clip in the Thumbnail timeline of the Color or Render screen and rename any version of a grade. This can assist a facility's workflow when sharing material between suites and applications.

Using the Render Queue

Once you've defined the settings necessary to render the type of media you require, and the range of the current session you want to render, you need to add all that information as a job to the Render Queue. You can add as many jobs to the Render Queue as you need, depending on what files you need to output.

Each job can have individually specified ranges of clips and individual clip settings, which can include different render directories, different formats, resolutions, data levels, burn-in settings, and so on. As a result, you can use the Render Queue to queue up the render of multiple sections of the current session, or multiple versions of the same media. Furthermore, you can queue up multiple sessions, if you have several differently graded sessions.

To add a job to the Render Queue:

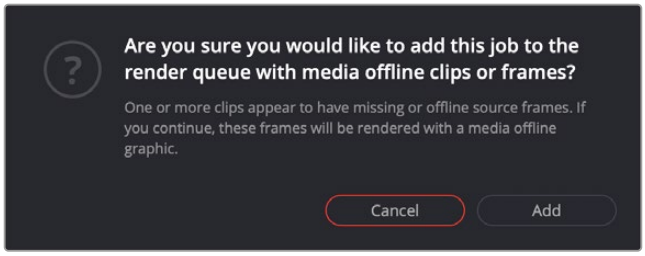
1. Select a timeline.
2. Choose the settings you require in the Render Settings, using one of the Presets, or by choosing your own custom settings.
3. Choose a range of clips to render using the Deliver page Timeline using the procedures described in the previous section.
4. Click the Add to Render Queue button at the bottom of the Render Settings.
5. If you haven't chosen a location for the render yet, you'll be prompted to do so now via a File Destination dialog, so choose a location and click Ok. If there's already media in the render location you've specified, you may also see a dialog telling you "This render may overwrite existing clips in this folder." If you want to continue, click Yes, otherwise click No.

That render setup is now added as a job to the Render Queue, showing the project and timeline name, and location path where the render will be written to.

A selected job in the Render Queue

Media Offline Warning in Render Queue

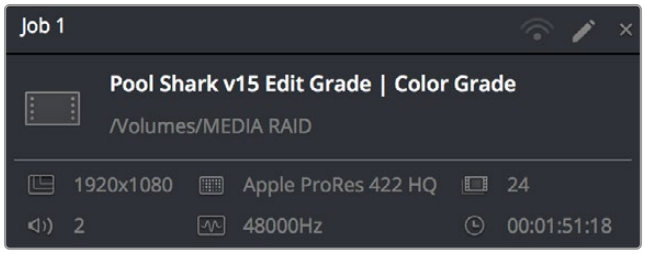
When you attempt to add a job to the Render Queue with a timeline that contains any offline material, DaVinci Resolve automatically gives you a warning. You may choose to either cancel adding the job, or to add it anyway, knowing you're about to render one or more offline clips.



Media Offline warning box that appears if your timeline contains offline clips or frames and is added to the Render Queue

To show more details about jobs in the Render Queue:

Click the Render Queue Option menu (at the upper right-hand corner) and choose Show Job Details. Each job now lists the frame size, format, frame rate, audio channels and sample rate, and duration below the name and location path.



A selected job in the Render Queue with job details shown

To rename a job:

Jobs can be given custom names simply by clicking on the default job name (Job 1, Job 2, and so on) and typing a new name of your own. This can be useful for setting up jobs that you may be re-rendering over and over as you work on a project.

To start rendering:

1. If you want to restrict rendering to only selected jobs in the Render Queue, then select one or more jobs by clicking on one, and then Command-clicking on others to choose discontinuous jobs, or Shift-clicking on another to select an entire range of jobs. When you select one or more jobs, only the selected jobs will be rendered. If no jobs are selected, then all jobs in the queue will be rendered.
2. Click the Start Render button, underneath the Viewer to the right of the interface.
3. If there are jobs in the Render Queue that have already been rendered, a dialog will appear asking "Selected items contain already rendered items. Do you want to re-render them?" Clicking Yes will re-render all jobs in the Render Queue. Clicking No only renders the jobs that have not yet been rendered. Clicking Cancel cancels the entire rendering operation.

   Rendering begins, starting with the highest job in the list. The Overall Progress bar starts to fill up, from right to left, indicating how much of what's been queued up has been rendered so far. While rendering is in progress, the Start Render button changes to the Stop Render button, which can be clicked at any time to halt rendering.

> **TIP:** While rendering is in progress, a small progress bar will appear on the DaVinci Resolve icon in the dock of Mac OS X, or on the taskbar of Windows.

To remove jobs from the Render Queue, do one of the following:

- **To clear a specific job:** Click the X at the upper right-hand corner of a job's entry in the Render Queue.
- **To clear all previously rendered jobs:** Click the Render Queue Option menu (at the upper right-hand corner) and choose Clear Rendered.
- **To clear all jobs:** Click the Render Queue Option menu (at the upper right-hand corner) and choose Clear All.

To change a job that has been rendered to appear unrendered again:

Right-click any rendered job, and choose Clear Render Status. You can also select multiple jobs to change their rendered status all at once. This makes it easy to re-render the exact same job.

To edit a job that has or has not been rendered:

1. Click the Pencil button in the Render Queue to select it.

Clicking the pencil icon to edit a job in the Render Queue

The selected Render Queue's settings repopulate the Render Settings list, and resets the selected range of the Timeline corresponding to that job.

2. Change whichever settings you need to.
3. When you're finished editing the job, click the Update Job button that appears at the bottom of the Render Settings, or you can click Add New Job to create a new job with the changes you've made, leaving the previous job untouched.

NOTE: If you click the Pencil button again without clicking Update Job, you'll be prompted to Save, Cancel, or Don't Save.

To review clips that correspond to rendered jobs:

- **To show a rendered clip in the Media Storage browser:** Right-click any rendered job, and choose Reveal in Media Storage.
- **To show a rendered clip in your computer's file system (Mac OS only):** Right-click any rendered job, and choose Reveal in Finder.

Rendering Jobs from Multiple Projects at Once

You can also add multiple projects from the currently open PostgreSQL or local project library to the render queue all at once. This can be exceptionally useful in situations where you've broken a program into multiple reels, with each reel being a different project.

To render output from multiple projects at once:

1. Open each project, set up whatever jobs you want to render in the Render Queue, and save that project without rendering.
2. When you've set up the last project, click the Render Queue Option menu (at the upper right-hand corner) and choose Show All Projects.

   All queued items in projects belonging to the currently selected user (if using a network project library) or in the currently specified disk location (if using a local project library) now appear in the Render Queue.
3. Click Start Render to begin rendering every job from every project in the queue.
4. When you're finished, turn Show All Projects off to go back to displaying only the current project's render queue items.

Remote Rendering

If you have multiple DaVinci Resolve workstations on the same network, you can send a job in the Render Queue from the workstation you're using (referred to as the "artist workstation") to one of the "remote workstations" on the network using remote rendering. This lets you use any one of your currently unused secondary workstations to render your jobs, while you continue working on your main workstation.

In order to use remote rendering, you must adhere to the following three criteria:

- Both the artist workstation and the remote workstation must have DaVinci Resolve Studio installed. Remote rendering does not work with the free version of DaVinci Resolve.
- Both the artist workstation and the remote workstation can use the same shared network project library, or any other Postgres project library that is connected to either one of the machines, or to a dedicated Remote Project Library Server.

  For more information on setting up and using shared project libraries, *see Chapter 192, "Managing Project Libraries and Project Servers."*

- Both the artist workstation and the remote workstation must have access to the same media files on either the same storage volumes, or identically named storage volumes.

Using Multiple Project Libraries in Remote Rendering

You can set up remote renders for projects in all connected Davinci Resolve project libraries, not just the currently active one. To activate this feature, check the "Automatically scan other project libraries for Remote Rendering jobs" box in the General settings of the System tab, of the DaVinci Resolve Preferences.

Sharing Storage

It's important that both the artist and remote workstations have access to the same media on the same named storage volume for remote rendering to work properly. This can be done via some manner of shared storage, such as a SAN. However, it can also be done by mounting the same volume over your network. This will be slower, but it will work.

If you're mixing Mac OS X, Windows, and Linux workstations for remote rendering, you'll need to use the Mapped Mount column of the Media Storage Locations list in the Media Storage panel of the System Preferences to add each volume's path as it's understood on the workstation it's attached to. For example, on a Windows workstation that's accessing volumes from a Linux workstation, type in the Linux-style file paths in the Mapped Mount column for each scratch disk that's listed.

Setting Up and Using Remote Rendering

Using remote rendering is easy, but it does require a bit of preparation.

1. Make sure the storage volume containing the media being referenced by the project you want to render is mounted on both the artist and remote workstations.
2. Open DaVinci Resolve on the remote workstation, and do one of the following:
   - When the Project Browser opens, right-click anywhere and choose Remote Rendering.
   - If you've already opened a project in DaVinci Resolve, you can also choose Workspace > Remote Rendering.

DaVinci Resolve will automatically open to the Deliver page, awaiting jobs to be assigned for automatic rendering.

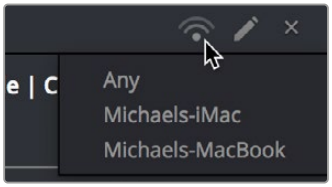
3 On the artist workstation, add a job to the render queue as you normally would.

4 Click the Remote Rendering button for that job in the Render Queue and one of the options from the list that appears:

Any: Automatically assigns that job to the next workstation that isn't currently rendering anything. If all remote rendering workstations are rendering, assigns it as the next job in line.

YourComputer.local: The artist workstation with the name "YourComputer." Choose this if you want to render the job locally, and not remotely.

Other Workstations on Network: All other remote rendering workstations are listed below, so you can choose which specific workstation you want to assign a job to.



Clicking the Remote Render button to remotely render a job

5 Click Start Render. The job is sent to the remote workstation you selected and is rendered, while you're free to continue working on your artist workstation.

When You're Finished Remote Rendering

Once you're done using a particular DaVinci Resolve workstation in Remote Rendering mode and you want to go back to using it as an artist workstation, choose Workspace > Remote Rendering to exit remote rendering and return to the Project Manager.

Setting Up a "Headless" Remote Rendering Workstation

DaVinci Resolve allows remote rendering clients to operate in a so-called "headless" mode, with no GUI. This can be accomplished from the command line, by opening the directory where the app is located and then running DaVinci Resolve in Remote Rendering (–rr) mode using the correct command line syntax for your operating system. Once run in this way, DaVinci Resolve silently and invisibly waits on that system for remote rendering jobs to be sent to that workstation.

On macOS

Open Terminal.

Change the directory to:

```
cd /Applications//DaVinci\ Resolve/DaVinci\ Resolve.app/
Contents/MacOS/
```

Run the following command:

```
./Resolve -rr
```

On Windows

Open the Command Prompt.

Change the directory to:

```
C:\Program Files\Blackmagic Design\DaVinci Resolve\
```

Run the following command:

```
Resolve.exe -rr
```

On a Linux CentOS 6.8 system

Open Terminal.

Change the directory to:

```
cd /home/resolve/Cyclone/
```

Run the following command:

```
./script.start -rr
```

On a Linux CentOS 7.x system

Open Terminal.

Change the directory to:

```
cd /opt/resolve/bin
```

Run the following command:

```
./resolve -rr
```

Chapter 185

Delivering DCP and IMF

For projects requiring Digital Cinema Package (DCP) or Interoperable Master Format (IMF) mastering for digital cinema or broadcast distribution, DaVinci Resolve allows native DCP and IMF encoding and decoding for the creation and playback of unencrypted DCP and IMF deliverables, or it can be integrated with Fraunhofer's easyDCP application in order to master fully encrypted DCP files, play them back for testing, and generate Key Delivery Messages (KDMs) for theatrical distribution, all directly within DaVinci Resolve.

This means you can encode a DCP or IMF master straight from your program's source media, all within the 32-bit floating point image processing pipeline of DaVinci Resolve, for the highest possible quality result.

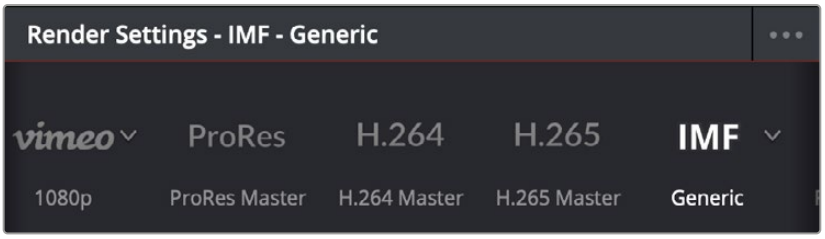
Native IMF Encoding and Decoding (Studio Version Only)

The Format dropdown in the Video panel of the Render Settings now has a native IMF option that lets you export to the SMPTE ST.2067 Interoperable Master Format (IMF) for tapeless deliverables to networks and distributors. No additional licenses or plugins are required to output to IMF.

The IMF format supports multiple tracks of video, multiple tracks of audio, and multiple subtitle and closed caption tracks, all of which are meant to accommodate multiple output formats and languages from a single deliverable. As of DaVinci Resolve 16, IMF export also supports exporting IMF packages that use ST.2098 and Dolby immersive audio via selected Main busses. All of this is done by wrapping a timeline's different video and audio tracks (media essences) and subtitle tracks (data essences) into a "composition" within the Material eXchange Format (MXF).

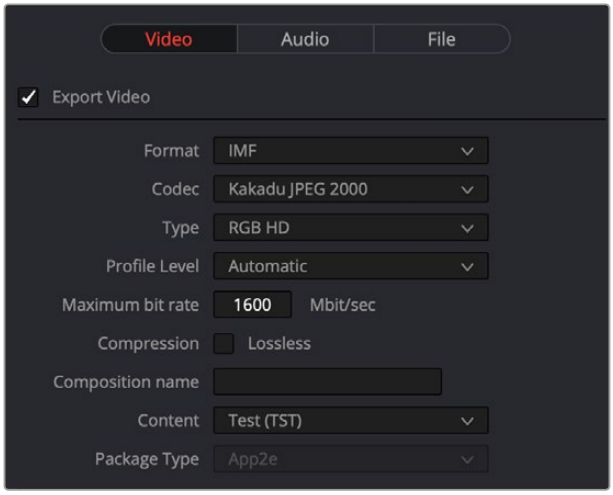
Additionally, a dropdown menu to the right of this preset provides options for Generic, 20th Century Fox, and Netflix versions of this preset.



The IMF Generic preset in the Render Settings has options for different resolutions of output

When IMF is selected from the Format dropdown, the Codec drop-down menu presents options for Kakadu or EasyDCP encoding, with Kakadu being the method that's included with DaVinci Resolve Studio. A Type dropdown lets you choose what kind of JPEG2000 output you want, with options including RGB, YUV, and Dolby Vision. Additional parameters include:

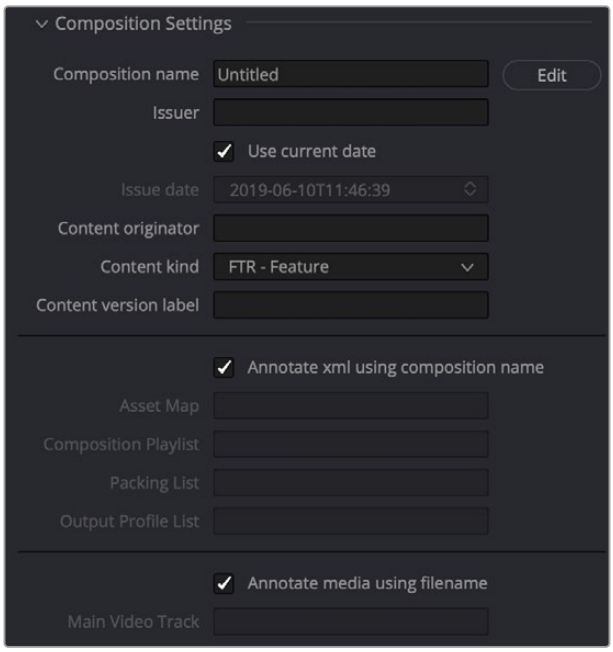
- **Package Type:** Defaults to App2 Extended (App2e), for encoding JPEG 2000 up to 4K.
- **Bit Depth:** The bit depth of the encoded IMF video.
- **Encoding Profile:** A dropdown that lets you choose among Auto, IMF, and Broadcast.
- **Encoding Level:** Provides different choices based on what is selected in Encoding Profile.
- **Maximum bit rate:** Lets you choose how much to compress the result.
- **Lossless Compression:** Lets you choose to encode using lossless compression.
- **Slope-Rate Control:** A checkbox lets you specify lossless compression.
- **QStep:** (DCP, IMF) Lets you choose either automatic or manually specified DCP quantization levels at which to compress the video signal when using the Kakadu JPEG 2000 encoder.



Render settings in the Export Video section for the IMF format

A separate group of parameters named Composition Settings, underneath the Advanced Settings, lets you add metadata to your IMF package, including:

- **Composition name:** The name of the exported composition.
- **Issuer:** The organization providing the composition.
- **Use current date:** A checkbox that lets the current date be used as the Issue date automatically.
- **Issue date:** The date the composition is issued.
- **Content kind:** A dropdown provides a list of acceptable choices for defining the content.
- **Content version label:** Meant to identify the version of the content being provided.
- **Annotate xml using composition name:** Auto-populates Asset Map, Composition Playlist, and Packing List with data from the project. Otherwise these three fields are manually editable.
- **Annotate media using filename:** Auto-populates Main Video Track and Audio Track 1 with data from the project. Otherwise these three fields are manually editable.



Parameters for adding composition metadata

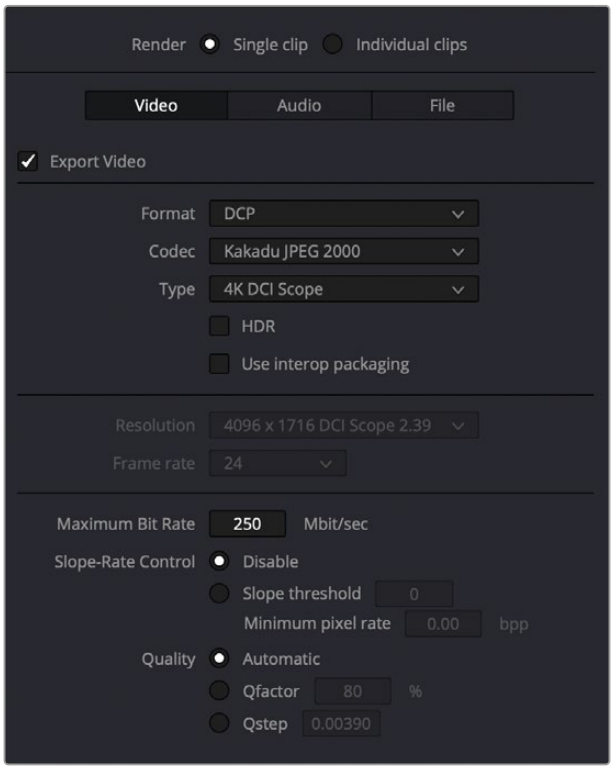
Native Unencrypted DCP Encoding and Decoding (Studio Version Only)

DaVinci Resolve also has native DCP encoding and decoding support built-in, for unencrypted DCP files only. That means that you can output and import (for test playback) unencrypted DCP files without needing to purchase a license of EasyDCP. If you have a license, a setting in the Configuration panel of the System Preferences enables you to choose whether to use EasyDCP (for creating encrypted DCP output), or the native DaVinci Resolve encoding.

Native DCP Encoding Parameters

When you choose DCP from the Format dropdown menu, the following additional parameters are exposed:

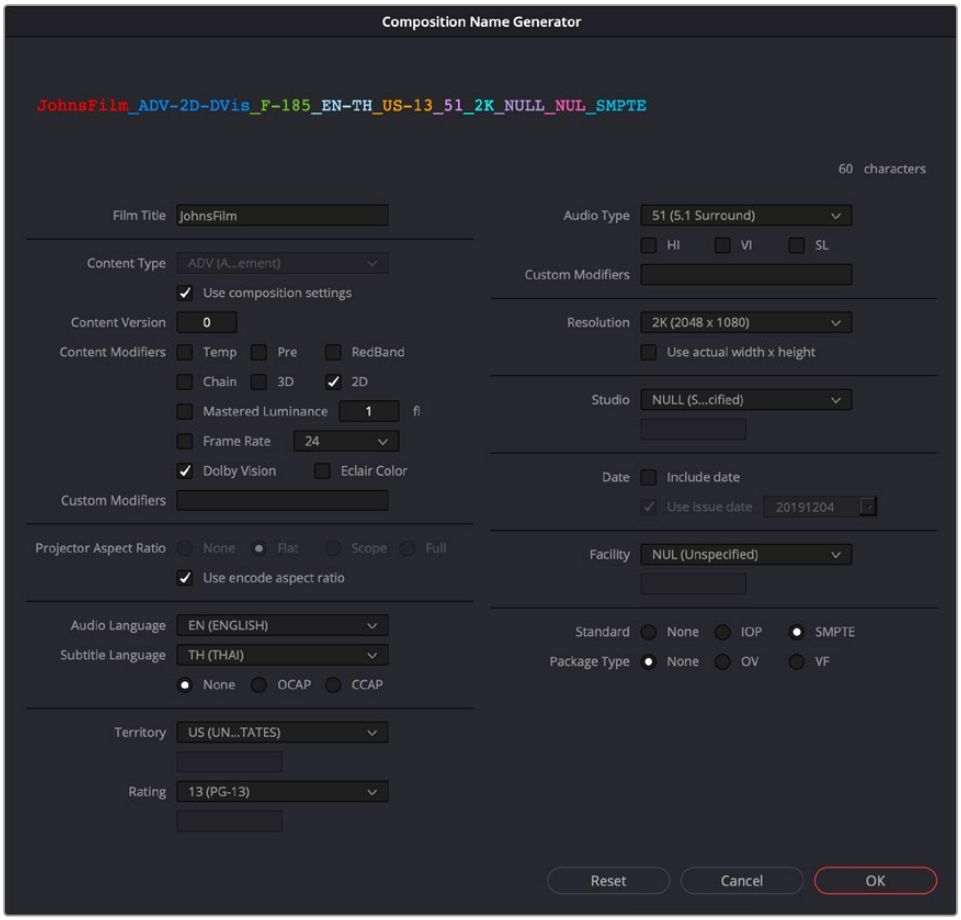
- **HDR:** (DCP, IMF) Specifies the package as having HDR content.
- **Use interop packaging:** (DCP only, located under Type parameter) Lets you create an Interop DCP package, based on an earlier standard of DCP delivery that is not forward compatible with SMPTE DCP packages.
- **Maximum bit rate:** (DCP, IMF) Lets you choose how much to compress the result.
- **Lossless Compression:** (IMF) Lets you choose to encode using lossless compression.
- **Slope-Rate Control:** (DCP, IMF) A checkbox lets you specify lossless compression.
- **Quality:** (DCP, IMF) Lets you choose either automatic or manually specified DCP quantization levels at which to compress the video signal when using the Kakadu JPEG 2000 encoder.



Native DCP settings in DaVinci Resolve

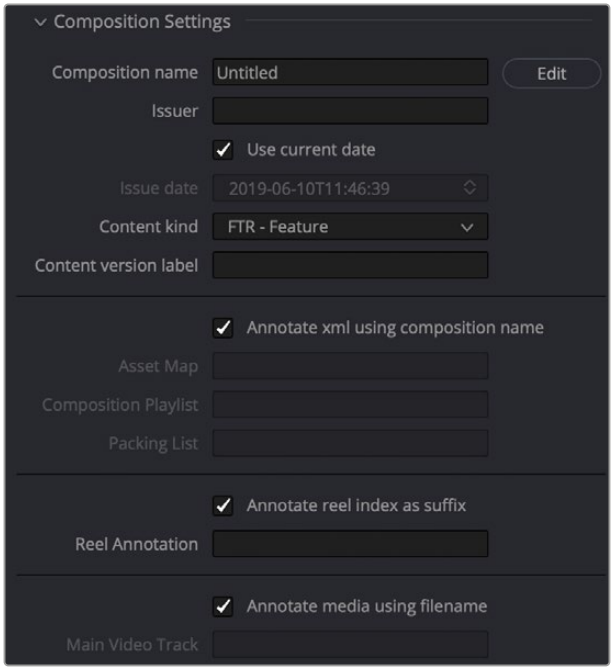
If you've selected DCP from the Format dropdown menu, a Composition Settings group appears with the following parameters when you click the disclosure control, which let you populate standard DCP composition metadata:

- **Composition name:** The name of the exported composition. DCPs use specific naming conventions for the composition name that include metadata about the file itself for DCP projectors and playback equipment. DaVinci Resolve has a tool called the Composition Name Generator to generate these names properly for you; it is accessed by pressing the "Edit" button next to this field. Simply fill out the fields and press OK, and DaVinci Resolve will rename your composition in line with these standards.



The Composition Name Generator will pass a standards compliant name for you to the Composition Name field.

- **Issuer:** The organization providing the composition.
- **Use current date:** A checkbox that lets the current date be used as the Issue date automatically.
- **Issue date:** The date the composition is issued.
- **Content kind:** A dropdown provides a list of acceptable choices for defining the content.
- **Content version label:** Meant to identify the version of the content being provided.
- **Annotate xml using composition name:** Auto-populates Asset Map, Composition Playlist, and Packing List with data from the project. Otherwise these three fields are manually editable.
- **Annotate reel index as suffix:** Auto-populates Reel Annotation with data from the project. Otherwise this is manually editable.
- **Annotate media using filename:** Auto-populates Main Video Track and Audio Track 1 with data from the project. Otherwise these three fields are manually editable.



Parameters for adding composition metadata

Rendering IMF Segments and DCP Reels

DaVinci Resolve supports splitting IMF and DCP projects into separate segments and reels, in addition to rendering media as a single file. This can be useful for breaking up your timeline to fit within allowed file sizes on legacy file systems, separating marketing and studio assets from the final film, or just being able to replace certain sections of the film without having to re-encode the entire file.

To Render an IMF Segment or DCP Reel:

1. Choose IMF or DCP from the format settings in the Video tab of the Render Settings panel.
2. Navigate to the “Segment list” or “Reel list” section of the composition settings.
3. Choose from the following options:

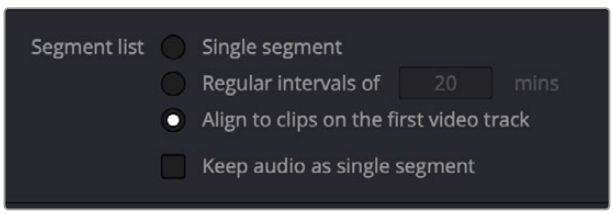
   Single segment/reel: Encodes the Timeline into a single file (default setting).

   Regular intervals of: Encodes the Timeline into multiple segments/reels, each one the duration of the value set in the “mins” field.

   Align to clips on the first video track: Encodes the Timeline into multiple segments/reels; each individual clip on the V1 track of the Timeline becomes its own separate file.

   Keep audio as single segment (IMF only): Select this checkbox to keep the audio portion of the IMF as a single file, regardless of the segment options selected above.

4. Press the Add to Render Queue button.



IMF Segment options

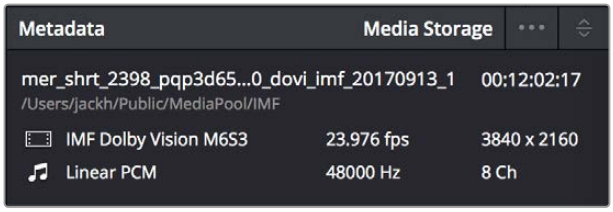
Creating DCP/IMF Supplemental Packages

Once created, DaVinci Resolve has the ability to reimport a DCP or IMF so that you can overwrite parts that need to be updated with new media, in order to export a “Supplemental Package,” which is effectively a new version of the program that combines the new overwritten parts of the program with the old version, such that you can deliver just the changes.

NOTE: Supplemental packages are only supported using the Kakadu encoder and decoder; this is not compatible with DCP or IMF packages created using EasyDCP. To avoid issues, disable “Use easyDCP decoder” in the Decode Options panel of the DaVinci Resolve System Preferences.

Importing a DCP or IMF Into a Timeline

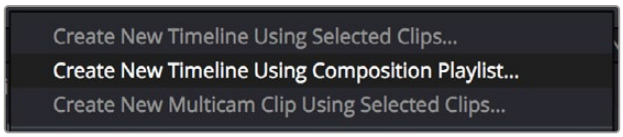
1 Using the Media Storage browser in the Media page, find and select the DCP or IMF, and check the header of the Metadata Editor to verify that your media is suitable for creating a supplemental package. Supported IMF profiles will be displayed in the Metadata Viewer.



The header in the Metadata Editor showing an IMF that’s compatible with the creation of a supplemental package

2 Create a new project and add the DCP/IMF package you need to modify to the Media Pool. If a dialog appears asking if you want to change your timeline frame rate to match the incoming media, click Change to make your project match the media.

3 Create a timeline from the composition playlist (XML) within the imported DCP or IMF by right clicking the imported package in the media pool and choosing “Create New Timeline Using Composition Playlist” from the contextual menu.



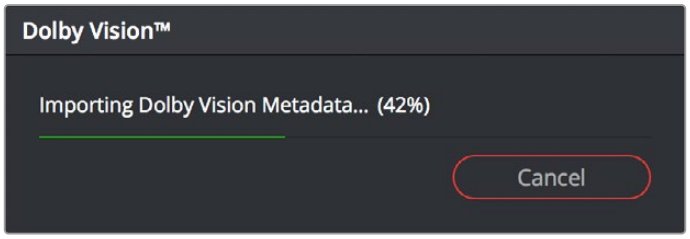
Right-clicking an imported IMF or DCP clip in the Media Pool reveals a command to make a new timeline using the composition playlist in the contextual menu

4 The New Timeline dialog has an “Import Dolby Vision Project Settings” checkbox. When it’s turned on, clicking Create will do the following:

a) Dolby Vision will be enabled in the Color Management panel of the Project Settings, and the Mastering Display menu will be set to match that of the IMF package.

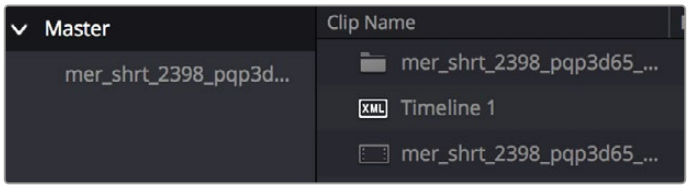
b) If Resolve Color Management (RCM) is not active, the Timeline Color Space will be set to match the Dolby Vision metadata. However, if RCM is already enabled, the user must manually set this by turning on “Use Separate Color Space and Gamma,” and changing the Timeline settings to P3-D65” and “ST.2084” respectively.

5 Creating the Timeline will import Dolby Vision metadata (if applicable). This will allow a Tone Mapping preview to be seen on the Color page that uses the original metadata.



Dolby Vision metadata will be imported if present when importing an IMF

Once import is complete, all video and audio clips from the DCP or IMF appear within a new bin with the name of the package. The resulting timeline will be identified via its icon as a DCP/IMF timeline.

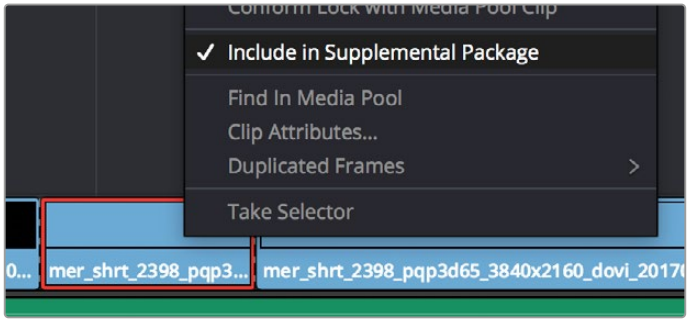


The imported media and timeline when you import an IMF

Editing the Resulting Timeline

At this point, you can edit the program in the Timeline as necessary.

- You can overwrite sections of the Timeline with new clips. All modifications will be automatically included into the supplemental package.
- You can use the Blade tool or Insert Edit command to cut sections of the existing program to which you want to add Fusion effects, audio grading, or color correction. When you do this, you must right click that section and choose “Include in Supplemental Package” to make sure it exports correctly.



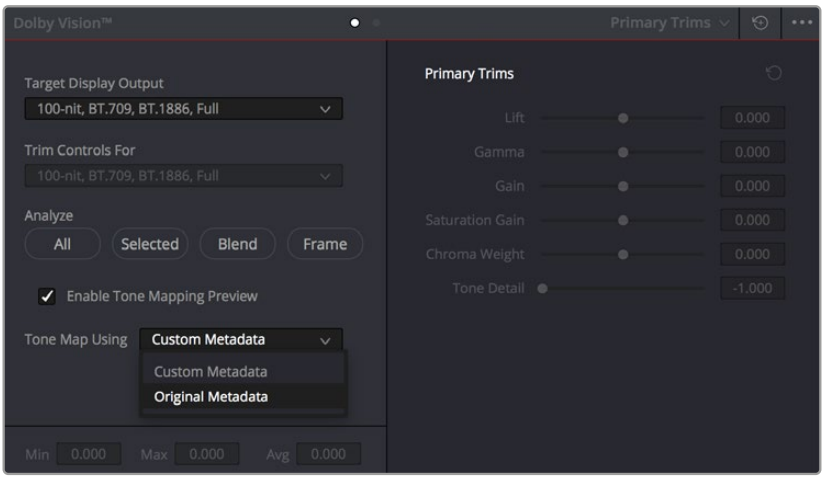
Right-clicking a section of the program and choosing Include In Supplemental Package

For IMF Dolby Vision packages, please ensure all modifications are on the first video track (V1).

NOTE: If RCM is being used, please ensure the input color space and gamma of the inserts are correct.

Dolby Vision Metadata

The Dolby Vision metadata from the imported DCP/IMF file can be reused by selecting “Original Metadata” from the Tone Map Using dropdown menu of the Dolby Vision palette in the Color Page

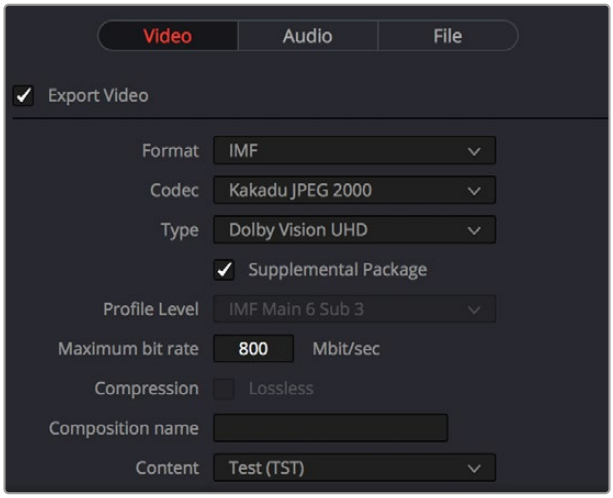


Setting a clip to Original Metadata in the Color Page

Alternatively, this metadata can be imported separately from an existing XML via the “Import Metadata from XML” command in the option menu of the Dolby Vision palette in the Color page. When successful, “Imported Metadata” will be enabled.

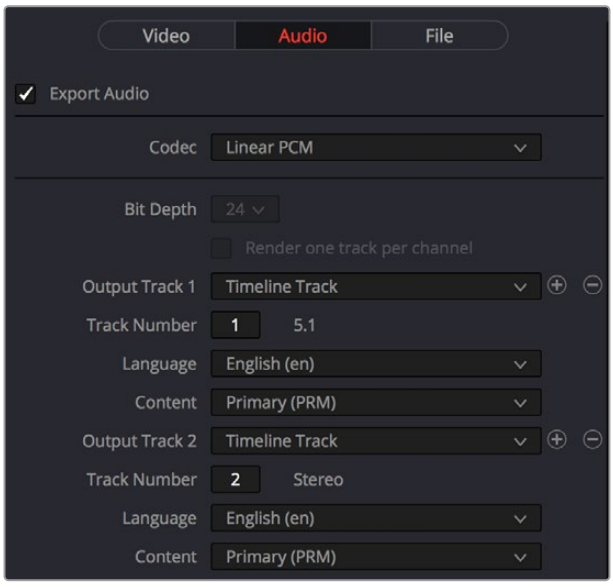
Exporting

You can export a supplemental package by turning on “Supplemental Package” in the the video panel of the Deliver page Render Settings list.



Setting an export to be a Supplemental Package

The codec type and profile will be automatically selected to match the original version of the DCP/IMF package, and the audio tracks are set to match the Timeline tracks. Please ensure the rest of these audio settings are matched to the original version, since they start out set to the default values.



Setting the audio settings of a Supplemental Package export

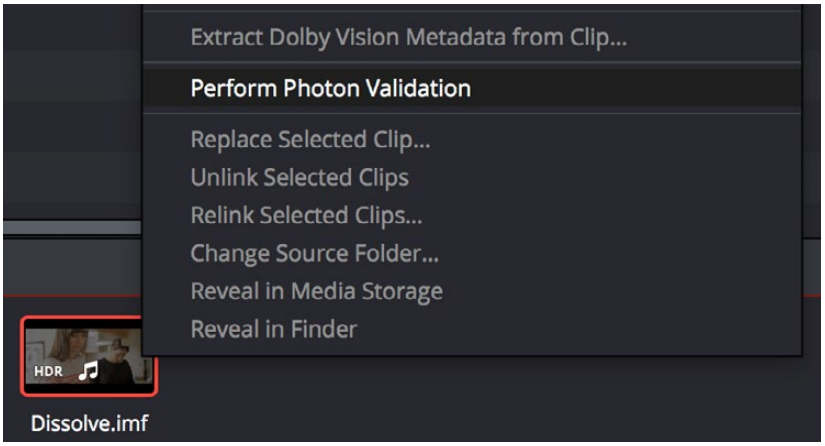
Photon Validation of IMF Packages

Photon is Netflix's validation software for IMF App2/App2e packages. The option for using Photon validation will only be shown on Resolve Studio with JDK/JRE version 1.8 and above installed, which is available at https://github.com/Netflix/photon.

NOTE: Please disable "Use easyDCP decoder" from "Preference" as there can be issues decoding IMF packages without an easyDCP license.

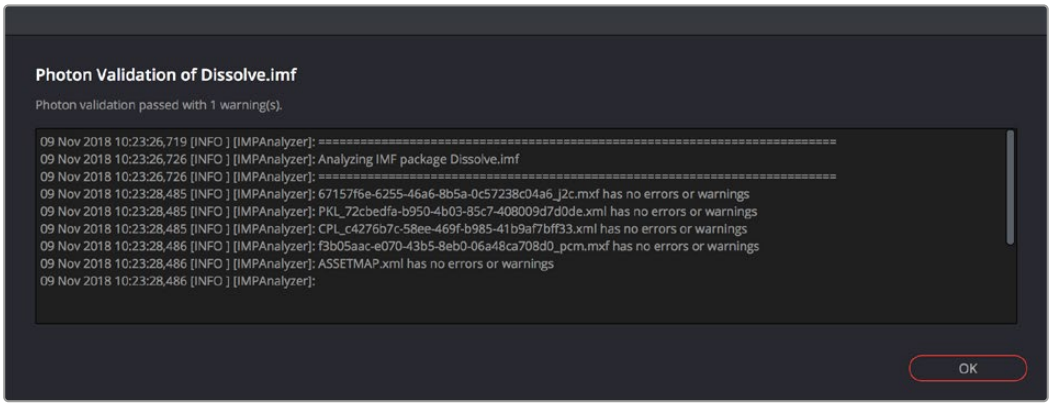
Validating in the Media Pool

An existing IMF package can be validated with Photon by importing it into the Media Pool, then right-clicking it and choosing "Perform Photon Validation" from the context menu.



Validating an IMF in the Media Pool

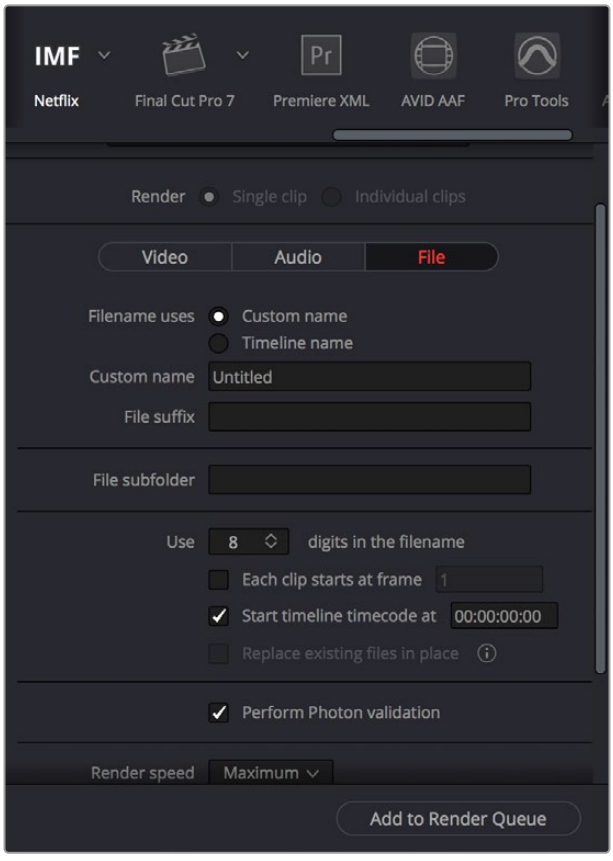
A report dialog will be shown when the validation is completed.



A validation report

Validating on Export

Photon validation can be enabled in the File panel of the Deliver page Render Settings; choosing the “IMF Netflix” preset will also enable this option. When enabled, DaVinci Resolve will perform Photon validation after the IMF package is exported. The validation report will be saved to a text file in the IMF package folder, and a report dialog will be shown if there is any error.



Enabling Photon validation on export

Using and Licensing EasyDCP

Both DaVinci Resolve and DaVinci Resolve Studio include a demo version of easyDCP. Details of operation and restrictions of the demo version can be found later in this chapter. The fully functional version of easyDCP operates via licensing modules purchased from http://www.easyDCP.com (info@easyDCP.com) and every new DaVinci Resolve system (server) needs its own license and specific certificates for DCP and KDM generation and for playback of DCPs.

Requesting Your Server Certificate Set

For your DaVinci Resolve system to generate DCPs and KDMs you need to request a specific set of configuration files called the Server Certificate Set. To begin, first purchase your encoding, encryption, decoding, and decryption modules from easyDCP. They will provide a password to access your easyDCP account.

Then, from the DaVinci Resolve File menu, select easyDCP > Request Server Certificate Set. Fill in the detail listed on the request form and save the form to your desktop or somewhere it can be easily found. This html file can be emailed to info@easyDCP.com. After sending the html, a customized Server Certificate Set for your installation will be generated and made available for download in your easyDCP Website User Account.

The Server Certificate Set generated for your DaVinci Resolve will contain files based on your purchased modules and your specific DaVinci Resolve server hardware. The table below shows the modules and the licenses and certificates generated, followed by a brief description of each item.

	License	Server Certificate	Signer Certificate
DCP Encoder	X		X
DCP Encoder with Encryption	X	X	X
DCP Player	X		
DCP Player with Encryption	X	X	

- **License:** The License is used to activate the purchased modules on a specific hardware server.
- **Server Certificate:** Each DCP render (referred in the industry as an “Instance”) using encryption or decryption has an individual server certificate. This certificate is required to be able to receive Key Delivery Messages (KDMs), which unlock encrypted DCPs.
- **Signer Certificate:** A Signer Certificate is used to sign certain files within a DCP package and/or Key Delivery Message (KDM) to verify which authority generated the DCP instance.

Importing Your Server Certificate Set

Once generated and downloaded to your DaVinci Resolve server, the Server Certificate Set needs to be imported into DaVinci Resolve.

To import your server certificate:

1. Choose File > easyDCP > Import License and Certificates.
2. Use the Import Server Certificate dialog to select the file, enter your Certificate Set password, then click Import.
3. To verify your easyDCP license and the Server Certificates, choose easyDCP > About easyDCP.

From this point onward, you can use the controls from within the Settings window, the Deliver page, and the File menu to master and play DCPs.

Limitations of the Demo Version of easyDCP

The demo version of the DCP encoder embeds visible DaVinci Resolve and easyDCP logo watermarks in the rendered Digital Cinema Package (DCP) images. The demo version does not include encryption so these DCPs can be used for screening in a digital equipped cinema. The demo version of the DCP playback module will play 15 seconds in full quality. After that playback quality reduces drastically. Furthermore, audio won't be rendered after 15 seconds of playback.

Switching Between Native DCP and EasyDCP Encoding

A checkbox in the Configuration panel of the System Preferences, "Use EasyDCP Encoder," lets you choose whether to use the native DCP/IMF encoding in DaVinci Resolve, or your licensed EasyDCP software. In either case, all set up happens from within the Deliver page of DaVinci Resolve.

EasyDCP Color Management

The Color Management panel of the Project Settings has a Timeline Colorspace dropdown menu that is enabled for EasyDCP encoding regardless of whether or not DaVinci Resolve Color Management is used for the current project (the same setting is used for both color management tasks). You should set this to the color space used by your current DaVinci Resolve timeline. If, for example, you are grading using a Rec. 709 monitor for television deliverables but also wish to make a DCP, select Rec. 709 Gamma 2.4 and DaVinci Resolve will render the DCP with the correct Rec. 709 to XYZ matrix.

EasyDCP Output in the Deliver Page

To master to a DCP in the Deliver page, use the following procedure, which walks you through all of the easyDCP settings that are available in the Render Settings list.

To master a DCP or IMF:

1. Set "Render timeline as" to Single clip.
2. Choose easyDCP from the Video Format dropdown.
3. Choose the appropriate option from the Codec dropdown that corresponds to the type (DCP or IMF) resolution (2K or 4K), and aspect ratio (native, scope, or flat) of your intended output.
4. Set the Composition Name. This field is intended to hold a standardized name for the DCP being encoded. You can either type a name into this field directly, or you can press the "..." button to open the easyDCP Composition Name Generator window. An editable Film Title field appears, along with a number of dropdown menus that let you select various DCP attributes such as content type, aspect ratio, language of audio and subtitles, and so forth. As you populate each attribute, the name being generated appears at the top of the window, and clicking OK copies the resulting Composition Name into the Composition Name field of the Render Settings.

5 If necessary, set the desired “Maximum DCP bit rate” by either typing or dragging within the field (the range is 50 to 250 Mbit/sec). If you’re not sure what data rate to use, consult the client or distributor to whom you’re delivering the DCP.

6 There are two DCP package types you can output, determined by the “Use Interop packaging” checkbox:

- The standard package conforms to the “Interop” specifications for DCPs, which is turned on by default. With “Use Interop packaging” turned on, however, the frame rate of your output is limited to either 24fps or 48fps, so you need to make sure that your timeline conforms to these frame rates.
- If you want to generate DCP packages with other frame rates to match your timeline, you need to turn “Use Interop packaging” off to generate a SMPTE-standard DCP. This supports additional frame rates including 25, 30, 50, and 60 fps. However, SMPTE-Standard-DCPs are not supported on all JPEG2000-based playback systems so it’s generally recommended to use the Interop standard unless you know the player supports the SMPTE-Standard DCPs.

7 Turn on the “Encrypt package” checkbox to encode an encrypted DCP. This sets the encoder to generate a Digest containing the keys used during encryption. This Digest will allow you to play the resulting DCP on your system, and to generate KDMs to allow that DCP to be played on other servers.

> **NOTE:** If you do not encrypt the DCP it can be played on any DCP player/decoder without restriction.

8 Set the Subtitles Path. If you have a properly formatted subtitle file, click the Browse button to link to it.

9 If you’re including an audio mix in the DCP, go to the Audio section, turn on the Render audio checkbox, and choose the number of channels in the “Render channels of audio” dropdown menu that corresponds to the number of Audio Mixer output channels defined in the Edit page.

10 Click the Browse button under the “Render to” field, and choose a location for the resulting DCP. Make sure you pick a drive with enough room for the estimated size of the final DCP.

11 Choose all necessary options from the Output Options to ensure the quality you need.

12 Click the Add Job to Render Queue button, and then click Start Render to create your DCP. A DCP will be created and placed at the location you chose, ready for playback or delivery.

KDM Generation and Management

Key Delivery Messages (KDMs) are required to allow an encrypted DCP play on a designated projector at a particular theater at a specified time. DaVinci Resolve is capable of creating KDMs, which is convenient for exporting KDMs for select screenings, but commercial distributors may require thousands of KDMs. Fortunately, easyDCP allows you to use external Distribution KDM (DKDM) utilities to generate KDMs for your clients, so you don’t have to tie up your DaVinci Resolve workstation with this task.

Publishing Your Encrypted Digital Cinema Package

While you can play your encrypted DCP on the same DaVinci Resolve system that generated it, if you wish to publish the DCP so other players can decode and play you need to generate a KDM to send to the player. The user of the other player, or players, will need to generate a Server Certificate for each of their players and send this to you so when you generate the KDM it will be just for those players.

Select the DCP in the Media page Library. Right-click and select Generate KDMs. From the dropdown select the location of the Server Certificate file if the KDM is for one player, or folder for multiple players. Set the start and end dates that the KDM will be valid for, an output folder to place the KDM, and then select Generate.

You can now send your DCP and the KDMs to the player you authorized. The user there will import the KDM and the DCP will play between the start and end dates.

Playing Your Digital Cinema Package

To play a DCP you've output from DaVinci Resolve, use the Media page to add it to the Media Pool and edit it into a timeline like any other clip.

Decoding the JPEG2000 images embedded within the DCP in real time is computationally intensive. If your system is underpowered you can reduce the decoded resolution of the files by selecting Half or Quarter Resolution Decode from the File > easyDCP menu. A smaller, less bandwidth-intensive version of the JPEG2000 files will be decoded by discarding some levels of the wavelet stage inside the decoder, which will directly increase the playback performance.

Playing Third-Party Digital Cinema Packages

To play a non-encrypted DCP simply select the DCP in the Media page like any other clip. To play an encrypted DCP from a third party you first must publish your Server Certificate. They use the certificate to generate KDMs for their DCP to play on your DaVinci Resolve system. From the File menu choose easyDCP > Export Server Certificate, and on the dropdown menu choose a location to save the file. Send this to the third party for KDM generation.

When you receive a KDM or a Digest for an encrypted DCP you must first import the file into your DaVinci Resolve system. Choose File > easyDCP menu > Import KDM/Digest, and then select the file. Then simply select the encrypted DCP in the Media Page Library to play.

Chapter 186

Delivering to Tape

This section covers how to use the Deliver page to output a timeline, either in whole or in part, to a device-controllable VTR connected to a compatible Blackmagic Design video interface.

For whichever output interface you use, you need to make sure that the RS-422 interface is connected to that of the VTR, and that device control has been established.

The Tape Output Interface

Tape output is accomplished on the Deliver page, which has to be placed in the Tape mode before you can proceed.

To switch to tape output in the Deliver page:

- Click the Tape button, which is the third button from the left on the Interface toolbar at the top of DaVinci Resolve. The Deliver page updates to reflect the relevant controls for editing to tape.

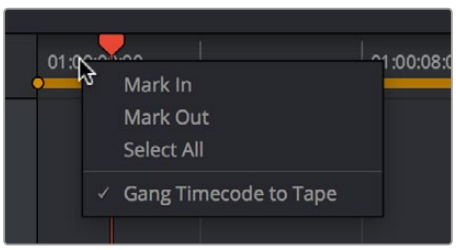
While in Edit to Tape mode, the Deliver page is used to control the VTR, in order to establish In and Out points for insert or assemble editing of the selected portion of the current Timeline to tape.

- **Capture and Playout:** The Render Settings panel turns into the Capture and Playout panel, with controls and settings governing how DaVinci Resolve will output your program to tape.
- **Edit to Tape Queue:** The Render Queue turns into the Edit to Tape Queue, which lets you set up a batch of either previously rendered media files, or In and Out point-defined segments of the current Timeline for simultaneous output to tape.
- **Transport controls:** The transport controls, while similar in appearance to those used while in Render mode, now control the VTR.
- **Shuttle control:** A shuttle control appears in what was formerly the jog or scrubber bar, which lets you shuttle through the range of reverse and forward speeds compatible with that deck.
- **In and Out controls:** In Edit to Tape mode, the In and Out buttons to the right of the transport controls define a range of the tape to Insert or Assemble edit to, within the current Timeline. While in Edit to Tape mode, you can still define In and Out points to define a specific range of the Timeline by right-clicking a clip in the Thumbnail or Mini-Timeline, and choosing Mark In or Mark Out. You can only add In or Out points to the beginning and end of clips.
- **Cue In and Cue Out controls:** Buttons next to the timecode In and Out fields cue the tape to those frames on tape.

Edit to Tape controls

Gang Timecode to Tape

When the Deliver page is in Tape mode, you can right-click the ruler running along the top of the Timeline and choose “Gang Timecode to Tape,” which puts DaVinci Resolve into a mode where every time you set an In point on the Deliver page Timeline, a corresponding In point is automatically set on the tape deck. Setting both In and Out points on the Deliver page Timeline results in the In and Out points on the tape deck being set at the same timecode, making it easy to set up insert edits to tape on top of a previously output program.



The Gang Timecode to Tape option

Insert/Assemble Dropdown Menu

A dropdown menu under the In and Out buttons lets you choose how to edit the selected part of the Timeline to tape. There are two options:

- **Insert:** Performs an insert edit to tape, in which selected tape tracks are seamlessly and frame-accurately overwritten without interrupting the timecode or control track. You must be outputting to either a blacked tape, or a prerecorded tape to make an insert edit.
- **Assemble:** Performs an assemble edit, in which every track of tape is overwritten, including the video, audio, timecode, and control tracks.
- **Crash:** (Only appears if "Output Source Timecode" has been enabled in the Playout section of the Capture and Playback panel of the Project Settings) Similar to an assemble edit, except there is no pre-roll period to let the VTR get up to speed. A crash edit also overwrites every track of the tape, including the video, audio, timecode, and control tracks, and may result in a more visible jump at the resulting edit point. However, in some instances crash edits may be the only option for a particular operation.

NOTE: When DaVinci Resolve is performing a Batch Output operation, you can only output clips using assemble editing or crash recording.

Start Record Button

Once you've set In and Out points to define how much of the tape to record to, the Start Record button initiates device-controlled tape output.

Setting Up for Tape Output

Before you perform an edit to tape, the Capture and Playback panel of the Project Settings has a number of options that you should set to match the format and type of tape output you're doing.

General Options

The Output LTC checkbox, when turned on, directs DaVinci Resolve to output LTC timecode.

Capture and Playout Settings

These settings affect both capture and playback when using the Tape Ingest options of the Media page, or the Tape Output options of the Deliver page.

- **Video capture and playback:** You can choose the video format (frame size and frame rate) with which to output to tape from this dropdown menu. HD timelines can be downconverted to SD, and SD timelines can be upconverted to HD using the format conversion of your DeckLink card.
- **Use left and right eye SDI:** A checkbox that enables supported video interfaces to ingest and output muxed stereoscopic video when used with supported VTRs, such as HDCAM SR decks with 4:2:2 x 2 mode. (When muxed stereoscopic signals are ingested, each eye is separated into individual left-eye and right-eye image files.) This parameter only appears when your hardware is set up appropriately.
- **Video connection operates as:** Selects between the available signal options: Use 4:4:4 SDI, and enable Single Link. Which options are available depend on which video capture card you are using.

- **Data Levels:** Lets you specify the data range (normally scaled or full range) that's used when ingesting from or outputting to tape. This option switches the data range of the signal output by your video capture card, but only during capture from tape in the Media page, or output to tape in the Deliver page. When capture or output is not currently occurring, your video capture card goes back to using the identically named data range setting in the Master Settings panel of the Project Settings, which governs how you monitor the signal being output on an external broadcast display or projector.
- **Video bit depth:** Choose the bit depth that corresponds to the capability of your deck. You can choose between 8-bit and 10-bit. Outputting to 10-bit is more processor intensive, but higher quality for compatible devices, and is the default setting.
- **Use deck autoedit:** If supported by your video deck, this is the best method to record video to the deck, as it enables the deck to roll the edit using the specified preroll, and control the edits via serial device control. If this checkbox is turned off, a basic edit On/Off mode is used by the deck, with the potential for frame inaccuracies if the "Non auto edit timing" setting is not properly adjusted.
- **Non auto edit timing:** Adjusts the edit synchronization of the connected deck when auto edit is turned off.
- **Deck preroll:** Sets the number of seconds for preroll. How much is appropriate depends on the performance of your deck.
- **Video output sync source:** When using a DeckLink card this is set to Auto. Other capture cards may require you to set the sync source to "Reference" for playout and "Input" for ingest. This setting is only available if you have a DVS card installed on your system.
- **Add 3:2 pulldown:** Inserts or removes the 3:2 pulldown required to record or play 23.98 fps media to or from a 29.97 tape format.

Capture

These settings are used when you use the Capture mode in the Media page to capture clips from tape into the Media Pool. Media is captured as DPX image sequences.

- **Capture:** Lets you choose whether to capture both Video and Audio, or Video Only.
- **Video Format:** The format that scanned film frames are saved as. When capturing from tape, the available options are DPX and QuickTime. When capturing from the Cintel film scanner, this is restricted to Cintel Raw Image (CRI), which is a raw data format that DaVinci Resolve automatically debayers as a Cineon log-encoded image for grading.
- **Codec:** The codec used to write captured media. When capturing from tape, these include the various type of Apple ProRes, 8- and 10-bit YUV 422, 10-bit RGB, and the various types of DNxHD. Cintel Raw Image files default to RGB.
- **Save clips to:** A field that displays the directory path to which media files captured from tape are written. You want to choose a volume that's fast enough to accommodate the data rate of the media format you're capturing.
- **Browse:** Click this button to choose a directory to write captured media to. The directory you choose appears in the field above.
- **Save in this folder path:** A series of checkboxes let you specify what other information to use to define the directory hierarchy that will hold the captured media. Every checkbox you turn on adds an additional directory with a name defined by that checkbox's metadata. You can choose any or all of the following: Program name, Clip number, Reel number, and Roll/Card.
- **Apply reel number to:** Lets you choose how to write the reel name. Two checkboxes let you write the reel number to the file's name, and/or to the Header data.
- **Use prefix:** A field lets you type in a prefix to be used in the media file's name. This lets you add text identification that will make the media more easily identifiable and searchable.

- **Apply prefix to:** Two checkboxes let you choose to use the prefix you typed in the file name, and/or in the folder name.
- **Use frame number with:** When capturing to image sequences, you can choose how many digits to use when writing the frame number into the name of each frame file.
- **Set batch ingest handles to:** When capturing to image sequences from a batch list, defines how many frames of additional handles to ingest along with each logged clip.
- **Enable audio input:** Turn this checkbox on to capture audio along with the video. If you're capturing QuickTime or MXF files, the audio will be written as additional tracks inside each file. If you're capturing to a DPX image sequence, then a broadcast .wav file is recorded separately.
- **Input:** Lets you choose how many tracks of audio to capture, from 2 to 16.

Playout Settings

These settings only affect the video signal that's output when you use the Edit to Tape mode of the Deliver page.

- **Output:** Lets you choose whether to output both Video and Audio, Video Only, or Audio Only if you're doing an audio layback.
- **Output Source Timecode:** Turn this checkbox on to output each individual clip's source timecode. This option is only applicable when assemble editing to tape.
- **Output LTC:** With a Blackmagic Design DeckLink or UltraStudio device using HD-SDI, longitudinal timecode (LTC) is available on track 16 of the HD-SDI video signal, making it easy to use a Mini Converter de-embedder to extract this analog timecode audio signal and feed it directly to a recording device. This is particularly helpful if you have outboard video processing equipment such as a noise reducer or format converter that does not pass through the VITC timecode.
- **Delay LTC by x frames:** When outputting LTC to bypass outboard processing gear, such as a noise reducer or format converter, you can compensate for the processing delay by delaying the timecode by a matter of frames to ensure that the processed image and timecode reach the deck at the same time. With a DVS card there is a separate timecode output.
- **Enable audio output:** When this checkbox is enabled, DaVinci Resolve will play all available timeline audio along with the video being output, so both can be recorded to tape.
- **Offset audio by x frames:** Lets you specify an offset between the audio track and video to achieve proper A/V sync in cases where the video is being delayed by outboard processing hardware.
- **Output x channels of audio:** Choose the number of audio tracks to output to tape.
- **Set batch playout head handle to x seconds:** When batch outputting multiple clips, you can specify a number of frames before the In point of each clip to be output as well.
- **Set batch playout tail handle to x seconds:** When batch outputting multiple clips, you can specify a number of frames after the Out point of each clip to be output as well.
- **Apply gaps between clips:** This checkbox lets you add a black gap, of the specified duration in frames, between every two clips being output when outputting in batch mode.

Edit to Tape Queue Option Menu Settings

The following settings and options are available in the Option menu found at the top right-hand corner of the Edit to Tape Queue.

- **Show Job Details:** Lets you see more information about each job listed in the Render Queue.
- **Clear Recorded:** Clears all queue items that have already been output to tape.
- **Clear All:** Clears every queue item.

- **Sort by Reel & Timecode:** Does a multi-criteria sort by reel and timecode, reel first, then timecode.
- **Sort by Timecode:** Sorts by timecode only.
- **Output Source Timecode:** Sets tape output to write source timecode to tape (each clip's individual timecode), rather than record timecode (from the Timeline).
- **Use Preview for Tape Output:** Enables Preview mode when outputting to tape. Preview mode lets you test how an edit to tape operation will work before actually recording it.

Tape Output Procedures

There are a few different ways you can output media to tape, depending on what you need to accomplish, and on how intensive your grades are relative to the processing capabilities of your workstation.

Power Mastering

Power Mastering allows you to select either a range of clips, or an entire timeline, to be output to tape in real time, without rendering. This can save you from a time-consuming render, and it also saves disk space. Power Mastering is a no-compromise procedure, since your program is still output at full quality.

If there are a handful of clips with grades that you know are too processor-intensive to be Power Mastered, you can use the Render Cache controls to cache the problem clips before output.

For more information, *see Chapter 8, "Improving Performance, Proxies, and the Render Cache."*

Outputting a Program From the Timeline

The simplest method of outputting to tape is to output a single Timeline, either in its entirety, or in part if you're insert editing a small section that has been revised.

To Power Master to tape:

1. Use the Render Cache, if necessary, to cache any clips that are too processor-intensive to output in real time.
2. Click the Edit to Tape mode button to the left of the transport controls to switch to tape output.
3. Define how much of the current Timeline to output by moving the playhead throughout the program, and then right-clicking clips that define the beginning and end of the range you need to output and using the Mark In and Mark Out commands.
4. Use the transport controls to find the In point on tape at which you want to start recording, and click the In button.
5. Choose Insert from the dropdown menu at the upper right-hand side of the Viewer, if you're either outputting to a striped and blacked tape, or inserting over an existing program on tape.
6. Click the Power Mastering (lightning bolt) button at the bottom of the tape settings to add the job you've just set up to the Edit to Tape Queue.
7. Click Start Record to begin the process of outputting to tape. Device control is used to record to the designated section of tape; a progress bar appears at the bottom of the Render Queue to show how long this will take.

If you don't want to Power Master, you can render the section of the Timeline you need to output as a single clip first, as a self-contained media file, and then add that clip directly to the Edit to Tape Queue. This might be an easier solution if you're outputting an extremely processor-intensive timeline.

To output a pre-rendered media file to tape:

1. Click the Add Clips button at the bottom of the tape settings, and use the VTR Record dialog to select the media file you rendered in step 1, and click Add Clip(s) to Queue.

   The media file you selected is added to the Edit to Tape Queue as a Power Mastering job, and will be output in its entirety.
2. Use the transport controls to find the In point on the tape at which you want to start recording, and click the In button.
3. Choose Insert from the dropdown menu at the upper right-hand side of the Viewer, if you're either outputting to a striped and blacked tape, or inserting over an existing program on tape.
4. To preview what the edit will look like before actually writing it to tape, choose "Use Preview for Tape Output" from the Edit to Tape queue option-menu, and then click Start Record to watch DaVinci Resolve run through the edit using the deck. After previewing the edit, turn this setting off.
5. Click Start Record to begin the process of outputting to tape. Device control is used to record to the designated section of tape; a progress bar appears at the bottom of the Render Queue to show how long this will take.

Batch Outputting Multiple Clips

You also have the option of outputting a number of clips to tape in a batch operation, as opposed to outputting from the Timeline. When you set up a batch of multiple clips in the Edit to Tape Queue, then DaVinci Resolve will automatically record them sequentially to tape.

How the timecode is generated during batch output depends on the "Output Source Timecode" setting in the Capture and Playback panel of the Project Settings. If this is turned off, then a continuous timecode track will be written to cover everything being output to tape. If this is turned on, then each clip's source timecode will be written to tape discontinuously.

When batch outputting to tape, you can add black handles to each of the clips to space them out, making later ingest easier, using the "Set batch playout head/tail handle" settings in the Capture and Playback panel of the Project Settings.

To make a Batch Record multiple clips to tape:

1. Use the transport controls to find the In point on tape at which you want to start recording, and click the In button.
2. Do one of the following to add items to output to the Edit to Tape Queue:
   - Click the Add Clips button at the bottom of the tape settings, and choose one or more media files from the VTR Record browser, and click Add Clip(s) to Queue.
   - Right-click any clip in the Timeline, choose Render This Clip, and then click the Power Mastering button at the bottom of the tape settings to add that clip to the Queue.
3. Choose either Assemble or Crash from the dropdown menu at the upper right-hand side of the Viewer. Because you're outputting clips with discontinuous timecode, you cannot insert edit when batch outputting.
4. Once you've added all the clips you want to output to the queue, click Start Record to begin outputting to tape. Device control is used to record to the designated section of tape; a progress bar appears at the bottom of the Render Queue to show how long this will take.

Chapter 187

Exporting Timelines to Other Applications

Once you've completed editing and grading a program, you may need to export your final graded timeline as EDL, AAF, XML, or OTIO files in order to send it to another application for further finishing, effects work, or to complete a round trip from an NLE.

To send a graded project to another application, you need to render the graded clips first using the controls on the Deliver page to render the Timeline as individual source clips. In this mode, the reel name and timecode metadata of each rendered clip is mirrored by the exported project file, to maintain the correlation between exported EDL, XML, AAF, or OTIO data and the rendered media. For detailed information about rendering in the Deliver page, *see Chapter 184, "Rendering Media."*

If you render using the Easy Setups that correspond to Final Cut Pro XML or Avid AAF round trips, then an XML or AAF will be exported to the same directory you've rendered to. However, you can still export an XML, AAF, or EDL file separately should the need arise.

Alternately, if you've edited a project from scratch in DaVinci Resolve and need to move a timeline to another application, you can export any timeline to any format for purposes of project exchange, without the need to render new media (depending on your workflow).

Even in situations where you've imported a timeline from another application, the robust project compatibility of DaVinci Resolve makes it possible to import one type of project exchange file, such as XML, and then export a completely different kind, such as AAF or EDL. This lets you use DaVinci Resolve as a project exchange utility.

Exporting Timelines from DaVinci Resolve

Modern post-production is not a one-stop process. It's a common need for timelines and assets to be moved between many different applications from a multitude of companies. While DaVinci Resolve has its own proprietary .drt format for use in passing timelines between DaVinici Resolve workstations, the program also offers a robust toolset for moving your assets to many other popular applications.

As of this writing, the most reliable way to pass DaVinci Resolve timelines between applications is as follows:

- **From DaVinci Resolve to/from another DaVinci Resolve workstation:** Export/Import a DaVinci Resolve Timeline file (.drt)
- **From DaVinci Resolve to/from another application:** Export/Import an OpenTimelineIO file (.otio, .otioz), if supported. If not supported, fall back to using XML or AAF flies instead.

Exporting to OTIO

DaVinci Resolve supports the Open Timeline IO (.otio) format for importing and exporting timelines between applications. OTIO is an open source media and timeline interchange format created by the Academy Software Foundation. It's designed to be application and platform agnostic, allowing you to pass your timeline and its media assets between programs with more compatibility than AAF or XML.

There are two different OTIO formats supported by DaVinci Resolve:

- **.otio:** These files contain just the metadata about the timeline and no associated media. They are small, portable, and require the end user to link the timeline to their own copies of the media.
- **.otioz:** These bundle files contain both the timeline metadata and all of the timeline's media assets zipped together into one file. As a result, this file can be very large, as it contains the full length media files of all assets used in the timeline. However it assures that whoever imports the file has all the media needed and is linked automatically to replicate the timeline on their machine without error.

To Export an OpenTimelineIO (.otio, .otioz) file:

1. Select File > Export > Timeline (Shift-Command-O).
2. Type in a name for the timeline file.
3. In the file browser select either .otio files or .otioz bundle files in the format selector.
4. Click Save.

NOTE: If you selected to export .otioz bundle files, an additional step of creating the OTIO bundle will occur as it adds each complete media file from all clips in the timeline to the final bundled file. This can take a long time and may need additional storage based on the length and amount of media assets used.

Exporting to AAF/XML

Whether you've edited your project from scratch inside of DaVinci Resolve, or you're doing a round trip with an application that uses AAF, Final Cut Pro 7 XML, or Final Cut X XML project exchange formats, you can export any DaVinci Resolve timeline in the Edit page to any project format DaVinci Resolve supports. Whatever your workflow, keep the following in mind:

- **Timelines are automatically exported when you render a timeline in the Deliver page:** When you use the "Final Cut Pro Round-Trip" or "Avid AAF Round-Trip" render setting presets, or a preset created from one of them, a corresponding XML or AAF file is automatically exported along with the media you render.
- **Even if you've imported a project from another application, you can re-edit imported projects before export:** If necessary, you can freely re-edit projects you're planning to export. When you export an AAF or XML file, the Timeline will be sent back to the originating NLE, or onward to the finishing application of choice.
- **Unsupported effects are sometimes preserved in Round Trip workflows:** If there were effects or clip constructs in the original sequence that were not compatible with DaVinci Resolve, how those effects will be handled depends on the project format you're exporting to, and whether or not you've edited the project. For XML projects, unsupported effects are saved internally by DaVinci Resolve, and are exported with the XML file that you output no matter what. Consequently, they should reappear when you reopen the exported file in the originating NLE. For AAF projects, you can export unsupported effects as long as you don't re-edit the project. However, if you do re-edit the project, then you can only export an AAF file that's been stripped of all unsupported effects.
- **Project formats can be converted to other formats:** Using DaVinci's Export commands, compatible project formats can be converted from one format to another. For example, an imported EDL can be output as Final Cut Pro X XML. For that matter, Final Cut Pro 7 XML can be imported and then exported as Final Cut X XML. Or, an AAF file from Media Composer can be imported and then exported as a Final Cut Pro XML file to be opened in any NLE or finishing application compatible with that format, such as Premiere Pro or Smoke.

To export an AAF or XML file after you've rendered the graded clips:

Do one of the following:

1. To export the current Timeline, choose File > Export AAF, XML, or press Shift-Command-O.
   - Open the Edit page, right-click the Timeline you want to export in the Media Pool, and choose Timelines > Export > AAF/XML.
   - When the Export XML dialog appears, type a name for the file and choose a location for the exported XML file, then click Save.
2. An XML version of that timeline is saved, complete with references to the graded media you rendered, and is ready for import into an NLE or finishing application.

More About Exporting to AAF

When you export to AAF, there are actually two options that are available to you, depending on whether you made editorial changes to the Timeline in the Edit page:

- **If you didn't make any editing changes to the Timeline you imported:** You can choose File > Export AAF, XML, and choose "AAF Files" from the Format dropdown menu. This exports all audio and effects using data from the original AAF file that was exported from Media Composer, regardless of whether or not they're supported in DaVinci Resolve. When you export an unedited AAF, DaVinci Resolve uses the Avid AAF file that you originally imported to create an updated one; make sure it's still in the same location as it was when you first imported it into DaVinci Resolve.
- **If you made editing changes to the Timeline you imported, or you're exporting a project that wasn't AAF to begin with:** Then you need to right-click the Timeline you want to export in the Media Pool and choose Timelines > Export > Generate New AAF. This option creates a brand new AAF file, but audio and effects that are not supported in DaVinci Resolve in an AAF import are discarded.

Exporting an EDL

DaVinci Resolve is also capable of exporting EDLs that can be reimported into other applications.

> For more information about EDL workflows, *see Chapter 24, "Ingesting From Tape." see Chapter 56, "Conforming and Relinking Clips."* and *Chapter 60, "Conforming EDL Files."*

To export an EDL:

1. Open the Edit page and select the Timeline you want to export an EDL from in the Media Pool.
2. Exported EDLs only have a single video track. For timelines with multiple tracks, only the events on the video track with the destination control assigned to it will be exported (the destination control is the first control at the left in the track header). If you want to export a track other than Video 1, you can assign the destination control to the specific track you need to export.
3. Right-click the Timeline in the Media Pool, and choose Timelines > Export > AAF/XML/EDL from the contextual menu.
4. When the Export Timeline dialog appears, type a name, choose a location for the exported EDL, and choose EDL Files from the dropdown menu at the bottom, then click Save. An EDL is exported.

Exporting a Missing Clips EDL

This command lets you export a quick report listing all clips that are offline in the currently selected track of the Timeline in the Edit page. This report is in EDL format, with one event for each clip that's offline, which describes the reel number and source timecode of the missing media, as well as the record timecode of the missing media's position on the Timeline.

Here's an example of an exported Missing Clips EDL:

```
TITLE: ( no title )

1   A001_C002_0820GA_001 V    C  10:28:27:03   10:28:28:00   01:00:00:00   01:00:00:21

2   A004_C012_0820MC_001 V    C  14:07:31:21   14:07:35:13   01:00:12:13   01:00:16:05

3   A017_C001_0820CV_001 V    C  21:16:14:22   21:16:15:00   01:00:16:05   01:00:16:07
```

Once you've exported this information, you can hand it off to whomever can help you track down the missing media.

To export a Missing Clips EDL:

1. Open the Edit page and open the Timeline you want to export a Missing Clips EDL for in the Timeline browser.
2. For timelines with multiple tracks, only the events on the video track with the destination control assigned to it will be examined for missing clips. If you want to examine a track other than Video 1, you can assign the destination control to the specific track you need to examine for missing clips.
3. Right-click the Timeline in the Media Pool, and choose Timelines > Export > Missing Clips EDL from the contextual menu.
4. When the Save Missing Clips EDL dialog appears, type a name and choose a location for the exported EDL, then click Save.

Exporting Timeline Markers to EDL

If you keep notes about a project within the notes field of Timeline markers, found in the Timeline ruler, then it's possible to export those notes as an EDL.

To export timeline markers as an EDL:

1. Right-click that timeline in the Media Pool, and choose Timelines > Export > Timeline Markers to EDL.
2. Choose a location and export format from the Export Edit Index dialog, and click Save. Each Timeline marker is listed in the resulting EDL, with any notes included along with a duration, where applicable.

Exporting to CDL

DaVinci Resolve can export and import basic grading data to and from other applications via a Color Decision List (CDL). CDLs are an industry-standard file format originally developed by the American Society of Cinematographers' technology committee. DaVinci Resolve supports the 1.2 CDL standard that defines the slope, offset, and power for each of the red, green, and blue channels, as well as the overall saturation of each clip in a program.

CDL files are formatted similarly to EDLs, with SOP (Slope/Offset/Power), and SAT (Saturation) values embedded as metadata in much the same way as comments are in a more typical EDL.

Here's an example of a single CDL event:

```
020  001  V  C  03:02:49:13  03:02:53:00  01:01:28:11  01:01:31:22

*ASC_SOP  (1.109563  1.717648  0.866061)(-0.238880  -0.390357  0.353743)
 (0.672948  1.384022  0.889876)

*ASC_SAT  1.000000
```

Because the CDL definition of a grade is so narrow, projects you're planning to export to other applications via a CDL must be constrained to only those operations the CDL mathematically defines. Here are some things to keep in mind:

- Only primary corrections in the first node of each clip are exported.
- Restrict yourself to using the Lift/Gamma/Gain, Offset, and Saturation controls.
- Keyframes are never exported. If keyframes are present in a grade, only the parameter values at the first frame of the clip are used.
- The track grade and group grades are completely ignored.
- If there is an HSL Qualifier or a Power Window in the first node, it is ignored and the corrections in that node are exported as if it were a primary correction.
- Do not make Y' only adjustments; they're not compatible with CDLs. To ensure that your exported CDL is accurate, set the Lum Mix parameter in the Primary Controls palette for each grade to 0. For workflows involving frequent CDL export, you can turn on the "Luminance Mixer defaults to zero" option in the Color section of the General Options panel of the Project Settings to guarantee this parameter is always set to 0.

If your timeline conforms to all of these restrictions, then you're ready to export a CDL.

To export a CDL:

1. Open the Edit page, right-click the Timeline you want to export in the Media Pool, and choose Timelines > Export > CDL from the contextual menu.
2. Enter a name for the CDL, choose a location to save it to, and click OK.

> For more information on importing a CDL to add grades to your project, *see Chapter 147, "Copying and Importing Grades Using ColorTrace."*

Exporting the Edit Index as a CSV or TXT File

You can export the current contents of the Edit Index, in the Edit page, as a self-contained file to use for reference in a variety of ways.

To export the Edit Index:

1. Open the Edit Index, and choose one of the Edit Index filters from the Edit Index option menu, if necessary. For example, you could filter the edit index by Offline Clips Only if you wanted to export a list of all offline clips in the current timeline.
2. Right-click that timeline in the Media Pool, and choose Timelines > Export > Edit Index, then choose a location and export format from the Export Edit Index dialog, and click Save.

Exporting to ALE

DaVinci Resolve is also capable of exporting ALE (Avid Log Exchange) files. ALE is a tab-delimited, ASCII text-based clip logging list format that enables the exchange of clip metadata that can't be embedded inside MXF files. ALE files are designed to let you export a log of all clips that are used in a particular timeline with all of the metadata that's associated with those clips in DaVinci Resolve, so this metadata can be imported into and associated with clips inside Media Composer or Symphony.

ALE files are divided into three sections, labeled Heading, Column, and Data:

- The Heading provides information about the clips being logged, including the picture and audio format, and the frame rate.
- The Column line defines each of the columns of metadata being exported in the list. There's an automatic minimum of metadata columns that are automatically included, regardless of whether they're populated or not. However, additional metadata columns are automatically added to this list by DaVinci Resolve when any corresponding metadata field in the Metadata Editor is populated. For example, if you enter information into the Camera, Keyword, and Shot fields of the Metadata Editor, then those columns will be added to the exported ALE. There are no user settings that control this.
- The Data section contains multiple lines, one for each event being referenced in the list, that contain all the data corresponding to that clip.

If you're exporting stereoscopic clips from stereoscopic timelines, the following additional columns of metadata are automatically included in the two ALE files that are generated:

- Pan (relative to timeline resolution)
- Tilt (relative to timeline resolution)
- Zoom
- Rotate
- Convergence (relative to timeline resolution)
- HFlip (0 or 1)
- VFlip (0 or 1)

If you're exporting ALE files from projects using ARRIRAW clips, the following additional columns of metadata can be included:

- Temperature
- Tint

To export an ALE file:

1. Open the Edit page, right-click the Timeline you want to export in the Media Pool, and choose Timelines > Export > ALE from the contextual menu.
2. Enter a name for the ALE file, choose a location to save it to, and click OK.

   The ALE file is saved, and a dialog appears reminding you of the file path to which it was saved (click OK to dismiss it).

Here's an example of a short ALE export:

```

```

NOTE: The commas shown above are not normally in the ALE but shown here for field clarity.

Exporting to ALE with CDL

Avid Media Composer and Symphony also support the import of ALE files with additional CDL metadata columns with which to associate SOP (Slope/Offset/Power) and SAT (Saturation) adjustment metadata to each clip that's logged in the ALE.

When you import an ALE with CDL file into Media Composer, the SOP and SAT data populate metadata columns for preservation and export in various Avid workflows. Here's an example of the Heading, Column, and Data sections of a sample ALE with CDL, with one line of clip and CDL data.

To export an ALE with CDL file:

1. Open the Edit page, right-click the Timeline you want to export in the Media Pool, and choose Timelines > Export > ALE and CDL from the contextual menu.
2. Enter a name for the ALE file, choose a location to save it to, and click OK.

   The ALE file is saved, and a dialog appears reminding you of the file path to which it was saved (click OK to dismiss it).

Here's an example of a short ALE with CDL export:

```
Heading

```

NOTE: The commas shown above are not normally in the ALE but shown here for field clarity.

Exporting Timeline Markers to EDL

This command lets you export a quick report listing the text of all markers that have been added to the Timeline as notes in an EDL. Clip markers are ignored. This report is in EDL format, with one event for each Timeline marker, with a placeholder reel number (001 by default), and source and record timecodes that correspond to each marker's position in the Timeline (with a duration of one frame). An EDL note for each event lists the Marker note, if there is one. There is no note available for the color of the markers

Here's an example of an exported Timeline Marker EDL:

```
TITLE: ( no title )

001   001    V    C    01:00:09:09 01:00:09:10 01:00:09:09 01:00:09:10

Replace with another car door sound effect

002   001    V    C    01:00:20:12 01:00:20:13 01:00:20:12 01:00:20:13

Trim this clip shorter

003   001    V    C    01:00:30:12 01:00:30:13 01:00:30:12 01:00:30:13

Find another stock footage clip of the bridge

004   001    V    C    01:00:30:13 01:00:30:14 01:00:30:13 01:00:30:14

Trim this montage three seconds shorter
```

Exporting and Importing Media Pool Metadata

DaVinci Resolve makes it possible to export metadata from the Media Pool of one project for import into the clips of another project, for instances where you need to move metadata around. This process exports all metadata from the Media Pool as a .csv file.

For example, a DIT might have entered a lot of metadata to the DaVinci Resolve project used for generating dailies, but then an impatient editor might have created a separate project to begin editing those dailies. Instead of requiring the editor to enter each clip's metadata all over again, you can export the metadata from the DIT's project and import it into the editor's new project, automatically matching the relevant metadata to each corresponding clip.

To export Media Pool metadata:

1. Open a project containing Media Pool metadata you want to export.
2. Optionally, select which clips in the Media Pool you want to export metadata for.
3. Choose File > Export Metadata From > Media Pool to export metadata from every clip in the Media Pool, or choose File > Export Metadata From > Selected Clips to only export metadata from clips you selected in step 2.
4. When the Export Metadata dialog appears, enter a name and choose a location for the file to be written, then click Save. All metadata is exported into a .csv file that can be viewed and/or edited in any spreadsheet application.

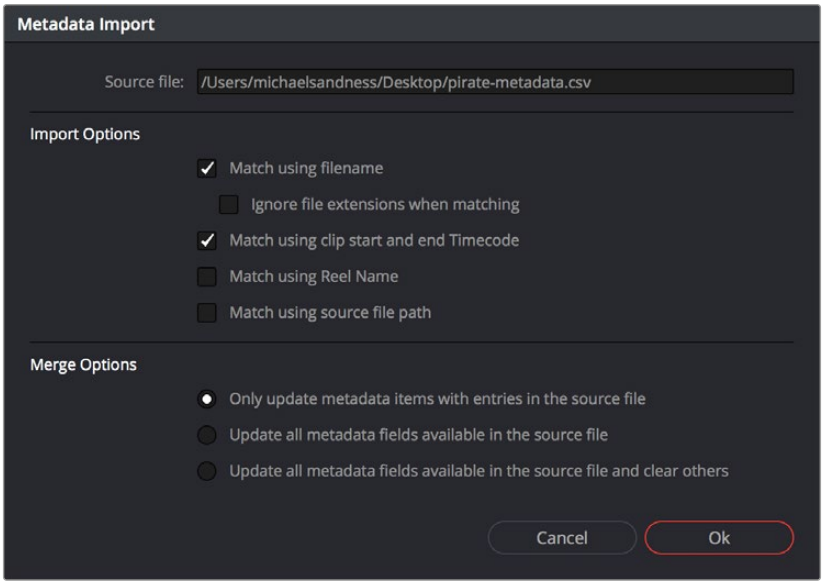
To import Media Pool metadata:

1. Open a project containing clips you want to populate with imported metadata.
2. Optionally, select which clips in the Media Pool you want to import metadata to.
3. Choose File > Import Metadata To > Media Pool to import metadata to potentially every clip in the Media Pool, or choose File > Import Metadata To > Selected Clips to only import metadata to clips you selected in step 2.
4. When the Import Metadata dialog appears, choose a metadata .csv file to import, and click Open.
5. When the Metadata Import dialog appears, choose the Import Options you want to use to match the .csv file's metadata to the correct clips in the currently open project. By default, DaVinci Resolve tries to use "Match using filename" and "Match using clip start and end Timecode" to match each line of metadata in the .csv file with a clip in the Media Pool, but there are other options you can use such as ignoring file extensions, using Reel Name, and using source file paths.
6. Next, choose which Merge Option you want to use in the Metadata Import dialog. There are three options:

   Only update metadata items with entries in the source file: The default setting. Only updates a clip's metadata if there's a valid entry in the imported .csv file. Other clip metadata fields are left as they were before the import.

   Update all metadata fields available in the source file: For each clip that corresponds to a line of metadata in the imported .csv file, every single metadata field referenced by the .csv file is overwritten, regardless of whether or not there's a valid entry for that field.

   Update all metadata fields available in the source file and clear others: For each clip that corresponds to a line of metadata in the imported .csv file, every single metadata field referenced by the .csv file is overwritten, regardless of whether or not there's a valid entry for that field. Furthermore, metadata fields that aren't referenced by the imported .csv file are cleared of whatever metadata was there before.



The Metadata Import dialog that lets you choose options for how to match and merge imported metadata

7. The Metadata Import dialog that lets you choose options for how to match and merge imported metadata
8. When you're finished choosing options, click Ok and all available metadata from the source .csv file will be imported.

Setting up a Cloud-Based Collaboration Workflow 3927

Cloud Project Libraries

Cloud project libraries are hosted on Blackmagic's Project Library servers on the internet, allowing DaVinci Resolve users to connect and collaborate on the same projects from any location in the world.

Connecting to a Blackmagic Cloud Project Library

Blackmagic houses project library cloud servers in various locations around the world that users can access for a nominal monthly fee. While Blackmagic does host the project files, no actual media is stored on the Blackmagic servers making it still a very secure method of working remotely.

To sign into to the Blackmagic cloud:

1. Sign up for a Blackmagic ID using your email address and credit card at http://blackmagicdesign.com
2. In the Project Manager Window select Cloud from the Project Library icons in the upper left.
3. Chose the Blackmagic Cloud option from the Sign-In dialog, and input your Blackmagic ID and Password.
4. If you are a member of an Organization Profile, you can choose to sign into that account or your personal account.

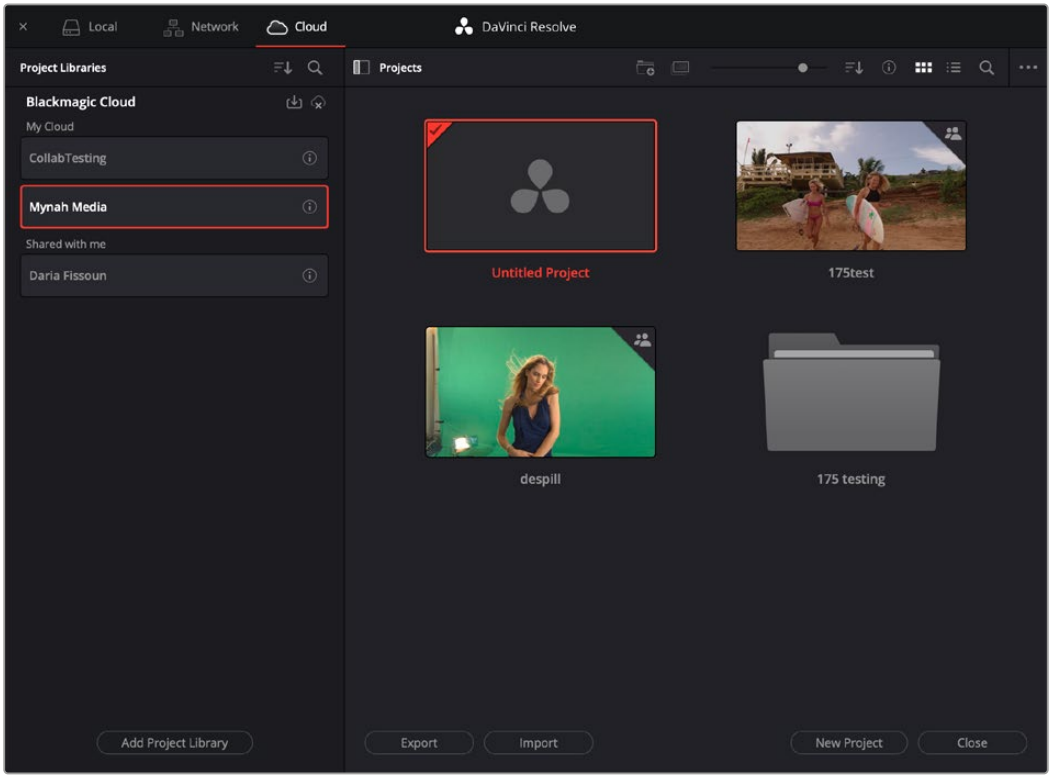
The Blackmagic Cloud login dialog box

To sign out of the Blackmagic cloud:

1. In the Project Manager window, select Cloud from the Project Library icons in the upper left.
2. Click on the Sign Out icon (The small cloud with an "x" under it) in the upper right of the Blackmagic Cloud panel.

Accessing the Cloud Project Library in DaVinci Resolve

Once connected, cloud project libraries are accessed by clicking on the Show/Hide Project Libraries icon in the upper left of the Project Manager. A sidebar then opens up showing all your connected project libraries. Click on the Cloud icon to open up the cloud project library. It is split into two sections: "My Cloud," which manages all the project libraries that you create, and "Shared with me," which shows project libraries that other users have created, but given you shared access to.



The Blackmagic cloud library

Optimization and Performance of a Cloud Project Library

Before learning about how to create and manage cloud project libraries, it's worthwhile addressing server lag and optimizations. The project library is a database of all the edits, clip metadata, visual effects, color corrections, and audio engineering applied to your timeline. This project library is queried and updated constantly as you use DaVinci Resolve. When the project library is local to, or on the same network as your workstation, these updates happen more or less instantaneously. However, when the project server is half-way around the world on the internet, the speed of light and internet routing start to insert perceptible lag time.

Luckily the majority of the changes required to mitigate this have been done by the DaVinci Resolve team. They have re-written the underlying project library code over a period of several months to optimize it for internet performance, and in most cases the responsiveness will be indistinguishable from using a local project library. However, these types of processes involve intensive and persistent project library operations, and some lag will become apparent when:

- Changing cloud project libraries
- Loading a project from the cloud project library
- Backing up and restoring cloud project libraries

It's important to keep in mind, that once loaded, actually working in DaVinci Resolve will still be as fluid and responsive as you are used to working with local libraries.

TIP: The major optimization that the user can make in cloud library performance is to decide where to physically locate the server. The best performance will be found closest to the city where the team is working. In some cases, the team will be working in multiple cities and countries around the world. In those cases, the server should be hosted in the region of the person who uses the project library the most, and that person is the editor. In the Edit and Cut pages, the project library is written to whenever the user releases the mouse button, while on the Color page the project library is only written to when you select a new clip. So for the best performance, you want to host the server location as close to the editor as possible.

Creating a New Cloud Project Library

Creating a new cloud library requires manually adding it on the Blackmagic Cloud website.

To create a new cloud project library:

1. Tap on the Cloud icon to Sign into the Blackmagic cloud server in the Project Manager.
2. Tap on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.
4. Tap on the “Add Project Library” button at the bottom of the sidebar.
5. A web browser will open up, automatically taking you to the Blackmagic Cloud web interface.
6. Tap on the “Add Project Library” button at the bottom of the sidebar in your web browser
7. Enter a new name for your cloud project library, and then select the region in the world in which you want to host the server. It is best to select a server closest to the project’s editor, and then the Version of Davinci Resolve you want the library to be compatible with.
8. Press the Add button.

   You can now create or import new projects directly into your new cloud project library.

Deleting or Renaming a Cloud Project Library

If you are finished with a particular cloud project library and want to delete it or wish to change its name you can do so through the Project Libraries interface.

To delete a cloud project library:

1. Sign into the Blackmagic cloud server in the Project Manager.
2. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.
4. Right-click on the library you want to delete in the Project Libraries sidebar, and select Delete from the drop-down menu.
5. Click the Delete button on the confirmation dialog box that opens.

   Deleting a cloud project library is a permanent and not undoable action. Make sure you have everything you need from this library before you click delete. Once it’s gone, it’s gone.

To rename a cloud project library:

1. Sign into the Blackmagic cloud server in the Project Manager.
2. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.

4 Right-click on the library you want to rename in the Project Libraries sidebar, and enter the new name in the dialog box.

5 Click the OK button.

TIP: You can not delete or change the name of the currently connected project library (indicated by an orange highlight around it). In order to do so, you must select and connect to another project library first, and then apply the steps above.

Upgrading a Cloud Project Library

From time to time, new versions of DaVinci Resolve require changes to the way projects are created, which requires project libraries created with older versions of DaVinci Resolve to be upgraded before you can access the projects within. Fortunately, this is a simple process.

To upgrade a cloud project library:

1 Sign into the Blackmagic cloud server in the Project Manager.

2 Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.

3 Select the Cloud icon from the Project Library options.

4 Right-click on the library you want to upgrade in the Project Libraries sidebar, and select Upgrade from the drop-down menu.

5 Click the upgrade button on the confirmation dialog box that opens.

Sharing a Cloud Project Library

You can share a cloud project library with other users around the world with a Blackmagic ID.

To share a cloud project library:

1 Sign into the Blackmagic cloud server in the Project Manager.

2 Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.

3 Select the Cloud icon from the Project Library options.

4 Click on the Details icon (the circled letter “i”) on the cloud project library you wish to share to open the details settings.

5 A members list will appear, and your user name and email will be first on the list with a little crown icon, showing that you are the owner of this project library.

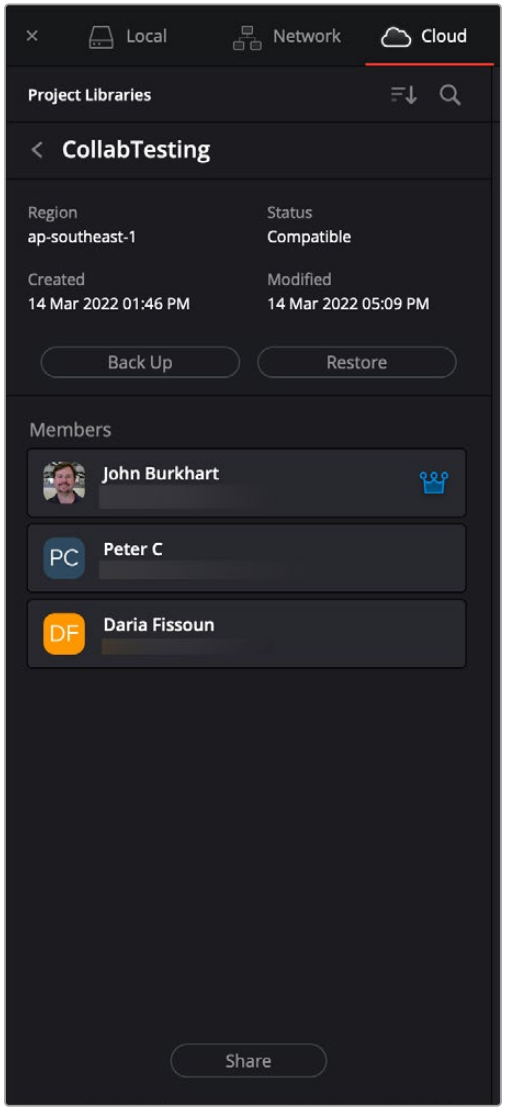
6 Click the Share button at the bottom of the sidebar.

7 Enter the Blackmagic ID (email address) of the person you want to share this project library with.

8 Press the Share button.

The user will instantly have access to this shared library, and an email will inform them as well. If the user was already logged in with their Blackmagic ID, they will have to log out and re-login again for the shared project library to show up in their cloud library.

IMPORTANT: The users you share your project library with have access to modifying and deleting any projects within that shared library, so be judicious about who you give access to.



The Members section of the Blackmagic cloud library

Removing a User from a Shared Cloud Project Library

If you are the owner of a shared cloud project library, you can remove another shared user's access to it.

Removing a shared user from a cloud project library:

1. Sign into the Blackmagic cloud server in the Project Manager.
2. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.
4. Click on the Details icon (the circled letter "i") on the cloud project library you wish to share to open the details settings.
5. A members list will appear, showing all users that have access to this project library.
6. Right-click on the user you wish to remove and select Remove Member from the drop-down list.

Backing up and Restoring a Cloud Project Library

You can back up and restore a cloud project library in the Blackmagic cloud itself.

To back up a cloud project library:

1. Sign into the Blackmagic cloud server in the Project Manager.
2. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.
4. Click on the Details icon (the circled letter “i”) on the cloud project library you wish to back up to open the details settings.
5. Click the Back Up button.
6. After some time, a dialog box will appear confirming the backup has been made to the cloud.

To restore an older version of a cloud project library:

1. Sign into the Blackmagic cloud server in the Project Manager.
2. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
3. Select the Cloud icon from the Project Library options.
4. Click on the Details icon (the circled letter “i”) on the cloud project library you wish to restore to an earlier version to open the details settings.
5. Click the Restore button.
6. Navigate to the version that you want to restore in the Backups list.
7. Assign a new name to the restored library.
8. Click the Restore button.

Blackmagic Cloud Support for Importing ATEM Projects

If you’re working with ATEM switchers, and use the workflow of creating multiple ISO feeds and the accompanying DaVinci Resolve project, you can now log into a Blackmagic Cloud project library, select an existing DaVinci Resolve cloud project, and use the Camera Uploads mechanism to synchronize recorded media to DaVinci Resolve. DaVinci Resolve collaborators can see the edit decisions made from the switcher as a new timeline in that project.

- The DaVinci Resolve project needs to be set to synchronize camera originals to see the uploaded media from the switcher.
- New timelines may use custom settings if the ATEM resolution or frame rate differs from project settings.

Setting up a Cloud-Based Collaboration Workflow

As internet bandwidth has increased over the years, it has recently become possible to collaborate on a project completely online. While once you needed to be in the same building connected to a fast LAN, and Network Attached Storage (NAS), it is now possible to collaborate in real time from all around the world using the internet and cloud storage instead. Below are instructions for setting up a completely cloud-based workflow using the tools and settings in DaVinci Resolve 18 or higher.

This sample workflow consists of Editor A, Colorist B, and Audio Engineer C, all in different parts of the world, and wanting to collaborate on the same project at the same time. The ideal is to minimize the amount of media management involved and to not have to send individual project files back and forth.

Set up the Blackmagic Cloud and a Cloud Library

- Users A, B, and C sign up for the Blackmagic cloud service.
- Users A, B, and C log into the cloud in the Project Manger in their own copies of DaVinci Resolve.
- User A creates a new cloud library, and invites Users B and C to share it. Since User A is the editor, they will locate the cloud library's server nearest themselves.

Set up the Cloud Storage

- Users A, B, and C sign up for a cloud storage provider (Dropbox, iCloud, OneDrive, Google Drive, etc.)
- Users A, B, and C configure their cloud storage so they all can share access to the same cloud-based folder. This folder should be at the top level of the cloud storage. They decide to name the folder Episode 12.
- Users A, B, and C create a file hierarchy system in their shared Episode 12 folder, such as new subfolders for Audio, Proxies, and Graphics.
- Users A, B, and C mount their shared storage folder on their own computers. Editor A adds some logos and still photos to the Graphics folder. Audio Engineer C adds some music and sound effects to the Audio folder. This takes a while to upload and distribute from the cloud, but eventually all users have the same media locally on their computers.

Create the Proxy Media

- Colorist B has the RAW camera masters on a hard drive connected to their system. Since only they need access to the RAW camera files for color grading, they will make low bandwidth proxies for the Editor and Audio Engineer to work with. These files are small enough to upload and store in their cloud storage folder.
- Colorist B creates proxy files of the RAW media in the Blackmagic Proxy Generator application.

> For more information on using the Blackmagic Proxy Generator, *see Chapter 8, "Improving Performance, Proxies, and the Render Cache."*

- Colorist B uploads the proxy files to the Proxies folder in their cloud storage.

Setup the DaVinci Resolve Project and Settings

- Colorist B creates the new project in the cloud library, and sets up its resolution and frame rate, etc.
- Colorist B turns on the File > Multiple User Collaboration setting.
- Users A, B, and C open the project and set their individual file paths to their cloud storage folder "Episode 12" in the Path Mapping section of the Project Settings.

> For more information on Path Mapping, *see Chapter 6, "Project Settings."*

- Colorist B imports the RAW media from their local hard drive into their Media Pool, and links them to the proxies he uploaded to the Episode12/Proxies folder. At this point, Editor A, and Audio Engineer C now have access to the proxy media, while Colorist B can switch back and forth between RAW media and Proxies as needed. If necessary, Colorist B can also decide to upload the RAW media to the shared folder if space and time allow. While the other users are waiting for this media to upload, if they have the “Prefer Camera Originals” setting checked in Playback > Proxy Handling menu, they can continue to edit using the proxies, and as the RAW media files upload, they will automatically replace the proxy files as they come in.
- Editor A imports their still photos to the Media Pool from the Episode 12/Graphics folder. They immediately become available to Users B and C without relinking.
- Audio Engineer C imports their music tracks to the Media Pool from the Episode 12/Audio folder. They immediately become available to Users A and B without relinking.
- As the users continue to add more media into the shared folder and bring it into the Media Pool, there may be a lag as the media is uploaded to the cloud storage, and then downloaded to the other users. During this time the clip will appear as media offline but will relink automatically once the file finishes its download to the local computer.

Continue working in DaVinci Resolve’s Collaborative Workflow

From here, the editor edits, the colorist colors, and the audio engineer handles the sound design all using DaVinci Resolve’s existing collaborative workflow tools.

For more information on using these tools, *see Chapter 193, “Collaborative Workflow.”*

Chapter 189

Blackmagic Cloud Storage

This chapter describes how to set up and use your Blackmagic Cloud Storage.

Contents

Blackmagic Cloud Storage 3931

Setting up a Blackmagic Cloud Project 3931

Blackmagic Cloud Sync Manager 3933

Automatic Proxy Generation and Upload to Blackmagic Cloud Storage 3935

Cloud Storage Sync Icons 3935

Blackmagic Cloud Storage

Blackmagic Cloud Storage provides a centralized and secure space online for your media assets and proxies. How you use this space is up to you, from a multi-user world-wide collaboration session, to a single user just picking up their laptop and leaving their workstation behind, to simply having a secure back up of media from an old spinning hard drive. Blackmagic Cloud Storage is completely integrated into DaVinci Resolve and the existing Blackmagic Cloud service.

All Blackmagic Cloud users, both new and existing, get a limited amount of free storage.

You can log into cloud.blackmagicdesign.com to access this storage, and purchase project libraries and/or additional storage. User plans and prices are listed there.

The Free Storage can be used to:

- Upload camera captures from the Blackmagic Camera app.
- Downloads require logging into the Blackmagic Cloud Website, and manually downloading the clips.

The Paid Storage can be used to:

- Sync media and proxies for DaVinci Resolve Cloud collaboration projects.
- Remote Camera Collaboration from the Blackmagic Camera app.
- Upload camera captures from the Blackmagic Camera app.

Setting up a Blackmagic Cloud Project

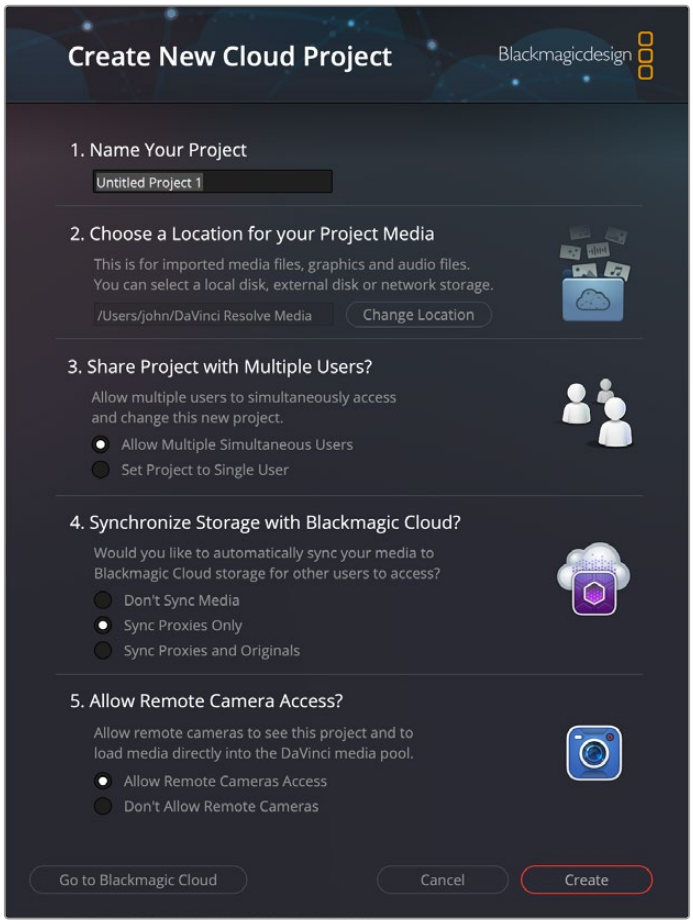
Setting up a Blackmagic Cloud based project has been refined and simplified in 18.6, allowing you to set up all the configuration options, including Blackmagic Cloud Storage, from one easy setup screen.

NOTE: To use Blackmagic Cloud, you must first sign up for a Blackmagic Cloud account at cloud.blackmagicdesign.com and then sign into your account in DaVinci Resolve.

To setup a new Cloud Project:

1. From DaVinci Resolve's Project Manager, select Cloud from the Project Library options in the upper left. Your Blackmagic Cloud Library should be active (highlighted in orange).
2. Click the New Project button or right-click in the background and select New Project from the contextual menu. Or import an existing local DaVinci Resolve project that you want to add to the Blackmagic Cloud.
3. Choose the options you want in the Create New Cloud Project dialog.
4. Click the Create Button.

The Create New Cloud Project dialog box lets you set up the media locations and sharing parameters of your project.



Select Remove Unused Clips from the Media Pool option menu

- **Name Your Project:** Type in a name for your Cloud Project.
- **Choose a Location for your Project Media:** Choose a location on your file system for imported media files, graphics, and audio files you wish to use for the project.
- **Share Project with Multiple Users?:** Lets you determine if you want to share this project with other users.

  Allow Multiple Simultaneous Users: Enables collaboration mode for working with multiple people on the same project concurrently.

  Set Project to Single User: Disables collaboration mode and is designed for one person working on the project at a time.
- **Synchronize Storage with Blackmagic Cloud?:** These options let you choose what media to upload and sync to your Blackmagic Cloud Storage account for other users' access.

  Don't Sync Media: Does not upload any media to Blackmagic Cloud Storage.

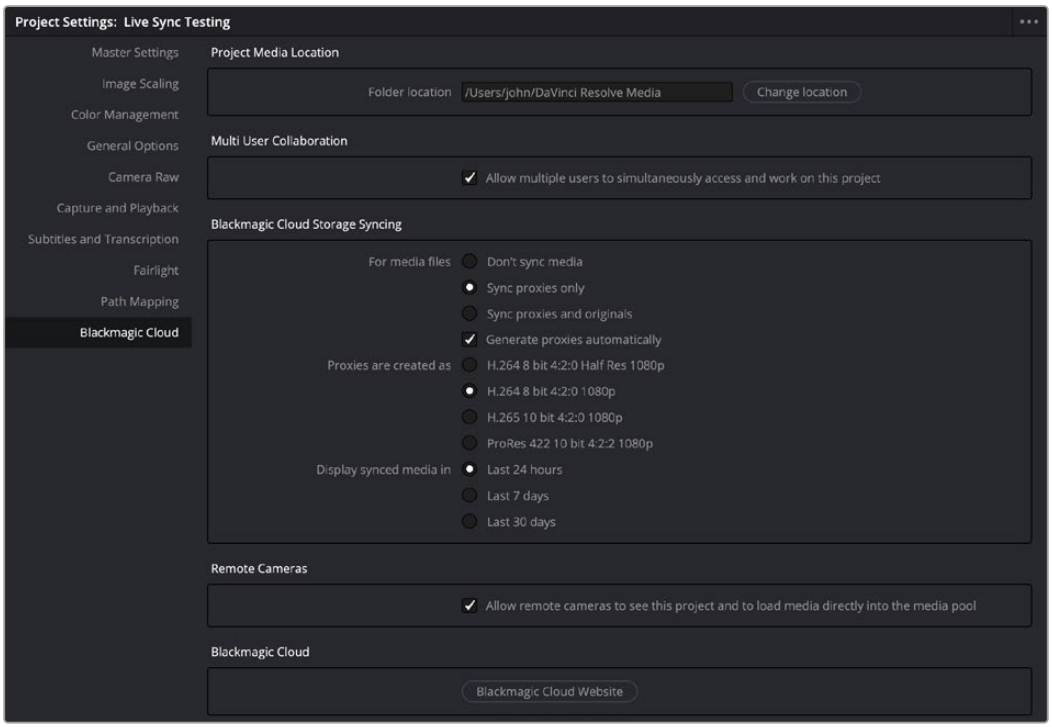
  Sync Proxies Only: Uploads only proxy media to Blackmagic Cloud Storage.

  Sync Proxies and Originals: Uploads both proxies and the original media to Blackmagic Cloud Storage. This can use an extremely large amount of storage depending on the amount and size of the original media.

- **Allow Remote Camera Access:** Sets permissions for users of the Blackmagic Camera app.
- **Allow Remote Cameras Access:** Allows Blackmagic Camera app users that are members of this project to upload media from their phones to the Blackmagic Storage account and will add it to the project's Media Pool directly.
- **Don't Allow Remote Cameras:** Does not allow Blackmagic Camera app users to upload footage to this project, even if they happen to be a member of it.

One you press Create, a new project will be made with the parameters you've set above.

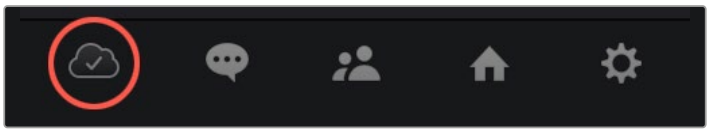
If at any time you wish to change these parameters after a project has been created, you can access them again by opening the Project settings, and selecting the Blackmagic Cloud tab.

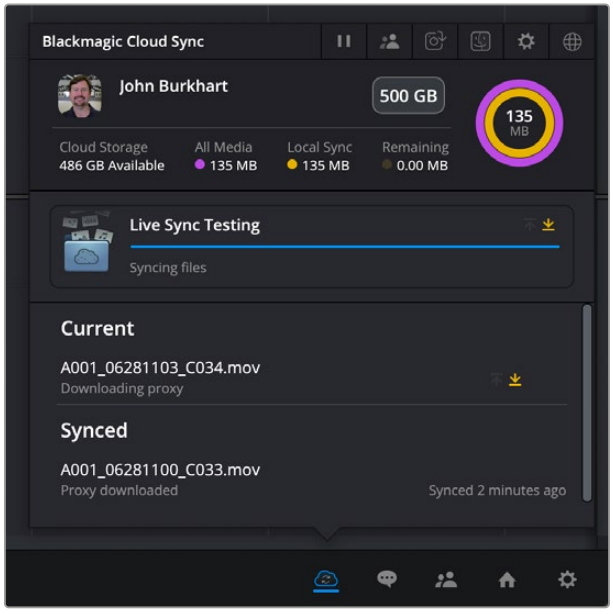


You can modify all the cloud settings of an existing Blackmagic Cloud project in the Project Settings.

Blackmagic Cloud Sync Manager

When working with a project in a cloud library, several of the most common cloud management functions can be accessed directly by clicking on the Blackmagic Cloud Sync Manager in the lower right of the interface. This icon only shows up when working with a cloud library.





The Blackmagic Cloud Sync Manager opens an array of useful cloud management tools.

From Left to Right on the top bar, the following tools are available:

	Pause/Resume Sync: Pauses or Resumes the upload and download of media from the host computer.
	Enable/Disable Multi User Collaboration: Opens a dialog box to toggle between Set to Single User or Allow Multiple Users (collaboration mode).
	Enable/Disable Camera Capture: Opens a dialog box to toggle between Allow or Don't Allow Blackmagic Camera app users to upload footage to storage and import the clips to the project's Media Pool.
	Open in Finder/File Explorer: Opens the Project Media Location in the computer's file system.
	Open Settings: Opens the Blackmagic Cloud tab in the Project Settings window.
	Go to Blackmagic Cloud Storage: Opens up your web browser to the Blackmagic Cloud Storage page on the internet.

Underneath this toolbar there are two status areas. The top one shows the user logged into the Blackmagic Cloud account and how much Blackmagic Cloud Storage has been used and is available. The ring display shows the total of all media in the outside ring, the amount of media synced locally in the middle ring, and how much media is left to upload in the inside ring.

The bottom one shows the progress of the media syncing over the internet. The top display shows the progress bar on the sync status and how much material is left to sync. Directly underneath that is the media list showing the current clip syncing, and a list of media that has already synced.

Automatic Proxy Generation and Upload to Blackmagic Cloud Storage

When in the Media, Cut, Edit and Fairlight pages, DaVinci Resolve can automatically generate proxies in the background to upload to Blackmagic Cloud. In all pages, users can still explicitly generate proxy media from the media pool to start uploads.

To enable automatic proxy generation and upload:

1. In the Project Settings, click on the Blackmagic Cloud tab.
2. In the “For media files” section, click on “Sync proxies only.”
3. Check the “Generate proxies automatically” box.
4. In the “Proxies are created as” section, select the codec you want the proxy format to be rendered to.
5. Click on the Save button.

To disable automatic proxy generation and upload:

1. In the Project Settings, click on the Blackmagic Cloud tab.
2. In the “For media files” section, click on “Don’t sync media.”
3. Uncheck the “Generate proxies automatically” box.
4. Click on the Save button.

Cloud Storage Sync Icons

If you are working in a cloud library, there are Sync icons in the upper left of a clip in the Media Pool that let you know the status of each clip’s status in the cloud.

 The Proxy Processing icon in the upper left	**White Cloud with 3 Dots:** This icon indicates that proxy media is currently being processed.
 The Upload Queue icon in the upper left	**Yellow Cloud with an Up Arrow:** This icon indicates that the clip is in the queue for being uploaded to the cloud.
 The Successful Sync icon in the upper left	**White Cloud with a Checkmark:** This icon indicates that the clip has successfully been uploaded and synced to the cloud.

Chapter 190

Blackmagic Cloud Presentations

This chapter describes how to use the Presentations application in the Blackmagic Cloud, allowing you to setup review and collaboration sessions online with people from around the world.

Contents

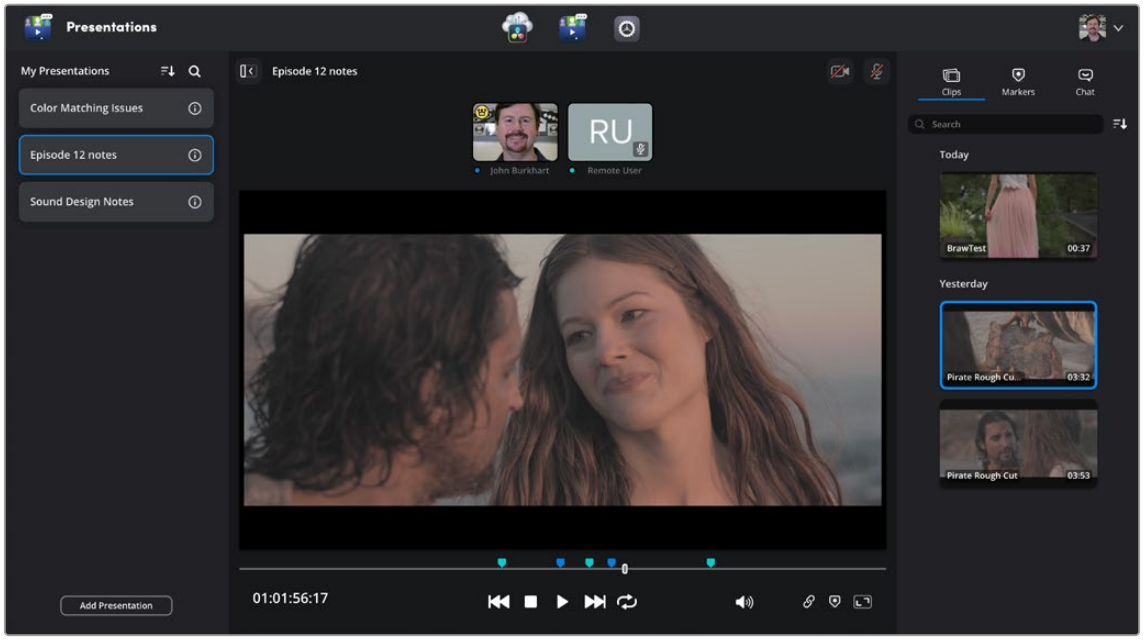
Presentations in DaVinci Resolve 3946
Sending a Timeline to Presentations 3946
Using Markers Between Presentations and DaVinci Resolve 3947

Blackmagic Presentations

The Presentations application in Blackmagic Cloud allows real time collaboration and review of DaVinci Resolve timelines using only an internet browser. Collaboration tools consist of video conferencing for real time communication, a chat interface for persistent notes and comments, and markers that sync directly with a DaVinci Resolve timeline. With these tools, you can play back a video with frame accurate sync for all users, while video conferencing at the same time.



The Blackmagic Presentations application in a web browser

The Presentations application is comprised of three parts. The left column is My Presentations, where all your different presentations are created, stored, and organized. The center area is the Viewer that lets you navigate the clip, add markers, and adjust the audio playback. On top of the Viewer is the Video Conferencing area, allowing you to collaborate in real time with other members. The right column is divided into three sections: Clips, Markers, and Chat. Clips show all the available clips to comment and collaborate on. Markers will show a list of markers and comments that sync with a DaVinci Resolve timeline. Chat opens up a simple chat interface to have a record of your notes and comments.

NOTE: As of this writing, Presentations is still in beta. As beta software, the features described below may be changed, redesigned, or removed completely from the final release.

Creating and Managing Presentations

Online collaboration in Presentations is comprised of two parts: first, the Presentation in the Blackmagic Cloud and secondly, a timeline from a DaVinci Resolve workstation (described below). This section describes the creation and management of Presentations.

NOTE: Presentations uses a slightly different nomenclature describing clips than DaVinci Resolve. In Presentations, a “clip” is a DaVinci Resolve “timeline,” and not a clip that you would find in the Media Pool.

Creating a New Presentation

Each presentation can be thought of like a project in DaVinci Resolve, except that it’s about discussion rather than post production. Presentations contain multiple “clips” to review and have a variety of collaboration tools, rather than editing/color/fx/audio tools. While making a new presentation for each project is perfectly valid, you can also make presentations based off other criteria, like who is collaborating, a date, or a specific stage of the post production process.

The My Presentations column

To Create a Blackmagic Cloud Presentation

1. Log into your Blackmagic Cloud account in a web browser at www.blackmagicdesign.com.
2. Select the Presentations icon in the upper center of the web page.
3. In the My Presentations column, click on the Add Presentation button in the lower left.
4. Select a Name for the presentation and click Add.
5. Click on the Presentation in the My Presentations column to launch it.

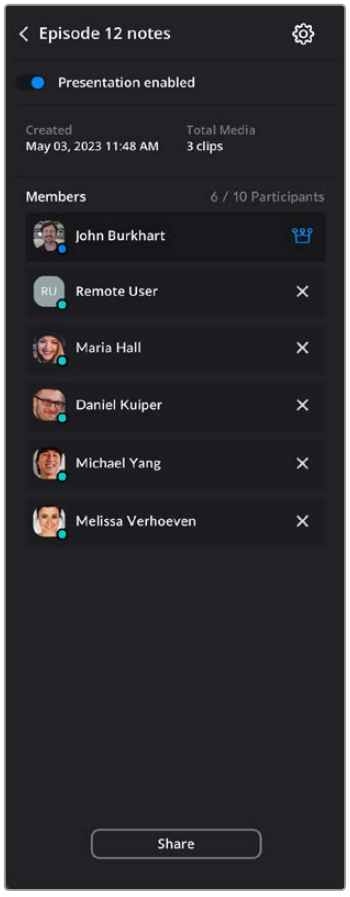
If you find you have more presentations than can fit on the screen, the My Presentations column can be sorted by name and date in ascending or descending order by clicking on the sort icon just to the right.

The My Presentations column is also searchable by clicking on the magnifying glass to the right and entering your search terms. Only presentations matching your search terms will be shown.

Until you upload your first clip from a DaVinci Resolve project, the Viewer will show “Upload clips from DaVinci Resolve to get started.” That process is described below in the “Sending a Timeline to Presentations” section.

Sharing a Presentation with Another User

You can share a presentation with up to 10 other users. The only requirement is that each user has their own Blackmagic Cloud account.



The information panel of a presentation

To Share a Blackmagic Cloud Presentation

1. Click on the information icon (the circled letter i) next to the presentation name. A Members pane is exposed, showing all the current users that the presentation is shared with. The user with the crown icon is the presentation administrator, and only they can add or remove users.
2. Click on the Share button at the bottom of the Members pane.
3. Enter the email address (used to create the Blackmagic Cloud account) of the user you wish to share the presentation with.
4. Click on the Share button.

   The user's name will now appear in the Members pane, and the presentation will show up in their own My Presentations column when logging into the Blackmagic Cloud. They can now watch any clips, video conference, or make comments in that presentation.

Additionally, an email will be sent to the user's email address, notifying them of the presentation and a direct link to access it.

To remove a user from a presentation, simply click on the "x" next to their name in the Members panel. Only the administrator can add or remove members.

Enabling and Disabling a Presentation

The administrator can choose to temporarily disable a presentation. This is used to temporarily lock access to the presentation without deleting it. This keeps all the clips, users, and comments in place and only prevents the presentation being viewed or modified until it's enabled again.

To Enable or Disable a Blackmagic Cloud Presentation

1. Click on the Information icon (the circled letter i) next to the presentation name.
2. Click on the Presentation enabled switch directly below the presentation name to toggle between enabling and disabling the presentation.

Renaming a Presentation

The administrator can easily rename a presentation to more accurately describe its purpose or contents.

To Rename a Blackmagic Cloud Presentation

1. Click on the Information icon (the circled letter i) next to the presentation name.
2. Click on the Settings icon (the small gear) next to the presentation name.
3. Select Rename from the drop-down menu.
4. Type in the new name for the presentation.
5. Click on the Save button.

The presentation's name will be then updated in the My Presentations column for all users.

Deleting a Presentation

When you've finished with a presentation, the administrator can delete it from the Blackmagic Cloud. A deleted presentation permanently removes all clips and comments and is not undoable, so make sure you are completely finished before you delete it.

To Delete a Blackmagic Cloud Presentation

1. Click on the Information icon (the circled letter i) next to the presentation name.
2. Click on the Settings icon (the small gear) next to the presentation name.
3. Select Delete from the drop-down menu.
4. Click on the Delete button in the warning dialog box.

Leaving a Presentation

As a user you can leave a Presentation at any time. This removes permission for you to view and edit the presentation, and removes it from your My Presentations column. If you wish to gain access to a presentation again once you've left, the presentation administrator must re-share it with you.

To Leave a Blackmagic Cloud Presentation

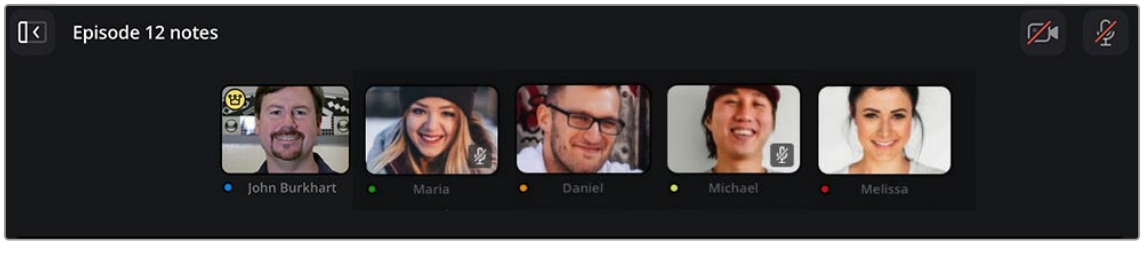
1. Click on the Information icon (the circled letter i) next to the presentation name.
2. Click on the Settings icon (the small gear) next to the presentation name.
3. Select Leave from the drop-down menu.
4. Click on the Leave button in the warning dialog box.

Using Presentations

The heart of Presentations is the Viewer; here you can both video conference and control the playback of a clip. The Viewer provides a low latency, streaming video that you can use to accurately mark and comment on, as those comments show up in real time to other users and on the DaVinci Resolve timeline.

Video Conferencing

The top strip of the Viewer contains a basic video conferencing interface, with each user's video stream appearing in a live thumbnail. By default the camera and microphone are turned off, so you will need to switch them on manually.



The video conferencing interface; note the Camera and Microphone on/off controls in the upper right.

To Turn On and Off the Camera and Microphone for a Blackmagic Cloud Presentation

1. Click on the Camera and/or Microphone icons in the upper right of the Viewer.
2. Give your OS and browser appropriate permissions to use the devices.
3. To turn off the Camera and Microphone, click their respective icons again.

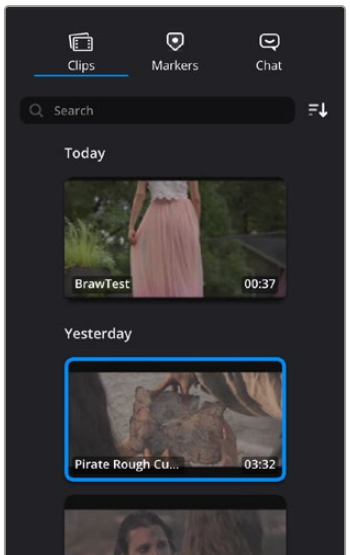
With your camera and microphone on, all other connected users will see and hear you through their web browsers, so be generous and discrete with your comments.

Controlling a Clip in the Viewer

Each user can view and comment on any of the clips (including the same clip) in real time. The Viewer for each user is independent of all the others, though the administrator has the option to sync everyone's Viewer to their own, in order to watch the same clip at the same time.

Selecting a Clip

Selecting a clip to view is as easy as clicking on the clip's thumbnail in the Clips column. Clips are sortable by date, duration, and name in ascending or descending order. The Clips column is also searchable by clicking on the magnifying glass to the right and entering your search terms. Only clips matching your search terms will be shown. You can also hover your pointer over the clip thumbnail to scrub through the video.



The Clips column

Administrators can edit the names, and delete clips from the presentation by hovering over the thumbnail and selecting the appropriate icons (pencil and trashcan) in the upper right.

Viewer Controls

The Presentations Viewer has a set of playback controls at the bottom of the browser that you can use to position your playhead exactly.

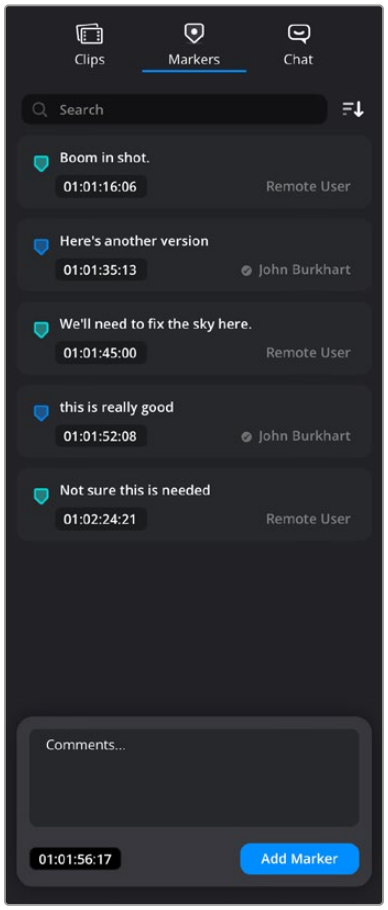
The Viewer controls

	**Jog Bar:** The long line across the bottom of the browser shows your current playhead position as a rectangle and any markers that have been set. You can click and drag the playhead to scrub back and forth in the clip.
	Timecode: The timecode of the current clip that refers back to the original DaVinci Resolve timeline.
	Previous Clip: (Up Arrow) Loads the clip above the current clip in the Clips column into the Viewer. If the current clip is already at the top of the stack, it will wrap around to the clip at the bottom.
	Stop: Stops playback of the clip in the Viewer.
	Play: Plays the clip in the Viewer forward at 1x speed.
	Next Clip: (Down Arrow) Loads the clip below the current clip in the Clips column into the Viewer. If the current clip is already at the bottom of the stack, it will wrap around to the clip at the top.
	Loop: Toggles between no looping (the default), Loop One which will loop the current clip over and over, and Loop All which will play back all the clips in the Clips column and loop back to the beginning of the stack.
	Volume: Clicking on this icon mutes the audio. Dragging the slider next to the icon controls the volume of the clip.
	Start Sync: (Administrator only), clicking this icon allows the contents of your Viewer to display for all members. The administrator's view overrides the Viewers of all the other users, ensuring that everyone is watching the same thing at the same time.
	**Add Marker:** Clicking this icon adds a marker at the playhead position. Editing and commenting on this marker is done in the Markers column described below.
	Full Screen: This expands the Viewer to take up the entire screen.

NOTE: You can move the playhead frame by frame forward and back by using the left and right arrow keys respectively.

Using Markers

There are three ways to make your opinion known on a clip in Presentations. The first is speaking directly through video conferencing as described above, the second and third are through markers and chat.



The Markers column

Markers allow you to make written comments attached to a specific frame of video. This lets you give targeted advice exactly where it needs to be. The main benefit of using markers is that they also immediately transfer to the DaVinci Resolve timeline used to make the clip. This ensures that your comments make it back to the editor/colorist/audio engineer as they work on the project.

To Add a Marker to a Clip at the Playhead Position, do one of the following:

- Click on the Add Marker icon in the Viewer.
- Tap the letter M on your keyboard.
- In the Markers column, write your comment in the text box at the bottom, and click on the Add Marker button.

Markers will show up as a triangle that is the same color as the colored dot associated with the user's thumbnail in the Video Conferencing pane.

To Edit the Text Contents of a Marker:

1. Hover over the marker in the Markers column, and tap on the Pencil icon.
2. Write your comment in the text box.
3. Click on save.

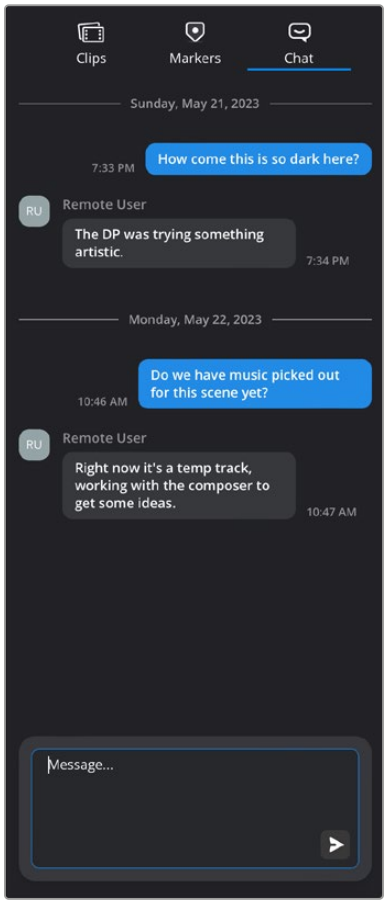
To Delete a Marker from a Clip:

1 Hover over the marker in the Markers column, and tap on the Trashcan icon.

2 Click on Delete in the warning dialog.

Using Chat

The Chat column gives you a simple text-based conversation tool that is persistently saved. This lets you leave notes, comments, and refer back to previous sessions if necessary. The Chat column is not tied to any specific clip but to the presentation as a whole.



The Chat column

To Leave a Chat Comment:

1 Write your message in the text box at the bottom of the Chat column.

2 Press the Send icon.

Your message will appear in the chat window in chronological order. Chat messages you've sent will be unattributed and right justified. Messages other members sent will be left justified and have their names and User icon attached to them.

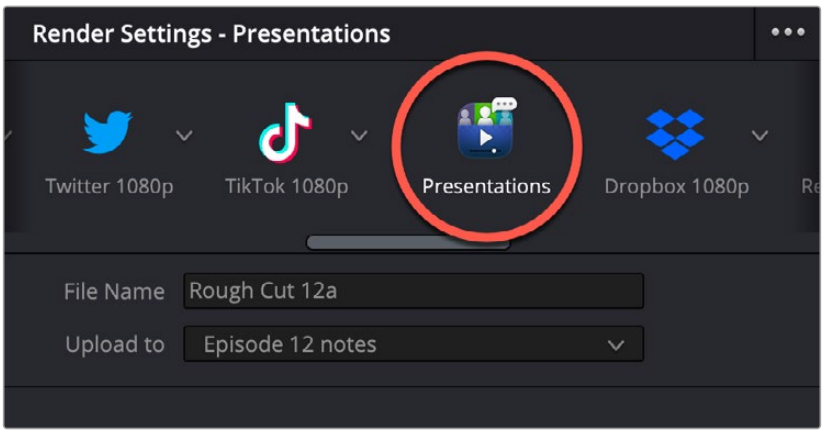
Currently, the chat is visible to all members of the presentation, and there is no way to delete a chat message once it is sent, so be kind.

Presentations in DaVinci Resolve

The Presentations application is designed to work in conjunction with DaVinci Resolve. Each “clip” in Presentations is linked to a DaVinci Resolve timeline. Any markers added by members in Presentations are updated to the timeline in DaVinci Resolve automatically and vice versa.

Sending a Timeline to Presentations

Each “clip” in Presentations is a DaVinci Resolve timeline. In order to populate the Clips column with footage to work with, you will first need to export your timeline from DaVinci Resolve to Presentations.



The Presentations Render Preset in the Deliver page.

To Send a DaVinci Resolve Timeline to Presentations:

1. Make sure you are signed into your Blackmagic Cloud account in the Internet Accounts section of the DaVinci Resolve Preferences.
2. Make sure you are a member of the presentation you wish to send the timeline to.
3. Open the timeline you wish to send.
4. In the Deliver page, select the Presentations render preset.
5. In the File Name field, type in a name for your timeline to appear as in Presentations.
6. In the Upload to field, select the presentation you wish to upload the timeline to. If the presentation is not in the list, see steps 1 and 2.
7. Click on the Add to Render Queue button at the bottom of the Render Settings.
8. Click on the Render All button under the Render Queue.

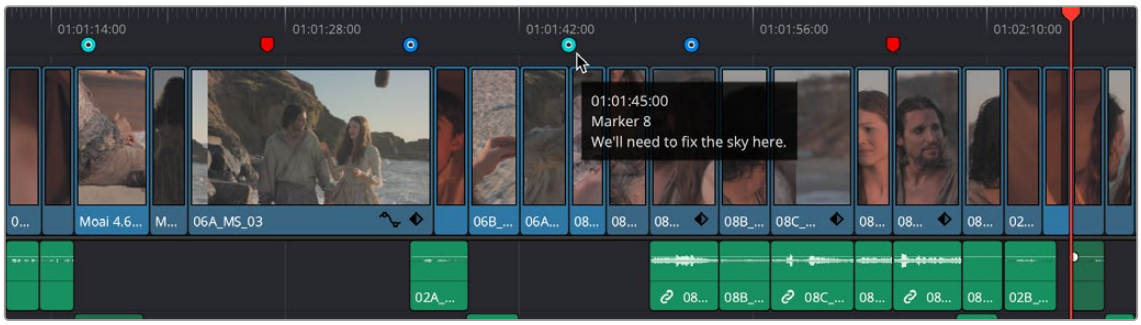
There are no video or audio codec parameters to set, and DaVinci Resolve will proceed to render your timeline and upload it automatically to the selected presentation. Any member can upload a timeline to a presentation, not just the administrator.

The timeline will now appear as a “clip” in the Clips column of the presentation.

Using Markers Between Presentations and DaVinci Resolve

A key benefit of Presentations is persistent markers between a presentation and a DaVinci Resolve timeline. Once a timeline has been uploaded to a presentation, it's automatically linked behind the scenes and any markers added, either in the Presentations app or in DaVinci Resolve, will sync with each other.

On the DaVinci Resolve side, the sync occurs when a timeline is open, and the user is logged in to the Blackmagic Cloud. For example, markers can be added by members the previous night and will then sync when the editor opens the timeline in the morning. You can also collaborate live with a presentation if the members are online and the editor is working in the timeline, updating markers in real time.



Presentations markers are circular in shape and are synced between the timeline and its associated Presentations clip.

Markers that are linked to Presentations display as circular on the DaVinci Resolve timeline to differentiate them from normal markers that are triangular in shape. Presentations Markers will also reflect the color of the member creating the marker.

Markers don't just travel one way from Presentations to DaVinci Resolve. While working on a timeline in DaVinci Resolve, the user can add special Presentations markers that will sync and show up in the Presentations application, to be viewed by all members.

To Add a Presentations marker on a DaVinci Resolve Timeline:

1. You must have already uploaded a timeline to Presentations as described above.
2. Place the playhead in the Timeline where you want the Presentations marker.
3. Select Mark > Add Marker > Presentations.

To Delete a Presentations marker on a DaVinci Resolve Timeline:

1. Select the circular Presentations marker on the Timeline.
2. Press the Delete key.
3. Click on the Delete button in the warning dialog.

Deleting a Presentations marker will remove it from both the Timeline and the presentation itself. This operation is not undoable. The timeline user is able to delete a Presentations marker from any member, not just their own.

Chapter 191

Live Sync

This chapter describes how to edit using the Live Sync feature with DaVinici Resolve, Blackmagic Cloud and Blackmagic Cameras.

Contents

Live Sync 3949

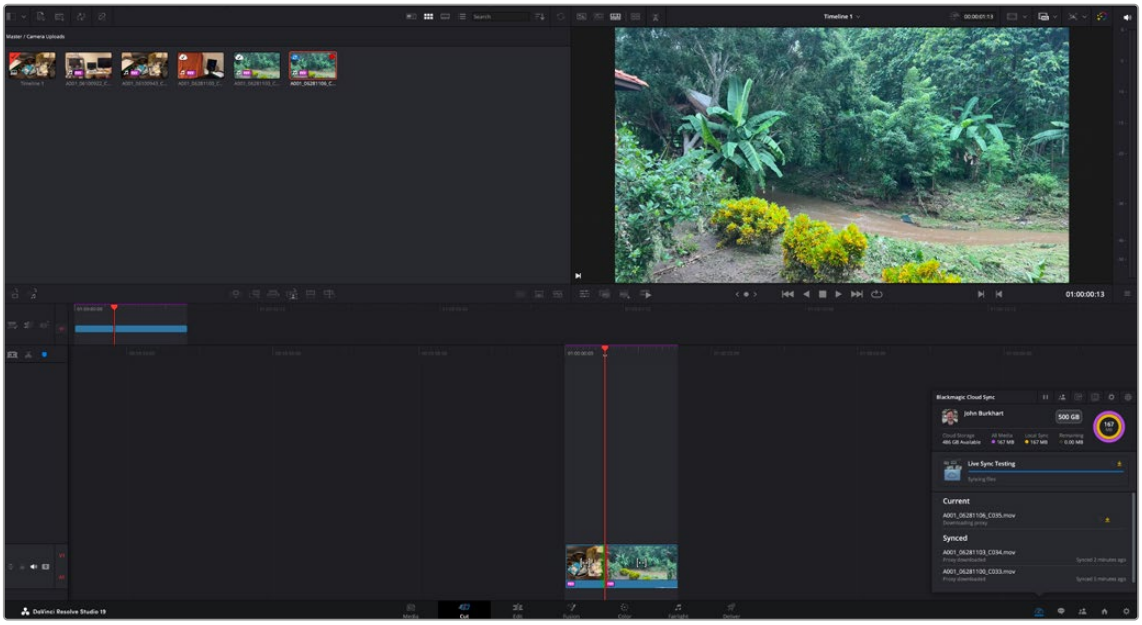
Editing Live Sync in DaVinci Resolve 3953

Live Sync

Live Sync allows the near real time editing of camera files as they are being recorded. This has obvious benefits for time sensitive applications, such as news and live events, however even scripted drama and documentaries can benefit from editing as you go for quick turnarounds.

Live Sync automatically will start uploading an HD H.265 proxy file, even while the master clip is still being recorded in the camera. This file is immediately accessible from the Media Pool in DaVinci Resolve. As the clip continues to be recorded in the camera, the clip continues to grow in the Media Pool, letting you access future events from the same clip. As each clip finishes, the Media Pool grows with new proxy clips. Depending on your need, you can export your final project using this proxy media for immediate delivery or relink your footage to the camera masters later for the highest-quality output.

Live Sync is an integrated system requiring a Blackmagic Camera, Blackmagic Cloud Storage, and DaVinci Resolve to work seamlessly. This chapter will explain how to set up these three elements to work together.

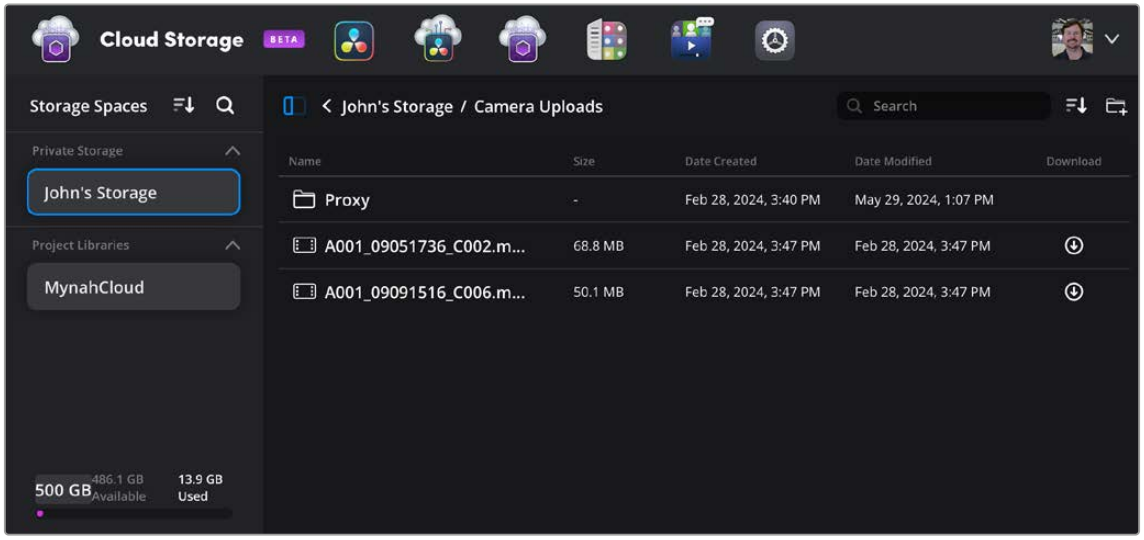


Editing a live clip as it is being recorded in the Cut page. The Blackmagic Cloud Sync Manager is in the lower right.

Setting Up Live Sync on Blackmagic Cloud Storage

In order to record and edit Live Sync footage, you first need somewhere accessible to both the editor and the camera operator to store the project and camera files, and that place is Blackmagic Cloud Storage. At the minimum you will need enough cloud storage space to hold all of the proxy files from the Blackmagic Camera. If you also wish to upload the camera originals, you will need considerably more space, depending on the codec the camera is using.

For more information on setting up a Blackmagic Cloud Storage account and purchasing space, *see Chapter 189, "Blackmagic Cloud Storage."*



The Blackmagic Cloud Storage web interface

Once you have your Blackmagic Cloud Storage space and project library set up, after the first clip is recorded from a Blackmagic Camera, you will see a Camera Uploads folder created. Inside that folder is a Proxy subfolder (where all the Live Sync proxies will be stored), and a list of currently uploaded master clips. Having this specific folder helps organize and separate your incoming camera footage from any other media folders you have in your storage.

NOTE: While you can do simple media management (deleting and organizing clips) in the Blackmagic Cloud Storage web interface, the media management tools both in the Blackmagic Camera and DaVinci Resolve are much better suited for this purpose. It's best to leave the Cloud Storage simply as a passive sync from these devices.

Setting up Live Sync on Blackmagic Cameras

Each Blackmagic Camera model will have its own method of uploading clips to the Blackmagic Cloud; please see your camera's documentation on the specifics for that model. Below are the instructions for setting up the Blackmagic Camera app for iOS and Android.

Setting up Live Sync with the Blackmagic Camera App for iOS and Android

When you sign into Blackmagic Cloud on your Blackmagic Camera app, you can choose to upload clips directly to a DaVinci Resolve Cloud project or to manually select the clips you want to upload from your camera's media pool. Alternatively, clips can also be uploaded straight to your own private Blackmagic Cloud storage directly, without syncing to a Resolve Cloud project.

You can choose to upload proxy files or both proxy and original files in Settings > Media > Upload Clips.

Logging into Blackmagic Cloud

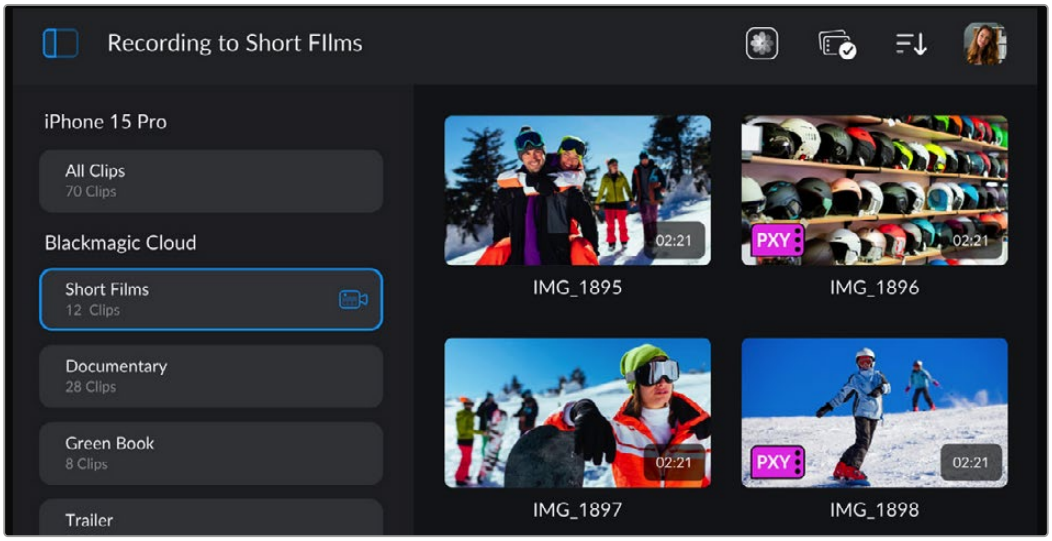
To log into your Blackmagic Cloud account:

1. Go to Settings > Blackmagic Cloud > Log in to Blackmagic Cloud, or tap the Blackmagic Cloud icon in the upper right of the Media workspace.
2. Enter your login details, tap 'login' and use the touchscreen keyboard to enter your email address and password.

   Once logged in, your Blackmagic Cloud avatar will be displayed in the Media and Chat workspaces. You can tap your avatar to view your account details or to log out of your account.

Blackmagic Cloud Projects Panel

Tap the sidebar icon at the top left of the Media workspace to open the Blackmagic Cloud projects panel.



When you are signed into your Blackmagic Cloud account, projects that you can upload clips to are listed in the 'Blackmagic Cloud' section of the Viewer.

Uploading Clips to a Blackmagic Cloud Project

Selecting a Blackmagic Cloud project lets you upload proxy files, or both proxies and originals, as you record clips to your camera's media. When a project is selected in the projects panel, a clip will be immediately uploaded as soon as you stop recording on your phone. This will happen in the background as you continue recording clips for as long as your phone is connected to the Internet and logged into your Blackmagic Cloud account.

To upload to a Blackmagic Cloud project:

1. Tap on a Blackmagic Cloud project to select it.
2. Tap the the Camera icon to close the Media Pool and return to the HUD.
3. The name of the selected Blackmagic Cloud project will appear above the timecode display on your phone's HUD. The next time you record a clip, your camera will automatically start uploading media to the selected cloud project.

   If your phone's internet connection is interrupted, the name of the cloud project will be grayed out and uploads paused. Your camera will automatically restart the uploading process when the internet connection is restored.

When you have finished recording, tap on the Media icon to open the Media Pool and view the upload status of your clips.

Your Blackmagic Cloud avatar will remain visible in the menus and you will stay logged in, even if you have disconnected your phone from the internet. This ensures that any recordings you have in your project upload queue will resume as soon as possible after connecting your phone again. Your phone will immediately try to reestablish your internet connection and resume any uploads it has in its queue.

This also means when you choose to record directly into a project, you can operate in areas with patchy cellular coverage and not worry about reconnecting to upload as the process happens automatically. For example, you could record clips in locations where there is no Internet connection or cellular signal at all, and then simply connect when you are in range or have a wifi Internet connection and quickly upload your proxies then.

Live Sync

Turn this slider on in the Media Settings to immediately start uploading a proxy file to your Blackmagic Cloud project as you record a clip. The clip will appear in your DaVinci Resolve Cloud project, and grows dynamically in the Media Pool as the recording comes in over the internet. This lets the editor work on the first part of a shot even while it's still being recorded in real time. The editor can always return to the same clip again and again for additional material as it grows.

The speed at which the Live Sync clip updates is dependent on the speed of your internet connection.

Clip Upload Status Indicators

When you have chosen to upload clips to a Blackmagic Cloud project, you can check the upload status by selecting the project from the Blackmagic Cloud projects panel.

Next to the cloud project name, the overall upload status is displayed including number of clips, completed percentage, upload speed and estimated time remaining.

Live Sync in DaVinci Resolve

Setting up a Cloud Project in DaVinci Resolve

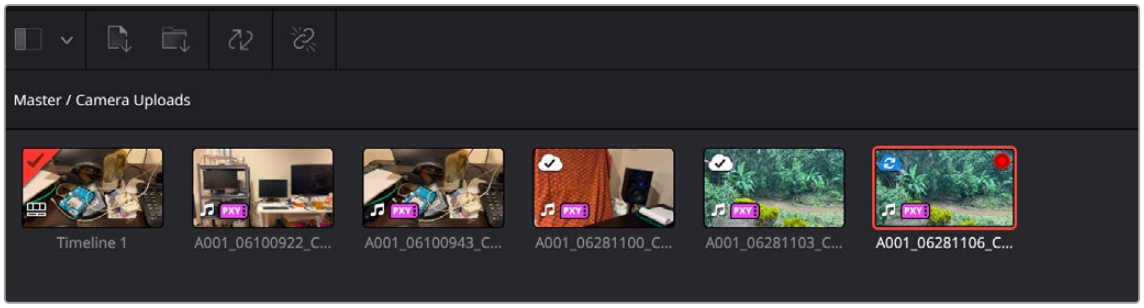
Before starting a Live Sync editing session, you will have to create a Cloud project in DaVinci Resolve that the camera can link to. This can be a new or existing Cloud project. For Live Sync to function, the “Allow Remote Camera Access” button in the Create New Cloud Project dialog box must be turned on.

> For more information on setting up a Cloud Project, *see Chapter 189, “Blackmagic Cloud Storage.”*

Editing Live Sync in DaVinci Resolve

Once you’ve opened your Cloud project in DaVinci Resolve, you can start editing live footage as it comes in. You can edit from either the Cut or Edit pages.

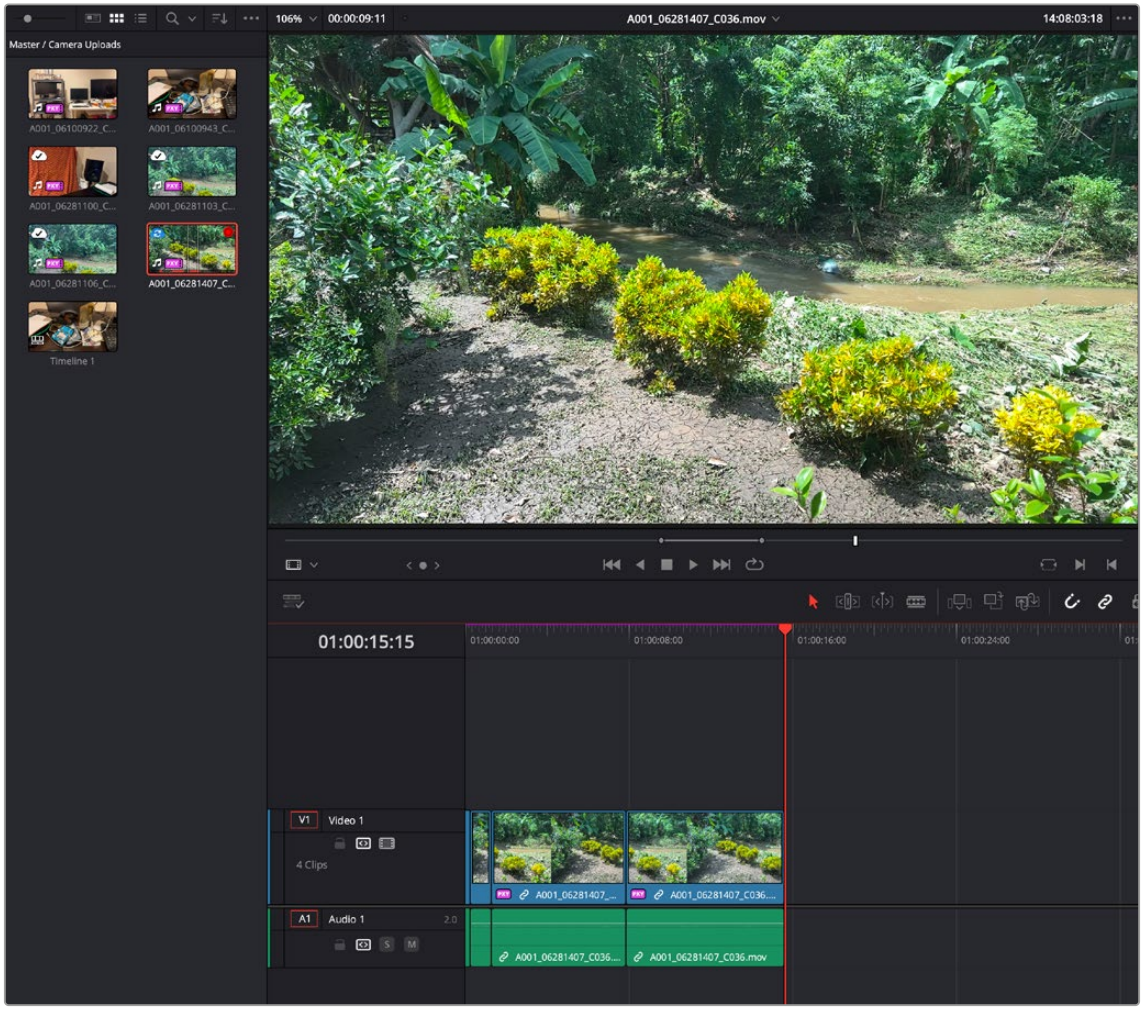
In the Media Pool, a folder called Camera Uploads is created. This folder is where all the Live Sync media will be accessed from. Each thumbnail in the folder has icons that tell you the status of each clip. A red dot in the upper-right corner of a clip shows you which clip is currently “live” and being recorded to at the moment.



The Cut page Media Pool showing the proxy and sync status of the clips in the Camera Uploads Folder. The clip with the red dot in the upper-right corner is currently being recorded “live.”

Working with Live Sync Clips

Working with Live Sync clips in the Cut or Edit pages is very similar to working with normal clips with the exception that the Live Sync clip is constantly expanding. What this means in practice is while you are scrubbing the footage and marking In and Out points in the Viewer, the Live Sync clip automatically gets longer as new material is downloaded. This process does not require any action on the part of the editor to “refresh” the clip, so there is never any need to leave the Viewer. As the clip grows and something newly interesting happens, you can update the clip with a new set of In and Out points to edit it into the timeline. You can always leave the Live Sync clip to edit with other previously recorded shots, and it will still be there when you return... quietly growing....



The Edit page showing a Live Sync clip growing in the Source Viewer. As the clip grows in size, you can update the In and Out points in the Viewer to add new sections of the clip into the timeline.

The Live Sync clip is limited in length only by your storage capacity, and the speed at which it updates is dependent on the speed of the internet connection for both the Blackmagic Camera and the DaVinci Resolve workstation.

Project Libraries, Collaborative, and Remote Workflows

Chapter 192

Managing Project Libraries and Project Servers

This chapter describes how to set up and use project libraries in greater detail, giving you more control over how projects are saved and organized.

The chapter details how to set up local, network, and cloud project libraries you can use to administer DaVinci Resolve projects that are available to multiple DaVinci Resolve workstations.

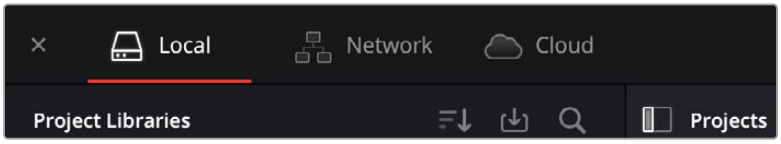
What is a Project Library?

A Project Library (formerly project database), is a database file storing one or more DaVinci Resolve projects. When you create or load a project from the Project Manager, or save a current project, you read from or write to a project library. A project library contains multiple projects, and each project contains all the timelines, grades, clip metadata, visual effects, audio mixing, etc. for your film. A project library does not store the original media itself, only the instructions on how to use that media to create a finished film. DaVinci Resolve can access multiple project libraries, but can only connect to one project library at a time.

Using Project Libraries

Setting up a structure for storing projects and project libraries is an important part of creating streamlined and efficient workflows. For example, creating a separate project library for each TV series, commercial, or film a post house is working on helps compartmentalize your clients, and improves performance by only loading up what you need for a specific project.

There are three ways DaVinci Resolve uses to access project libraries, and the choice of which to use is largely determined by the amount of people working on the same project, and where they are in the world. Each option is described in detail below.



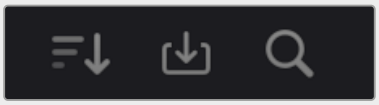
The three types of Project Libraries: local, network, and cloud

- **Local Project Libraries:** (the default option) Best used for productions using a single workstation to complete the entire film. Multiple people may work on the same project, but they work one at a time on the same machine. Your project libraries are stored locally on the computer where DaVinci Resolve is installed, and all media drives in the project are connected locally.

- **Network Project Libraries:** Best used for post houses or productions that have multiple DaVinci Resolve workstations in the same building, and want to be able to work on the same project from each room, or collaboratively at the same time. Your project libraries are stored on a separate computer, running the DaVinci Resolve Project Server application. All workstations must be connected to this computer on the same local area network (LAN), and either connected to the same media drives via a NAS or MAM system, or each having a locally connected copy (or proxies) of the media available.
- **Cloud Project Libraries:** Best used for post houses, companies or productions that have multiple DaVinci Resolve workstations in different places around the world, and want to be able to work on the same project from each location individually, or collaboratively at the same time. Your project libraries are stored in the Blackmagic cloud service. All workstations must be connected to the internet, and each system must have a locally connected copy (or proxies) of the media available.

Navigating and using the Project Libraries sidebar is common to all the above types of project libraries.

Project Library: Each accessible project library is listed by name, and clicking on it will connect that library and its contained projects to DaVinci Resolve. You can choose from many libraries, but only one library can be active at a time.



Project Libraries sidebar controls
(L-R): Sort, Restore, Search

- **Sort Libraries:** Selects the sort order of how the project libraries appear, options are Name, Schema (date), Status, and Location. They can be sorted in both Ascending and Descending order.
- **Restore:** Allows you to load a project library that you previously backed up.
- **Search:** Allows you to search for a specific project library by text, and you can limit the search by Name, Schema, Status, and Location.

Local Project Libraries

Local project libraries are the simplest and most common type of project library and require no additional set up or configuration by the user, other than installing DaVinci Resolve. These libraries are saved locally to your workstation; by default they are placed in a folder called Resolve Disk Database, though they can be placed manually anywhere on your file system.

Creating a New Local Project Library

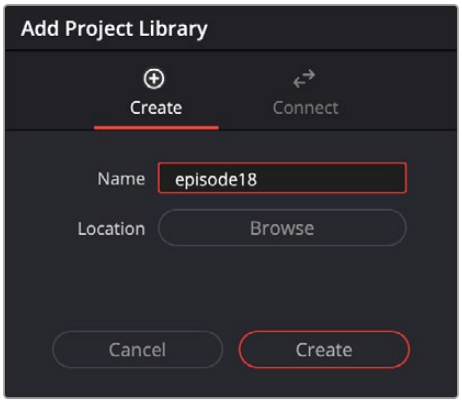
Creating a new local library is a simple and straightforward process.

To Create a New Local Project Library:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Local icon from the Project Library options.
3. Click on the “Add Project Library” button at the bottom of the sidebar.

4 Select the Create option to make a new project library.
5 Enter a new name for your project library.
6 Press the Browse button next to Location, to select where on your local computer to save the project library.
7 Press the Create button.

You can now create or import new projects directly into your new local project library.



Creating a local project library

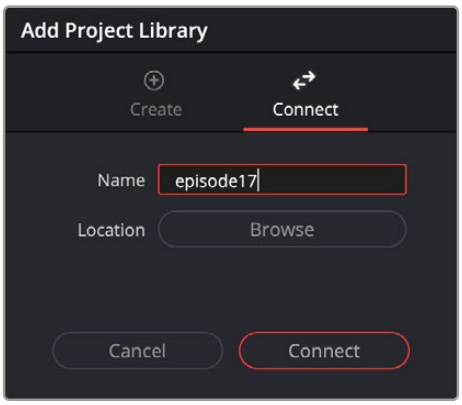
Connecting to an Existing Local Project Library

You can reconnect to an already existing project library using the following steps.

To connect to an existing project library:

1 Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager, to expose the sidebar.
2 Select the Local icon from the Project Library options.
3 Click on the “Add Project Library” button at the bottom of the sidebar.
4 Select the Connect option to access the existing project library.
5 Enter a new name for your project library.
6 Press the Browse button next to Location, to select where on your local computer the folder containing the existing project library is. It is commonly named “Resolve Disk Project library.”
7 Press the Connect button.

You can now view and use all the existing projects directly from the existing local project library.



Connecting to an existing local project library

Disconnecting from a Local Project Library

You can disconnect and remove an already existing project library from the Project Libraries list using the following steps.

To disconnect from a project library:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Local icon from the Project Library options.
3. Right-click on the project library that you want to disconnect from, and select disconnect from the context menu.
4. Press the disconnect button in the confirmation dialog.

Disconnecting a project library simply removes it from the available options in the Project Libraries sidebar. It does not delete the project library. You can either manually delete it in the OS filesystem, or reconnect to it using the steps described in Connecting to an Existing Local Project Library.

Duplicating Project Libraries

Local Project Libraries can be duplicated in the same database for backup or iteration purposes.

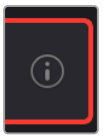
1. Right-click on the Library, and select Duplicate from the dropdown menu.
2. Select the Resolve Database Folder in the file system browser. This can either be the same one you use for the original project or a new one.
3. Click on the Open button.
4. Rename the new Library in the Clone Library dialog.

Backing up a Local Project Library

You can also back up project libraries by exporting them, and then reimport them later.

To backup/export a project library:

1. Select the project library you want to back up.
2. Click the Display Project Library Details icon (the circled letter “i” to the right of the project library).



The Display Project Library Details icon

3. Select the Back Up button.
4. Choose a location to which to save the backup in the Backup Project Library dialog, and click Save.

Restoring a Local Project Library

You can import existing project libraries to pass multiple projects between systems.

To restore/import a project library:

1 Click the Restore button at the top of the Project Libraries sidebar.

The Restore button

2 Find the project library you need to import using the file import dialog, and click Open.

3 In the Add Project Library dialog, do the following:

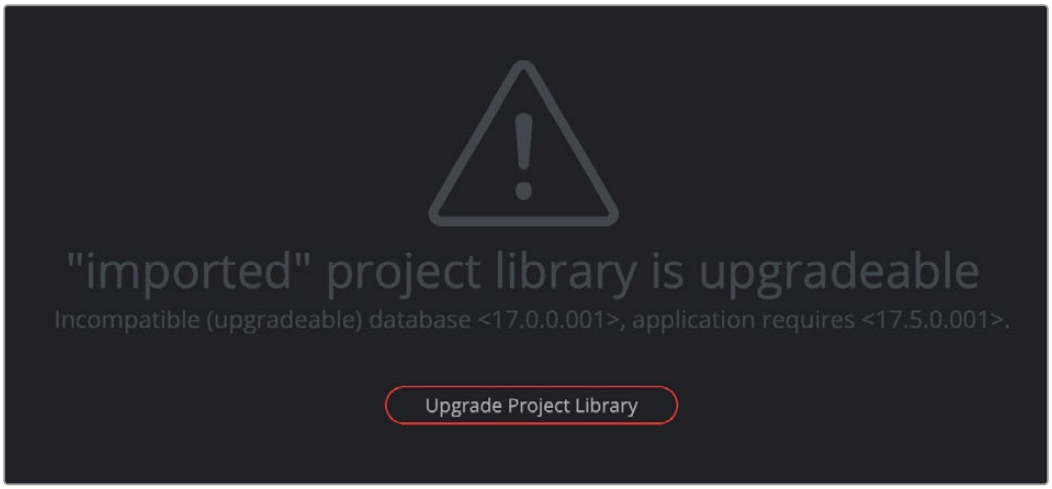
a) Type a name for the new project library into the Name field. This will rename the imported project library but will not alter its contents. You can also name it the same as the original project library.

b) Click within the Location field and use the Filesystem navigation dialog to choose the directory that contains the existing DaVinci Resolve project libraries.

4 Click Create, and the imported local project library will appear in the Local section of the Project Libraries sidebar.

Upgrading a Local Project Library

Selected libraries display an upgrade warning in the Project Manager only when you've installed a new version of DaVinci Resolve and you have project libraries that were created in older versions of DaVinci Resolve that need upgrading.



The upgrade warning in the Project Manager indicates that project library needs to be upgraded.

It's generally a good idea to back up a project library prior to upgrading it, in case something goes wrong. In general, upgrading from a whole version release to the next whole version release of DaVinci Resolve usually requires an upgrade, while upgrading to a dot release of the same version may or may not. If the currently used project library requires an update, you'll be told on application startup.

To upgrade a project library from an old version of DaVinci Resolve:

Click on a project library that needs updating, and select the Upgrade Project Library button. A dialog appears to confirm if you really want to upgrade that project library. Click Upgrade to proceed.

Network Project Libraries

Multiple DaVinci Resolve workstations can access the same project when you set up a Project Server that shares one or more network project libraries over a local network. Once you've set this up, there are two ways of using a shared project library.

Multiple Users Sharing Projects

The simplest case is for users to simply open up a project on the Project Server and work on it. Working this way, if you ever have to change rooms, or switch workstations, you can easily open that same project from any machine that's connected to the server on the same network without needing to export and import it first. For example, an assistant could be working with a colorist to prepare files for the next reel by conforming shots, managing VFX replacements, doing dust busting repairs, and so on in an unsupervised editing suite anywhere in the building, before saving their work and closing the project so the colorist can immediately open that same project in the grading theater across the hall.

Another way of taking advantage of shared Project Servers is to split large projects into sections, so multiple artists can work in parallel on different pieces of the whole in different suites, handing them off when necessary. For example, a feature film may be split into reels, or a film can be separated from the trailer and electronic press kit projects that it shares media with. In this case, each project can be edited, mixed, and graded by different people accessing the Project Server.

When a shared project is opened by someone else after it's already been opened, a dialog informs you that it's being opened in Read-only mode to prevent multiple users from accessing the project at the same time. If you load a Read-only project and decide you want to make changes anyway, you'll need to use the Save As command to create a duplicate project file using a new name in order to preserve your work.

Using Collaborative Workflow for Network Project Libraries

Alternately, you can use the Collaborative Workflow features in DaVinci Resolve to enable multiple collaborators on multiple workstations in multiple rooms to open and work on the very same project at the same time. For example, an editor can be editing a project's main timeline in one room, while an assistant organizes media and adds metadata within the same project in another room, and a colorist grades dailies in that same project in yet another room, all accessing the same Project Server which allows them to work together in parallel.

For more information, *see Chapter 193, "Collaborative Workflow."*

All participants in a Collaborative Workflow must be using a network project library on a Project Server that's properly set up.

Connecting to a Network Project Library on a DaVinci Resolve Project Server

The main difference between a local project library, and a network project library is that the network project library resides on another computer connected on the same network running the DaVinci Resolve Project Server. Setting up the Project Server itself is covered later in this chapter, but as a network project user in DaVinci Resolve you will need to understand how your local workstation connects to the Project Server.

Once the hardware and software install is done (essentially all computers connected on the same network, all running DaVinci Resolve, and one computer running the Project Server), you will need to authorize your computer to access the network project libraries on the Project Server and this is handled by "keys."

If you want to have access to a network project library you must be provided a key to it that is generated by the Project Server. The key is simply an .xml file with the extension ".resolvedbkey".

To use an access key to enable easy connection to a Project Server:

1. Open DaVinci Resolve, and when the Project Manager appears, open the Project Libraries sidebar.
2. Drag the .resolvedbkey file and drop it anywhere within the Project Manager.
3. The shared project library should now appear in the Project Libraries sidebar, and if you select it, you'll see all of the projects that are located in that project library on the Project Server.

   You also may have been set up as a Member of the Project Server, and provided your own username and password. If that is the case, see the section "Connecting to an Existing Network Project Library" below.

   Once you are connected to a network project library, you can manage them just as if you were connected locally.

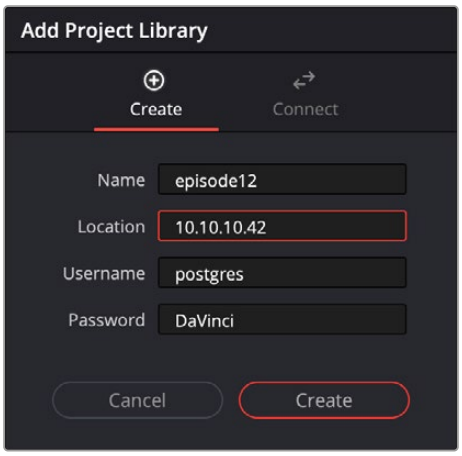
Creating a New Network Project Library

Creating a new network project library is a simple and straightforward process.

To create a new network project library:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Network icon from the Project Library options.
3. Click on the "Add Project Library" button at the bottom of the sidebar.
4. Select the Create option to make a new project library.
5. Enter a new name for your project library.
6. Enter the IP address of the DaVinci Resolve Project Server you're accessing.
7. If you are a Member of the Project Server, enter your Username and Password. Otherwise, use the default user: postgres and password: DaVinci.
8. Click on the Create button.

   You can now create or import new projects directly into your new network project library.



Creating a network project library

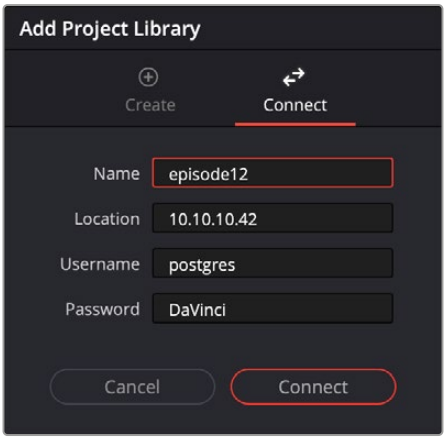
Connecting to an Existing Network Project Library

You can connect to an already existing project library on a Project Server by using the following steps.

To connect to an existing project library on a Project Server:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Network icon from the Project Library options.
3. Click on the “Add Project Library” button at the bottom of the sidebar.
4. Select the Connect option to access the existing project library.
5. Enter the name of the project library on the Project Server.
6. Enter the IP address of the DaVinci Resolve Project Server you’re accessing.
7. If you are a Member of the Project Server, enter your Username and Password. Otherwise, use the default user: postgres and password: DaVinci.
8. Press the Connect button.

   You can now view and use all the existing projects directly from the existing network project library.



Connecting to an existing network project library

Disconnecting from a Network Project Library

You can disconnect and remove an already existing project library from the Project Libraries list using the following steps.

To disconnect from a network project library:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Network icon from the Project Library options.
3. Select the project library you want to disconnect.
4. Click the Display Project Library Details icon (the circled letter “i” to the right of the project library).
5. Select the Remove button.
6. Press the disconnect button in the confirmation dialog.

   Disconnecting a project library simply removes it from the available options in the Project Libraries sidebar. It does not delete the project library. You can either manually delete it in the OS filesystem, or reconnect to it using the steps described in Connecting to an Existing Local Project Library.

Backing up a Network Project Library

You can also back up project libraries by exporting them, and then reimport them later.

To backup/export a network project library:

1. Select the project library you want to back up.
2. Click the Display Project Library Details icon (the circled letter “i” to the right of the project library).
3. Select the Back Up button.
4. Choose a location to which to save the backup in the Backup Project library dialog, and click Save.

Restoring a Network Project Library

You can import existing project libraries to pass multiple projects between systems.

To restore/import a network project library:

1. Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2. Select the Network icon from the Project Library options.
3. Click the Restore button at the top of the Project Libraries sidebar.

The Restore button

4. Find the project library you need to import using the file import dialog, and click Open.

5 In the Add Project Library dialog, do the following:

a) Enter a new name for your project library.

b) Enter the IP address of the DaVinci Resolve Project Server you're accessing.

c) If you are a Member of the Project Server, enter your Username and Password. Otherwise, use the default user: *postgres* and password: *DaVinci*.

d) Click on the Create button and the imported local project library will appear in the Network section of the Project Libraries sidebar.

Duplicating a Network Project Library

You can also duplicate a network project library as an additional backup, or save point in a large project.

To duplicate a network project library:

1 Select the project library you want to duplicate.
2 Click the Display Project Library Details icon (the circled letter "i" to the right of the project library).
3 Select the Duplicate button.
4 Choose a new unique name for the duplicated library and click OK.

Optimizing a Project Library

Sometimes, project libraries in DaVinci Resolve can become so large that their size affects performance. In these cases you may need to optimize them to improve access speed by "vacuuming" the project library of unnecessary spaces and reindexing it. Using the Optimize command can also be a valuable troubleshooting step in certain cases where you're having problems opening, importing, or otherwise using projects saved within network project libraries.

To optimize a project library:

1 Select the project library you want to optimize.
2 Click the Display Project Library Details icon (the circled letter "i" to the right of the project library).
3 Click the Optimize button.
4 A warning dialog will appear. Click Optimize to proceed, otherwise click cancel to leave the project library in its current state.

Sharing a Key to a Network Project Library

If you wish, you can share your access key to a network project library with another user on the same local network.

To export a key to a network project library:

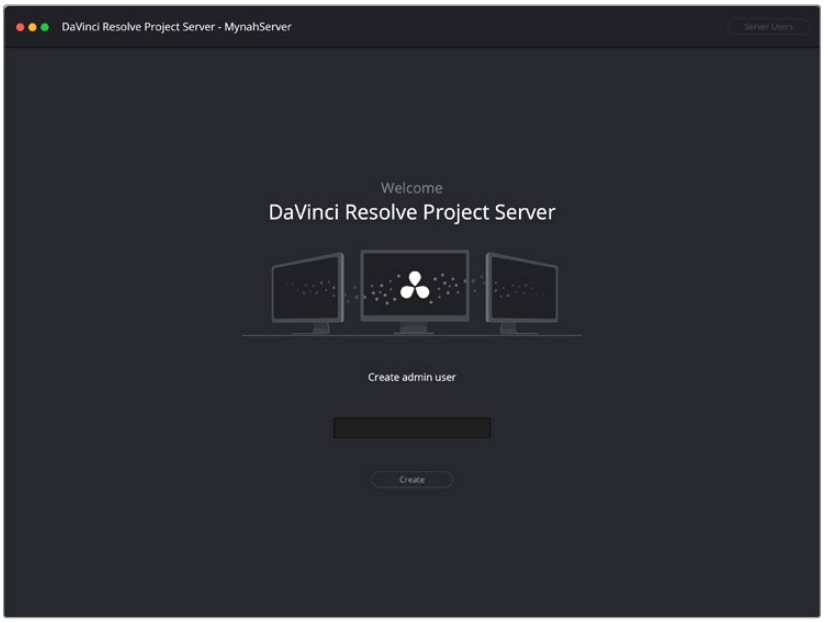
1 Click on the Show/Hide Project Libraries icon in the upper left of the Project Manager to expose the sidebar.
2 Select the Network icon from the Project Library options.
3 Select the project library you want to share the key to.
4 Click the Display Project Library Details icon (the circled letter "i" to the right of the project library).
5 Click the Share Key button.
6 Select the directory in your file system where you want to save the key to and click save.
7 Send the resulting .resolvedbkey file to the other user.

Using the DaVinci Resolve Project Server Application

DaVinci Resolve Project Server is a stand-alone application that lets you create, manage, backup, restore, and most importantly share project libraries on any workstation. Using this application, it's not necessary to launch DaVinci Resolve just to manage your project libraries.

Installing the DaVinci Resolve Project Server

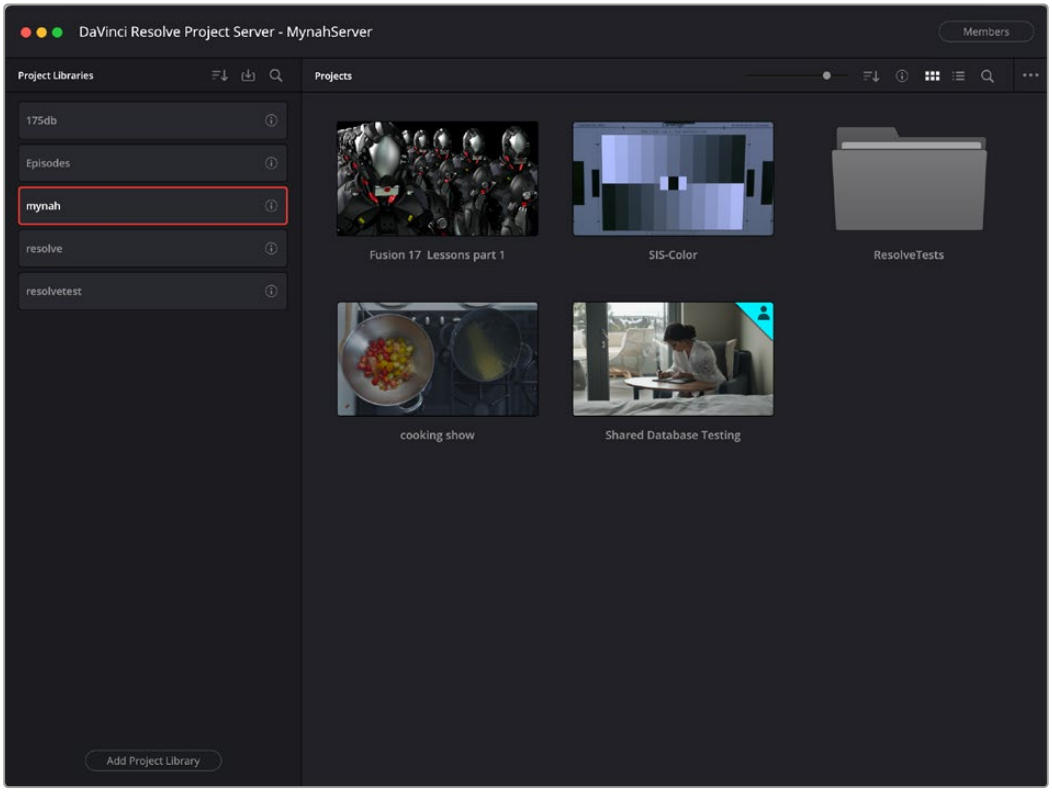
The hardware and software setup required to install the DaVinci Resolve Project server is outlined in the User's Guide document included in the program download. On initial startup, you will be presented with a screen to set up an Admin account for the server. This account will give you full permissions to adjust any aspect of the project libraries and make changes to the Project Server itself.



On initial startup, the DaVinci Resolve Project Server will ask you to create an administrator account.

The DaVinci Resolve Project Server Interface

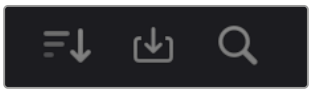
The DaVinci Resolve Project Server interface greatly resembles the DaVinci Resolve Project Manager with the Project Libraries sidebar open. However, it exposes all of the project library management tools that are available for creating and managing project libraries, including controls for sharing project libraries and creating access keys that are essential for quickly and easily creating and connecting to Project Servers.



The DaVinci Resolve Project Server window

This window has three main UI areas:

- **Project libraries list:** The Project libraries list in the Project Server application shows every single DaVinci Resolve network project library on your machine; even ones that have been disconnected. This makes it easy to find project libraries that you want to reconnect.
- **Projects browser:** Shows all projects and folders within the currently selected project library as icons or as a hierarchical list.
- **Toolbar:** A toolbar at the top of the window shows you functions that are available for managing DaVinci Resolve project libraries on your workstation.

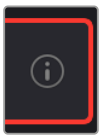


Project Libraries toolbar controls
(L-R): Sort, Restore, Search

The three controls at the top of the Project Libraries toolbar have the following functions:

- **Sort Order dropdown menu:** This menu lets you choose how to sort the various local and network project libraries displayed in the sidebar. You can sort by Database Name, Schema (by date), Status, or Location in Ascending or Descending order.
- **Restore:** Imports .resolve.backup files to restore a backed up project library.
- **Show Search Field:** Displays a search field and search criteria dropdown that lets you search for project libraries in the sidebar by Name, Schema, Status, or Location.

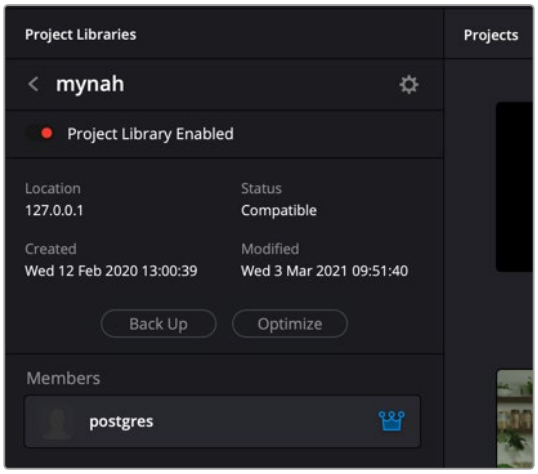
Clicking on the Display Project Library Details icon (the circled letter “i” to the right of the project library), shows additional information underneath each database in the sidebar, and exposes the Backup and Optimize buttons.



The Display Project Library Details icon

The controls exposed in the Project Library details have the following functions:

- **Project Library Settings:** Clicking on this gear icon allows to choose to Rename, Delete, or Export an Access Key for the library.
- **Project Library Enabled:** This toggle enables or disables the project library sharing.
- **Project Library Information:** Displays metadata about the library, such as Location (IP address of the Project Server), Status (compatible or upgrade required), and the created and modified dates.
- **Backup:** Selecting this button lets you export the project library to a backup file.
- **Optimize:** Selecting this button lets you optimize the project library for better performance.
- **Members:** This area shows you which members have access to the project, and the Manage Members button lets you add or remove their access.



Project Library details exposed

Creating New Network Project Libraries

If necessary, you can create new network project libraries right within the DaVinci Resolve Project Server.

To create a new network project library:

1. Click the Add Project Library button at the bottom of the Project Libraries list.
2. When the Create Project Library window appears, type a name for the new project library into the Name field. Because all projects in a network project library are saved internally within the network project library, no other changes are necessary.
3. Click Create, and the new network project library will appear in the Project Libraries list.

Backing Up and Restoring Project Libraries

You can also back up and restore project libraries without needing to open DaVinci Resolve. Furthermore, you can back up project libraries from older versions of DaVinci Resolve, making it easy to back up project libraries for safety before you upgrade them.

To backup/export a project library:

1. Select the project library you want to back up.
2. Click the Display Project Library Details icon (the circled letter “i” to the right of the project library).
3. Click the Back Up button.
4. Choose a location to which to save the backup in the Backup Project library dialog, and click Save.

To restore/import a project library:

1. Click the Restore button at the top of the Project Libraries sidebar.

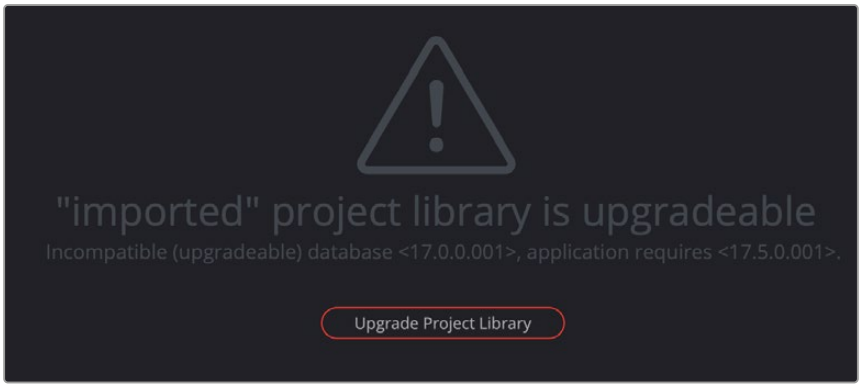
The Restore button

2. Find the project library you need to import using the file import dialog, and click Open.
3. In the Add Project Library dialog, type a name for the new project library into the Name field. This will rename the imported project library but will not alter its contents. You can also name it the same as the original project library.
4. Click Create, and the imported local project library will appear in the Project Libraries sidebar.

Upgrading Project Libraries

From time to time, new versions of DaVinci Resolve require changes to the way projects are created, which requires project libraries created with older versions of DaVinci Resolve to be upgraded before you can access the projects within. Fortunately, this is a simple process.

It’s generally a good idea to back up a project library prior to upgrading it, in case something goes wrong. In general, upgrading from a whole version release to the next whole version release of DaVinci Resolve usually requires an upgrade, while upgrading to a dot release of the same version may or may not. If the currently used project library requires an update, you’ll be told on application startup.



The upgrade warning in the Project Manager indicates that project library needs to be upgraded

To upgrade a project library from an older version of DaVinci Resolve:

Click on a project library that needs updating, and select the Upgrade Project Library button. A dialog appears to confirm if you really want to upgrade that project library. Click Upgrade to proceed.

Viewing Project Library Contents

If you're using multiple project libraries to organize your projects, you can browse the contents of each project library to search for what you're looking for. Simply click to select a project library in the sidebar, and an orange highlight will appear. All projects corresponding to that project library appear in the Project Manager window.

Optimizing Project Libraries

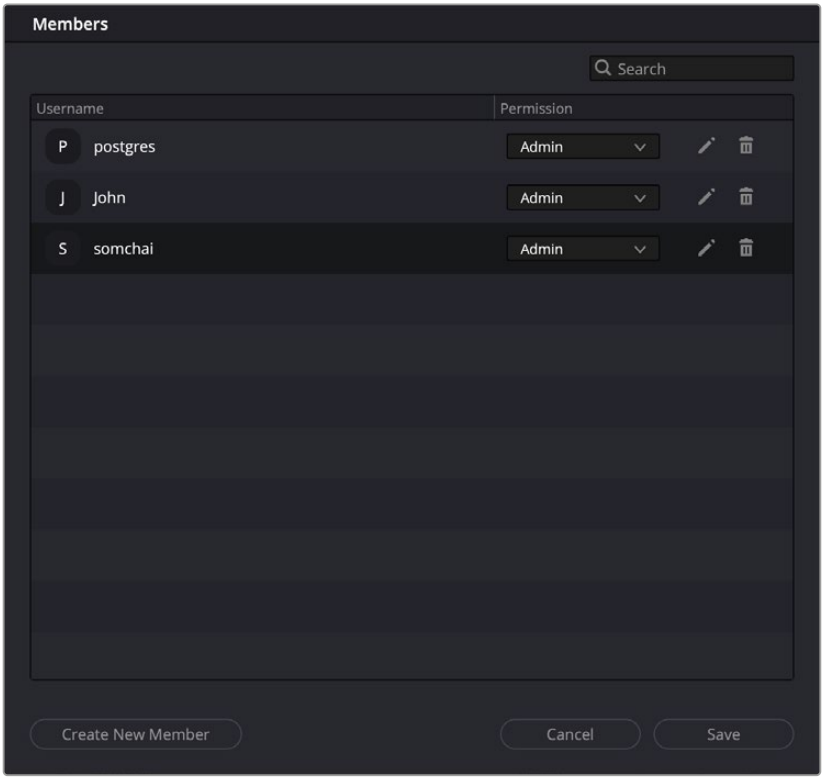
Sometimes, project libraries in DaVinci Resolve can become so large that their size affects performance. In these cases you may need to optimize them to improve access speed by "vacuuming" the project library of unnecessary spaces and reindexing it. Using the Optimize command can also be a valuable troubleshooting step in certain cases where you're having problems opening, importing, or otherwise using projects saved within network project libraries.

To optimize a project library:

1. Select the project library you want to optimize.
2. Click the Display Project Library Details icon (the circled letter "i" to the right of the project library).
3. Click the Optimize button.
4. A warning dialog will appear. Click Optimize to proceed, otherwise click cancel to leave the project library in its current state.

Member Management in the DaVinci Resolve Project Server

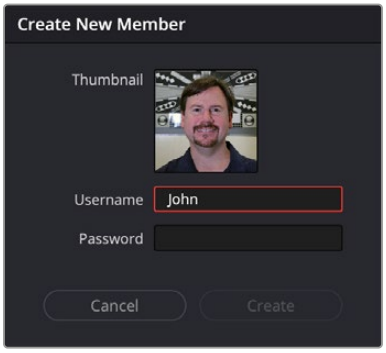
It is possible to assign specific users to specific project libraries and adjust their roles. This gives extra granularity for security for complex projects with many users. Every network project library starts with the default user: postgres and password: DaVinci. This was until recently the only way to sign into the DaVinci Resolve Project Server remotely, but now you can add custom users and passwords as well. Members will be able to use their individual credentials to sign into network projects in the Project Manager.



The DaVinci Resolve Project Server Members management window

To add a new member to the DaVinci Resolve Project Server:

1. Click the Members button on the top right of the DaVinci Resolve Project Server.
2. Click the Create New Member button at the bottom of the Members window.
3. Select a username and password for the member, you can optionally add a thumbnail photo as well. This thumbnail will be used to identify the user in collaboration mode.



The DaVinci Resolve Project Server
Create New Member window

4. Repeat as for as many new users as you want to add.
5. Click the Save button to store the new users, or click Cancel to discard your changes.

To delete an existing member from the DaVinci Resolve Project Server:

1. Click the Members button on the top right of the DaVinci Resolve Project Server.
2. Find the user you want to delete and press the trash can icon in that user's row. There is no warning dialog for the deletion, and it is not undoable, so make sure you double check that you have selected the correct user.

To modify an existing member's permissions in the DaVinci Resolve Project Server:

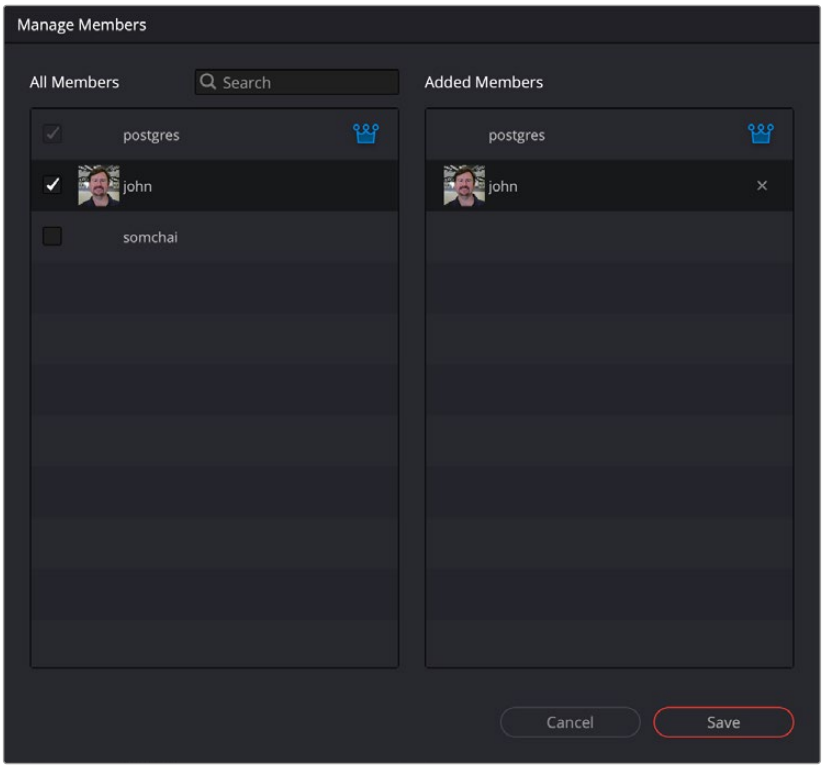
1. Click the Members button on the top right of the DaVinci Resolve Project Server.
2. To change the user's role between Administrator and Collaborator use the selection menu.
3. To edit a user's name and password details select the Pencil icon.

Assigning Members to Specific Project Libraries

Once you have created some members, you can add them to specific project libraries. This lets you have multiple teams of people, working on multiple projects off the same Project Server, without the off chance that they accidentally delete another teams projects, or have access to sensitive material.

To add or remove a member from a specific project library:

1. Open a project library's details settings by clicking on the "i" icon to the right of its name.
2. Click on the Manage Members button at the bottom of the project library.
3. To add a member, check the box next to their name in the All Members field.
4. To remove a member, click on the "x" next to their name in the Added Members field.



The DaVinci Resolve Project Server Mange Members window

Members added to a project library in this way will be able to log-in using their credentials in the Network Libraries section of the Project Manager in DaVinci Resolve.

Sharing Network Project Libraries via the Project Server

You can also use the DaVinci Resolve Project Server to easily set up a shared Project Server on your local network. However, for this to work, you need to adhere to the following requirements:

- All workstations need to be connected to the Project Server on a local network.
- All network connections should be reasonably fast (preferably Gigabit Ethernet or faster).
- The computer functioning as the Project Server should be reasonably fast, but it doesn't need fast GPU processing.

The following procedures describe how to set up a shared Project Server, and how to export an access key with which to easily set up other workstations to connect to it.

To configure the DaVinci Resolve Project Server:

1. Open the DaVinci Resolve Project Server application.
2. In the File > Network Interface menu choose the IP address you wish to use to connect to the client workstations.

The Network Interface menu

IMPORTANT: You must select the appropriate Network Interface IP address that matches the network the client computers are on before you create and share a project library or create an access key, otherwise a connection error will occur.

To share a project library using the DaVinci Resolve Project Server:

1. Select or create a DaVinci Resolve project library you want to share, and click the Project Library Enabled slider on. It's at the top of the project library's details section.
2. When a dialog appears asking if you want to authorize the configuration of your Project Server, click Authorize. That project library can now be shared among other DaVinci Resolve workstations on the same network.

Once you've set up a Project Server, it's easy to connect other machines to that server using access keys that you can create using the DaVinci Resolve Project Server application.

To create an access key to enable easy connection to a Project Server:

1. Select a project library that you've set up to share, enter the library's details section, and choose the Export Access Key option from the settings icon in the upper right.
2. Choose a location via the Create Access Key dialog, and click Save. An access key file is saved to the location you chose with the file extension .resolvedbkey.
3. Copy the .resolvedbkey file to the workstation you want to connect to the shared project library.

4 Open DaVinci Resolve, and when the Project Manager appears, open the Project Libraries sidebar, and then drag the .resolvedbkey file and drop it anywhere within the Project Manager. The shared project library should now appear in the Project Libraries sidebar, and if you select it, you'll see all of the projects that are located in that project library on the Project Server.

   If necessary, you can also disable sharing for any project library, preventing remote access to it from other workstations on the network.

To disable sharing:

1 With the DaVinci Resolve Project Server application open, select a project library you enabled sharing for, and click the Project Library Enabled slider off. It's at the top of the project library's details section.

2 When a dialog appears asking if you want to authorize the configuration of your PostgreSQL server, click Authorize. That project library will no longer be shared.

IMPORTANT: If you enable sharing on a computer that is later moved to another network (for example, if you set up Project Server sharing on a laptop), you'll need to disable sharing and then re-enable it before you create access key files that will successfully connect to the new network location.

Cloud Project Libraries

Cloud project libraries are hosted on Blackmagic's Project Library servers on the internet, allowing DaVinci Resolve users to connect and collaborate on the same projects from any location in the world.

For more information on Cloud Project Libraries, *see Chapter 188, "Blackmagic Cloud Project Server."*

Chapter 193

Collaborative Workflow

Multi-user collaborative workflow uses “bin locking” to manage who has access to what when multiple collaborators open the same project.

However, collaborative workflow also allows multiple artists to do simultaneous editing, compositing, grading, and metadata entry to clips on the same timeline within a single project for which Collaboration has been enabled. Multiple users can simultaneously access the same timeline within the same project to edit, composite, and grade at the same time, while other editors and assistants can open different bins containing different timelines within the same project to do editorial and media management. This chapter describes how to set up multiple DaVinci Resolve workstations to collaborate, and how to use bin locking to work together.

Introduction to Collaborative Workflow

Multi-user collaborative workflow allows simultaneous editing, compositing, grading, and Media Pool clip management by multiple people within a single project that has been enabled for collaboration. Collaboration takes three different forms:

- Using bin locking, multiple editors can simultaneously edit different timelines in different bins of the same project, while assistant editors can reorganize clips and edit the metadata in other bins within the same project. Bins are automatically locked when selected by a particular user and unlocked when deselected by that same user, or they can be manually set to be either locked or unlocked as circumstances require.
- Using clip locking, multiple colorists and compositing artists can work together in the same timeline, in either the Color page or Fusion page, without fear of overwriting one another's work. A clip is locked automatically when a user selects that clip to work on, and is unlocked (with the work checked in) when that same user selects a different clip. Clip locking in the Fusion page is maintained separately from clip locking on the Color page, so a compositing artist and colorist can work together on the same shot.
- One editor, one compositing artist, and one colorist can work together on the same clip in the same Timeline of the same project without conflict.

Overall, working in DaVinci Resolve in Collaborative Workflow mode is identical to working in non-collaborative mode. However, there are a few collaborative capabilities that are worth knowing about.

Collaborative Render Cache Support

Each collaborator on a project will have the exact same render cache format settings automatically configured across all machines. If you are collaborating across operating systems (Mac, Windows, Linux), it is important that the Render Cache Format is set to a codec that is supported by all platforms.

Collaborative Support for Individual Monitoring

If necessary, each collaborator on a project can override the output and monitoring settings of a project on their particular workstation. When a project is set to use Collaborative Workflow, a "Use Local Overrides" checkbox appears in the Video Monitoring group of the Project Settings that lets you choose how to monitor on your particular workstation.

Collaborative Marker, Flag, and Clip Color Support

Collaborative workflow supports the modification of markers, flags, clip metadata, and clip color from the Color page. Additionally, FrameIO comment markers are supported by collaborative workflow.

Read Only Mode

Users can load collaborative projects in Read Only Mode.

Collaborative Support for HDR

Starting with DaVinci Resolve 16, there is support for Dolby Vision and HDR10+ in collaborative workflows.

Requirements for Collaboration

In order to use collaborative workflow:

- All users must be working on a project that's been saved either in the Blackmagic Cloud, or on a properly configured remote project library server. This remote project library server can be on one of the actively used DaVinci Resolve workstations, or it can be another computer on your network that simply hosts shared projects, but it should be on a computer that is never shut down or put to sleep, to prevent projects suddenly becoming unavailable.
- All machines participating in a collaborative workflow must be networked. They can be on the same local area network (LAN), but you can also connect computers on different subnets.
- Shared projects should ideally use media on some type of fast storage area network (SAN), with each collaborator connected to that SAN so that every workstation that's connected to the project being collaborated on has direct access to the same media. In a pinch, shared volumes over a network will work, but proper SANs will provide significant performance benefits. Facilities using multiple computer platforms (macOS, Windows, and Linux) together can use the Mapped Mount option of the Media Storage Locations list, found in the DaVinci Resolve System Preferences, to facilitate cross platform drive connection.
- Alternatively, all workstations can be connected via the internet to the same cloud storage folder with the proper Path Mapping set up in the Project Settings.

For more information on setting up a project library server, *see Chapter 192, "Managing Project Libraries and Project Servers."*

Enabling Multiple User Collaboration

Enabling Multiple User collaboration mode on a project is required to use the collaboration toolset.

To open a project and initiate a collaborative workflow:

1. Open DaVinci Resolve on a computer that's connected to a remote project library or Blackmagic Cloud server.
2. Open any project on the remote project library DaVinci Resolve is connected to using the Project Manager.
3. When the project is open, choose File > Multiple User Collaboration.

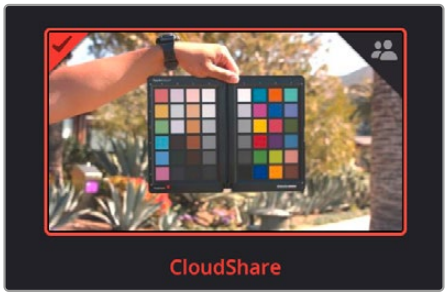
   Once collaboration is enabled, two additional buttons appear at the lower-right corner of the DaVinci Resolve interface, next to the Project Manager and Project Setting buttons. These are the Collaboration Chat and Collaboration buttons.

The Collaboration Chat button (far left) and the Collaboration button (second from left)

NOTE: When you enable collaboration, the “Auto conform missing clips as media is added to Media Pool” option in the General Options panel of the Project Settings is automatically disabled, as it interferes with collaborative workflow. Also, Live Save is automatically turned on in the Auto Save panel of the User Preferences, to ensure that all collaborators’ work is saved regularly to avoid conflicts between collaborators.

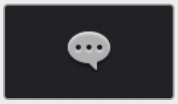
Opening Projects to Collaborate

Projects that have Collaboration enabled appear with a badge on their thumbnail in the Project Manager to let you know that project is available for collaboration.



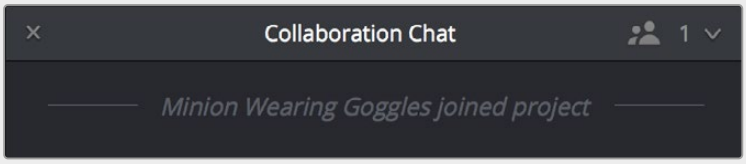
An icon indicates that a project in the Project Manager is available for collaboration

At this point, anyone else who has access to this remote project library server can simply open this project up and work collaboratively with you. Whenever a collaborator opens the same project you’re working in, the Collaboration Chat button at the bottom of the DaVinci Resolve UI highlights to let you know you have a message.



The Collaboration Chat button highlights to let you know you have a message

Opening the Collaboration Chat window shows who’s collaborating with you.



A new message in the Collaboration Chat window lets you know who else has opened the project you’re working on

Customizing Your Collaborator Identification

Once you've set up a project for collaboration, you want to make sure it's easy to tell all your collaborators apart. Clicking the Collaboration button opens a list of all collaborators, or project members, working in that project.

Opening the Collaboration list shows all the current project members

The top member is you, and you can change the name you use by editing the text field. Your user icon is set automatically based on the image you chose either in your Blackmagic Cloud account or the DaVinci Resolve Project Server. If you haven't chosen an image, it defaults to the first two letters of your user name. Additionally, you can see the other member's workstation OS revealed as an icon to the right of their name.

How Collaboration Works

At its simplest, collaborative workflow uses a "first come, first served" model to manage who has can make changes to what. Essentially, the first collaborator to select a bin in the Media Pool, open a timeline, or select a clip in the Fusion page or Color page gets a "lock" on that item. Once an item is locked (indicated by a colored collaborator badge), other collaborators can look at it, but they cannot make changes. This prevents versioning conflicts from occurring.

Bin and clip locks are released when a collaborator selects a different bin or timeline in the Media or Edit pages, or a different clip in the Fusion page or Color page. At that point, the changes that have been made to the previously locked item are "checked in" and made available to all collaborators once they refresh their project (by clicking a circular refresh icon that appears to the right of bins in the Media Pool or in the corner of the Edit page Viewer).

All changes that collaborators make are automatically saved to the project as they're made, so no work will ever be lost as you collaborate with your team. However, each collaborator gets to decide when they want to update the bin, timeline, or clip they're currently working on to see the changes made by everyone else, in order to prevent a kaleidoscope of constant alterations to compositions and grades from being a distraction while you're working.

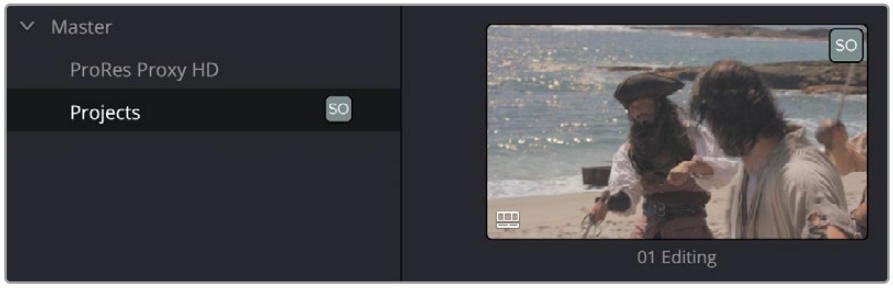
The following sections describe Bin and Timeline locking and Clip locking in more detail.

Automatic Bin and Timeline Locking

Whenever a collaborator opens a particular bin, that bin and its contents are locked, preventing any other collaborators who open that project from making alterations to anything inside that same bin. This prevents versioning conflicts while work is in progress. When a bin is locked, you can still view its contents, if for instance you just need to figure out where a particular clip has been put, but you can't make changes.

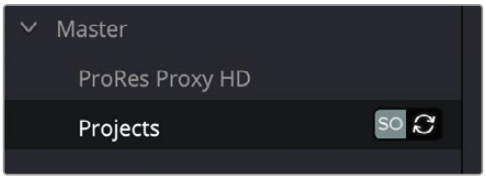
Collaborators can open locked bins and see the contents for reference, but they cannot make any organizational or editorial changes. The only things that can be changed once a bin and its contents are locked are the creation or alterations of clip compositions in the Fusion page, and alterations to clip grades in the Color page.

You can always tell when a collaborator has a lock on a bin and its contents because a badge appears to the right of the bin in the Bin list, and in the corner of timeline thumbnails that are visible in the Media Pool browser area. Hovering the mouse over that badge in the Bin list reveals a tooltip with that collaborator's name.



An icon indicates that another collaborator has a lock on the Projects bin.

Once a collaborator (someone other than you) makes changes to a bin's contents or to a timeline, you'll see a circular "refresh" badge appear by each affected bin in the Bin list of the Media Pool, alongside their collaborator icon. Click these badges whenever you want to update your version of the shared project with all organizational and editorial changes made by others in that bin.



An icon indicates that another collaborator has made changes; clicking it refreshes your project to show those changes

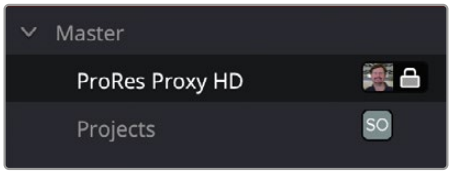
To release a bin or timeline, simply select another bin or timeline. It's that simple.

Managing Bin Locks Manually

You can also manually control the locked state of bins, during instances where you want to keep bins locked for future use or prevent them from becoming locked when you only want to browse the contents.

Keeping Bins Locked

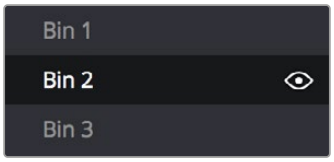
If you want to lock one or more bins that you know you're going to be switching among to either prevent other collaborators from making changes or so that nobody else inadvertently prevents you from having access, you can right-click one or more selected bins and choose Lock Bins to lock them. Bins locked in this way remain locked, even when you deselect them, until you right-click them again and choose Unlock Bins. Other users will see your collaboration icon as well, so they will know who currently has the bin locked.



Manually locked bins stay locked even when they're not selected

Keeping Bins Unlocked

Additionally, you can choose to keep bins unlocked when selected. For example, you may just want to examine the contents of a bin without keeping someone else from editing its contents. In this case, simply Option-click any bin to open that bin in read-only mode, which is indicated by an eyeball badge to the left of that bin in the Bin list. In this mode, any other collaborator can still lock that bin while you're examining its contents. Selecting any other bin will clear this read-only status.



Selecting a bin in read only mode allows collaborators to lock that bin while you examine its contents

TIP: While a bin is open but manually unlocked by you, you can still open clips into the Source Viewer and add markers to them, so long as another user doesn't select that same bin and lock you out.

Manually Locking and Unlocking Timelines

You can also manually manage the locking of timelines. Opening a timeline automatically locks other collaborators out of making changes to that timeline, but it does allow other users to modify the bin that timeline appears within. This allows for greater flexibility in setting up your Media Pool and avoids locking media or other timelines in the same folder. You can still manually choose to lock individual Media Pool bins to secure their contents independently.

To unlock a timeline to let other collaborators work on it:

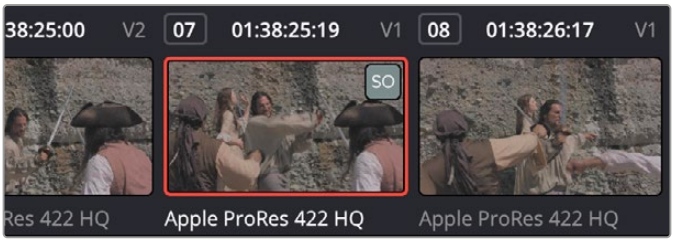
- Right-click that timeline in the Media Pool and choose Timelines > Unlock Timeline from the contextual menu.

To lock a timeline preventing other collaborators from working on it:

1. Right-click that timeline in the Media Pool and choose Timelines > Lock Timeline from the contextual menu.
2. Other collaborators will be unable to modify the timeline while you have a lock on it, however they will be able to modify any other clips and timelines in the bin.

Automatic Clip Locking

Clip locking in the Fusion and Color pages works similarly. As multiple compositing artists work in the Fusion page, and multiple colorists work in the Color page, the first compositing artist or colorist to select any given clip has an automatic lock on that clip. Other compositing artists or colorists will see a badge on that clip in the Thumbnail timeline showing that it's locked as well as letting them know who has the lock. In the following screenshot, the SO badge in the corner of clip 7 in the Color page Thumbnail timeline indicates that clip is locked.



Badges in the Thumbnail timeline indicate which clips are locked because a collaborator is grading them

Automatically Checking In Work When You Change Clips

When you're finished with the clip you're working on, you need only select another clip for the changes you made to the previously selected clip to be automatically saved and pushed to all other colorists who are working on that timeline in the Color page. No refresh is needed. This is the main difference between clip locking in the Color page and bin locking.

Compositing Artists and Colorists Can Work Together

The Fusion page and Color page each maintain separate clip locks. This means that for any given pool of compositing artists, only one will be able to work on a given clip at a time, while in the Color page only a single colorist will be able to work on a clip at a time.

However, because Fusion and Color page clip locking is maintained separately, that means that one compositing artist and one colorist can work on a single clip in the timeline simultaneously, even while an editor is working on that timeline.

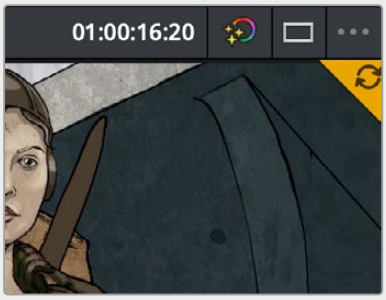
Receiving Changes Made by Collaborators

As you work collaboratively, it will be common for groups of compositing artists to be executing multiple compositions at a time, while colorist and their assistants will be working on the grade, and an editor and their assistants will be refining the edit, all working together within the same project.

Receiving Changes On the Edit Page

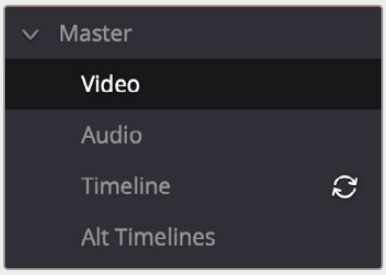
While compositors are compositing and colorists are grading clips within the same timeline of the same project, each clip that's adjusted in the Fusion or Color page triggers a Refresh badge to appear in three areas of the Edit page, so the collaborating editor(s) can decide when to update their timeline to see the changes that have been made.

At the upper-right corner of the Timeline Viewer. Clicking this badge refreshes the composites and grades of all clips in the currently open Timeline.



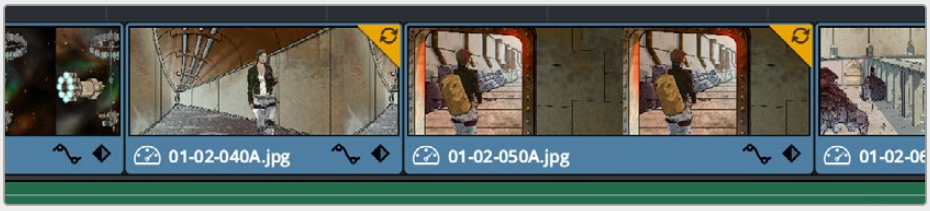
A clickable "update" badge appears in the corner of the Timeline Viewer for timelines with edits, grades, and composites that have been updated

At the right of the bin containing the modified timeline in the Media Pool's bin list. Clicking this badge refreshes all clips in the Timeline within that bin.



A clickable "update" badge appears over bins containing timelines in the Media Pool with edits, grades, and composites that have been updated

At the upper-right corner of each modified clip in the Timeline.

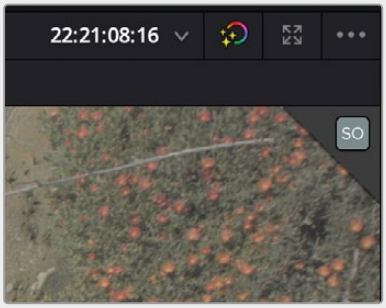


A clickable "update" badge appears over clips in the Timeline with edits, grades, and composites that have been updated

Receiving Changes On the Fusion and Color Pages

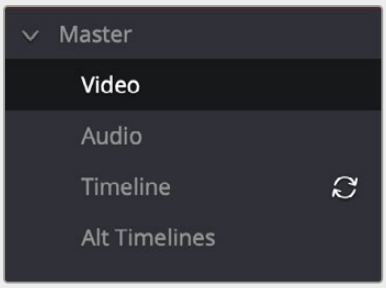
For collaborators working on the Fusion or Color pages, other badges indicate when editors have made changes to the Timeline, or when other compositing artists or colorists have made changes to other clips in that timeline.

Timelines that you're locked out of because another collaborator has a lock on them are indicated by a badge at the upper-right corner of the Viewer, while changes made to the Timeline by editors on the Edit page are indicated by a refresh badge in the same location. Clicking this badge refreshes all clips in the Timeline.



A badge in the Viewer shows that a viewer has a lock on this timeline

If you open up the Media Pool, then a badge appears at the right of any bin in the Bin List that's been reorganized or that contains a modified timeline. Clicking this badge refreshes all clips in the Timeline within that bin.



A badge appears to the right of bins in the Media Pool containing timelines that have been updated

A badge appears at the upper-right corner of each clip in the Thumbnail timeline that's been modified by a fellow compositing artist or colorist. Clicking a single clip's badge updates that clip alone.

A badge appears over clips in the Timeline with grades that have been updated. Clicking this badge refreshes just that clip.

Examples of Collaborators Working Together

The first collaborator that opens a timeline is the only person that can make editorial changes to that timeline in the Edit or Fairlight pages. Other collaborators who open that project are “locked out” of making changes to the Edit or Fairlight pages, but they can see the Timeline, and they can make grading changes in the Fusion or Color pages. This means in situations where you want multiple editors to be working on a project, it can be ideal to organize your program into separate “reels,” where each reel of a project is a separate timeline in a separate bin.

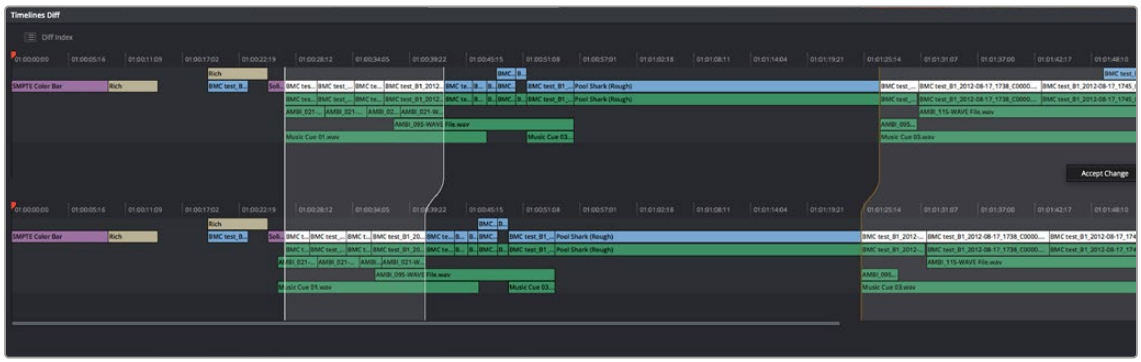
Multiple Editors Working Together

The first collaborator that opens a timeline is the only person that can make editorial changes to that timeline in the Edit or Fairlight pages. Other collaborators who open that project are “locked out” of making changes to the Edit or Fairlight pages, but they can see the Timeline, and they can make grading changes in the Fusion or Color pages. This means in situations where you want multiple editors to be working on a project, it can be ideal to organize your program into separate “reels,” where each reel of a project is a separate timeline in a separate bin.

On the other hand, if two or more editors must both work on the same timeline, this can be accomplished using duplicate timelines and then merging the changes back together later on. For example, collaborating editor Anne can do the following to make changes to a timeline that editor Erin is already working on:

- First, Anne can duplicate the locked timeline into a separate bin from the one Erin has a lock on. Alternately, Erin could be proactive and duplicate the timeline into a separate bin in advance.
- Second, Anne will re-edit the duplicate timeline to make whatever changes are necessary to a different scene than the one Erin is currently working on. Working on different scenes is the cleanest and easiest way of using this workflow.
- Third, Anne uses Collaborative Chat to notify Erin that the changes are finished.
- Fourth, Erin then refreshes the project to see Anne’s updated duplicate timeline in the Media Pool, right-clicks it, and chooses Compare With Current Timeline from the contextual menu to show the Timeline Comparison window that makes it possible to merge the changed section of the duplicate timeline with the original timeline that Erin already has open.

In the following screenshot, Erin’s highlighted changes (made while Anne was working) can be seen at the left, and Anne’s highlighted changes can be seen at the right. Right-clicking within the right highlighted area reveals an Accept Change command that lets that scene’s changes be merged from the duplicate timeline back to Erin’s original timeline.



Using the Compare With Current Timeline command lets you see the differences between two differently edited versions of the same timeline, and merge a scene's worth of changes that a collaborator has made (at right) back to the original timeline

For more information on comparing timelines, *see Chapter 34, "Creating and Working with Timelines."*

Editors and Assistant Editors Working Together

Collaborators can edit metadata, create new bins, and reorganize clips within unlocked bins only. This means that your project should be organized so that an editor can lock the contents of the bins they need to work with at a given point in time, while the assistants can work on additional timelines and media within other bins in that project.

However, in addition to being able to copy timelines from a locked bin to a bin that you control, you can also copy clips from one timeline to another. In this way, if you absolutely need to make changes to source clips while the original source clips are locked, you can make your changes to copies of these clips.

Editors and Compositing Artists Working Together

Editors and compositing artists can work together closely, since compositing artists can create compositions for one or more clips in a timeline while it's being edited, even though that timeline and the bin it's in are locked to other editors.

Here's an example of an editor working on a commercial spot with a lot of greenscreen material working together with one or more compositing artists.

- First, the editor cuts together each foreground clip with actors performing as a rough cut, and once that rough cut is assembled, they edit in the background clips that accompany each greenscreen clips to create a series of stack of clips.
- Second, the editor selects each stack of clips, one by one, and uses the New Fusion Clip command to create Fusion clips that the compositing artists can work on. By making each of these clips into Fusion clips, the editor is making it easy for the compositing artists to have access to all the clips necessary for each composition from within the Fusion page, collaboratively.
- At this point, the editor uses collaborative chat to notify the compositing artists that there are composites ready for them to work on, and the editor can then turn their attention back to refining the edit.
- Upon being notified that they can begin work, one or more compositing artists start working through the Fusion clip compositions while the editor is working, to create each multi-layered composite that's necessary. As each compositing artist finishes a clip and moves to a new clip

to begin work, the editor sees a notification badge at the upper-right corner of each clip in the Timeline that's been composited, as well as notification badges in the Bin List of the Media Pool, and at the upper-right corner of the Timeline viewer. Clicking any of these badges will refresh one or more of these clips, so the editor can see the changes.

Multiple Compositing Artists Working Together

To prevent versioning issues, only one compositing artist can work on a particular clip at a particular time in the Fusion page, and the first compositing artist to select a clip puts a lock on that clip. Other collaborators looking at the Thumbnail timeline in the Fusion page will see a small icon that shows it's locked, letting them know they can't make any changes to it until whoever is working on that composition moves to another clip.

A small icon indicates that you're locked out because another compositing artist is working on that clip

This means that multiple compositing artists can't work on the same composition at the same time. However, an assisting compositing artist can do preparatory work on one composition, such as doing rotosocoping, paint, particle system design, or any other time-consuming task, while a lead compositing artist works on another shot in the meantime. Once the assisting compositor is done, they can select another clip to work on and use collaborative chat to let the other compositor know they're done and that clip is ready for more work.

In order to prevent half-finished work from being disseminated to other collaborators, a clip that's in the process of being worked on in the Fusion page isn't updated for anyone else who's working on that same timeline until the compositing artist who's working on it selects another clip. Immediately upon being deselected, all changes are automatically checked in and made available to all other collaborators, who see notification badges in the Fusion page and the Edit page to alert them that changes are available and that they can refresh their timeline to see the updates.

Editors and Colorists Working Together

Colorists and editors can work together very closely in DaVinci Resolve, as colorists can grade the shots of a timeline that an editor is currently working on, even though that timeline and the bin it's in are locked to other editors.

From the colorist's point of view, whenever the editor makes an alteration to the Timeline, a badge appears at the upper-right corner of the Color page Viewer to indicate that a change has been made to the timeline being graded. Clicking this badge updates the timeline the Colorist is working on.

In order to prevent half-finished work from being disseminated to the editor (or worse, being seen by the client), clips that are in the process of being graded aren't updated for other collaborators that are looking at that timeline until the colorist who's working on it "checks in" their work by selecting another clip. So, from the editor's point of view, whenever a colorist has finished grading a clip and has selected another clip to grade, a series of badges appear in the Edit page, one on the clip that's been graded, one on the Timeline Viewer and one on the bin in the Bin List that contains the Timeline. Clicking any of these badges updates the Timeline with the latest grades.

Multiple Colorists Working Together

Only one colorist can work on a particular clip at a particular time, and the first colorist to select a clip puts a lock on that clip. Other collaborators looking at the Thumbnail timeline in the Color page will see a small icon that shows it's locked, letting them know they can't make any changes to it until whoever is grading that clip moves to another clip.

A small icon indicates that you're locked out because another colorist is grading that clip.

In order to prevent half-finished work from being disseminated to other colorists or editors, a clip that's in the process of being graded isn't updated for other collaborators that are looking at that timeline until the colorist who's working on it selects another clip. These changes are then automatically made available to all other collaborators working in the Color page, who see badges appear in the Edit and Color pages to indicate which clips have updates available.

This makes it easy for multiple colorists to work together. For example, an assistant colorist can be notified via Collaborative Chat to draw a custom window that a senior colorist needs for a grade. The assistant opens that timeline in another suite, selects the appropriate clip, and draws the window. Once finished, the assistant simply selects a different clip, and the changes they've made are immediately available to the senior colorist, who sees a badge on that clip in the Thumbnail timeline and can click to update it.

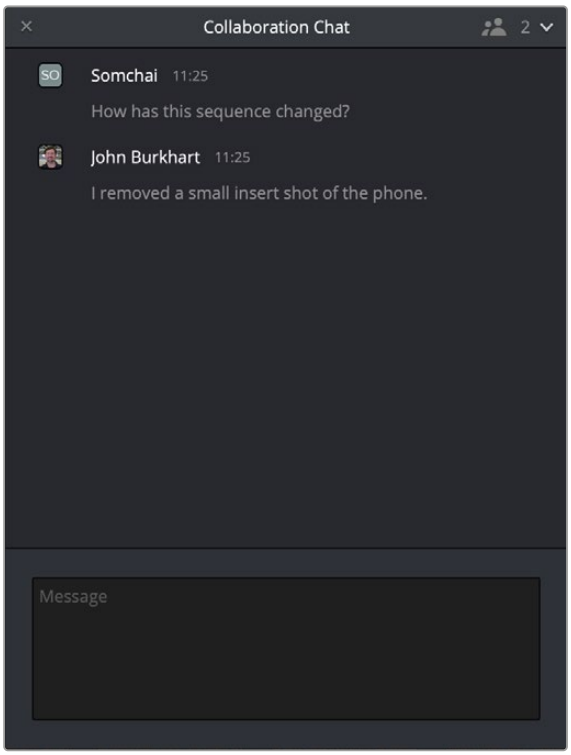
Managing Notes Among Collaborators

If an editor wants to send a note to colorists or compositing artists, they can do one of the following:

- They can add a marker with note text to the Timeline ruler (the marker appears in the marker submenu in the Color page Viewer option menu)
- They can add a marker with note text to a clip (that marker appears in the mini-timeline of the Color page)
- They can color code clips in different ways to get the colorist's attention (clip color coding appears as a dot in the Thumbnail timeline).
- Of course, the editor and colorist can always interact via the collaborative chat window, as well.

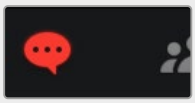
Collaboration Chat

To facilitate communication among collaborators, DaVinci Resolve has built-in text chat, called Collaboration Chat. Simply click the Collaboration Chat button to open the chat window, and chat away.



The Collaboration Chat window for communication among collaborators

The Collaboration Chat button at the bottom of the DaVinci Resolve interface highlights orange whenever someone texts while this window is closed, letting you know you have messages that are waiting.



The Collaboration Chat button highlights to let you know you have a message.

Chapter 194

Remote Grading and Remote Monitor

This chapter describes how to set up Remote Grading using two separate DaVinci Resolve systems in different locations via the internet, to have one system remotely control the other for color grading. While DaVinci Remote Monitor allows you to stream a high quality video signal from one DaVinci Resolve system to another workstation over the internet or on the same network.

Introduction to Remote Grading

To enable colorists to work interactively with clients across the globe, DaVinci Resolve offers a remote grading option. It allows two matching DaVinci Resolve systems to be synchronized via an Internet connection such that changes made on the colorist's workstation are immediately applied on the remote client's workstation.

Cue commands are also synchronized to ensure that both systems are always on the same frame in the Timeline. Starting or stopping playback on the colorist's DaVinci Resolve also starts and stops the remote client system. While a remote grading session is in progress, input from the user at the remote client's DaVinci Resolve workstation is ignored.

Currently, the remote grading feature supports only color correction and does not allow editing or conforming during a session. The two colorist and remote DaVinci Resolve systems must have matching timelines and the number of clips, clip durations, and system resolutions must match. The requirements and limitations of a remote grading session are summarized below.

Requirements for Remote Grading

- The same version of DaVinci Resolve must be installed on both systems.
- The Timeline to be graded must be conformed on both machines prior to the start of the remote grading session.
- The number of clips on the Timeline and the duration of each clip must be identical.
- While grading, the active Timeline and versions on the remote client system are constantly updated. Creating, deleting, or switching the Timeline on the client's DaVinci Resolve is not allowed. Doing so will terminate the remote grading session immediately.
- You cannot make any grading adjustments on the remote client's DaVinci Resolve workstation until the remote grading session has ended.

NOTE: Remote grading does not require a shared project library.

Setting Up for Remote Grading

To start a remote grading session, the client's DaVinci Resolve must be able to connect to the colorist's system using TCP/IP.

1. Open DaVinci Resolve on the remote client's workstation (the one that's being remotely controlled), log in, and open the project that will be remotely graded.
2. Choose Workspace > Remote Grading (Ctrl-G) on the remote client's workstation. A window is displayed with text fields to enter the IP address and port number of the colorist's system.
3. Set the IP address field to the IP of the colorist's DaVinci Resolve workstation. If the colorist's system already has a public IP address, the port number can be left at its default value (15000). If the colorist's system is on a private network, the colorist or their network administrator should set the port number to one on the public IP router that is internally routed to port 15000 of the colorist's DaVinci Resolve.

4 Once the remote client clicks Connect, the client's DaVinci Resolve system will attempt to establish a connection with the remote colorist's workstation.

5 Once the connection is established, a pop-up appears on the colorist's screen asking for permission to accept a Remote Grading connection.

6 Click OK to accept, minimize the size of this dialog window, and continue grading normally.

The Remote Grading session will remain active until one of the users chooses to disconnect or an error occurs causing DaVinci Resolve to automatically terminate the session.

Remote Grading Restrictions

To allow operation over low bandwidth and a potentially long latency Internet connection there are some restrictions to remote operation.

- When playback is started, the playback speeds on the two DaVinci Resolve systems may differ. The frame positions are only guaranteed to be synchronized when playback is stopped.
- Input/output/display LUTs applied from the Config page on the colorist's DaVinci Resolve will not have any effect on the client system. LUTs selected on the client's DaVinci Resolve will be applied instead.
- Presets applied from the Config/Color pages on the colorist's system will not have any effect on the client's system. Presets selected on the client's DaVinci Resolve will be applied instead.

DaVinci Remote Monitor (Studio Version Only)

DaVinci Remote Monitor is an application that allows you to have access to a low latency, high quality video signal over a network for monitoring, editing, and color grading purposes. The DaVinci Remote Monitor shows the output of the host's Viewer in real time as they work in DaVinci Resolve. This allows producers to monitor a session, while editors and colorists have the ability to work remotely using the DaVinci Resolve interface and a data stream from a remote DaVinci Resolve workstation. This data stream is of high enough quality that you can run the signal through a Blackmagic DeckLink or UltraStudio device to a grading monitor and have the same confidence in the output as if it was connected locally.

The stream quality can be adjusted for your particular needs and available bandwidth. For example, an editor may only need an HD h.264 8-bit 4:2:0 codec for offline editing, while a colorist may need the full UHD h.265 12 bit 4:4:4 RGB codec for HDR grading.

NOTE: For clarity in this section we will refer to the main DaVinci Resolve workstation in the post house or data center that is streaming the video as the "Resolve Host" and the devices that are receiving the stream as the "Resolve Clients." However, in reality these are all just devices running the same version of the DaVinci Resolve Studio and the DaVinci Remote Monitoring apps.

Requirements for DaVinci Remote Monitor

In order to reliably stream a high-quality video signal from one system to another, there are some technical hardware and software limitations and requirements for the Host and Clients.

The Resolve Host must have the following hardware and software requirements for DaVinci Remote Monitor:

- The Resolve Host needs to have the Mac, Linux, or Windows version of DaVinci Resolve Studio installed.
- For Linux and Windows users, the Resolve Host needs an RTX series NVIDIA GPU and drivers installed. AMD and Intel GPUs are currently unsupported.
- The Host must have a Blackmagic Cloud account.

The Resolve Client must have the following hardware and software requirements for DaVinci Remote Monitor:

- The Resolve Client needs to have the Mac, Linux, or Windows version of DaVinci Resolve Studio installed. The DaVinci Remote Monitor App is automatically installed in the same folder as DaVinci Resolve.
- Apple iPhone and iPad devices are supported as Client platforms. Download the DaVinci Remote Monitor app from the App Store (The Studio Version of DaVinci Resolve is not required on these devices).
- For Linux and Windows users, the Resolve Client needs an RTX series NVIDIA GPU and drivers installed. AMD and Intel GPUs are currently unsupported.
- All Clients must have a Blackmagic Cloud account.

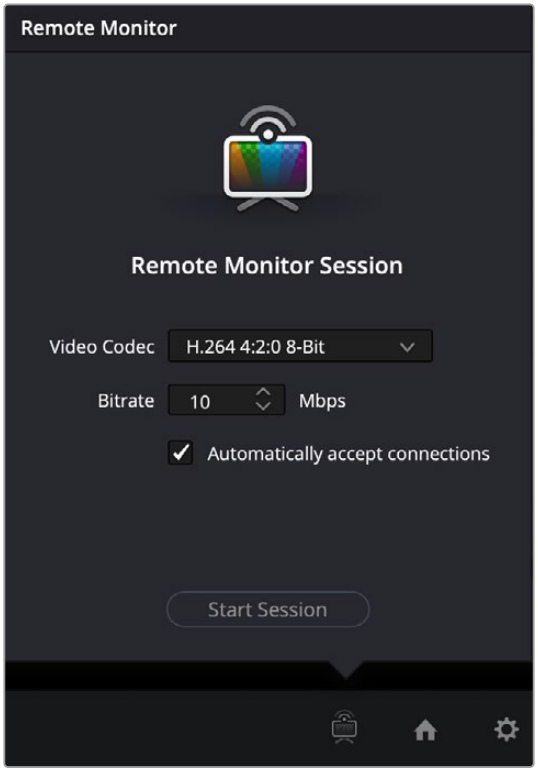
Setting Up DaVinci Remote Monitor

Setting up a Remote Monitor session is easily done from the DaVinci Resolve Studio interface: additionally, the Host and all Clients must have Blackmagic Cloud accounts.

To Start a DaVinci Remote Monitor session as the Resolve Host:

1. The Resolve Host needs to be running the full DaVinci Resolve Studio version of the software.
2. Select Workspace > Remote Monitor.
3. Sign into your Blackmagic Cloud account, if necessary.
4. In the Remote Monitor Window, select the Video Codec and Bitrate you wish to use for the session. Please note, the Video Codec used must be one that all the client devices support.

For maximum compatibility, H.264 4:2:0 8-bit is a good choice, however accurate color monitoring may necessitate using another 10- or 12-bit codec instead. Bandwidth needs to increase with the number of clients that are connected. While Remote Monitoring over the internet is possible, the best performance will be had with a wired ethernet connection.



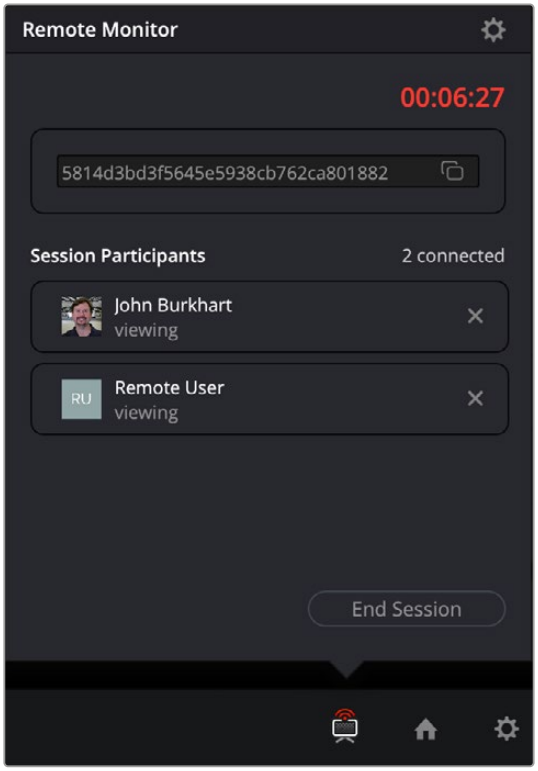
The DaVinci Remote Monitor Session Setup

5 Check the “Automatically accept connections” box to let anyone with the Session Code connect directly. If you wish to approve each connection manually, uncheck this box.

6 Click the Start Session button.

7 Copy the generated Session Code from its field, and disseminate it to all the Resolve Clients via email, text message, etc.

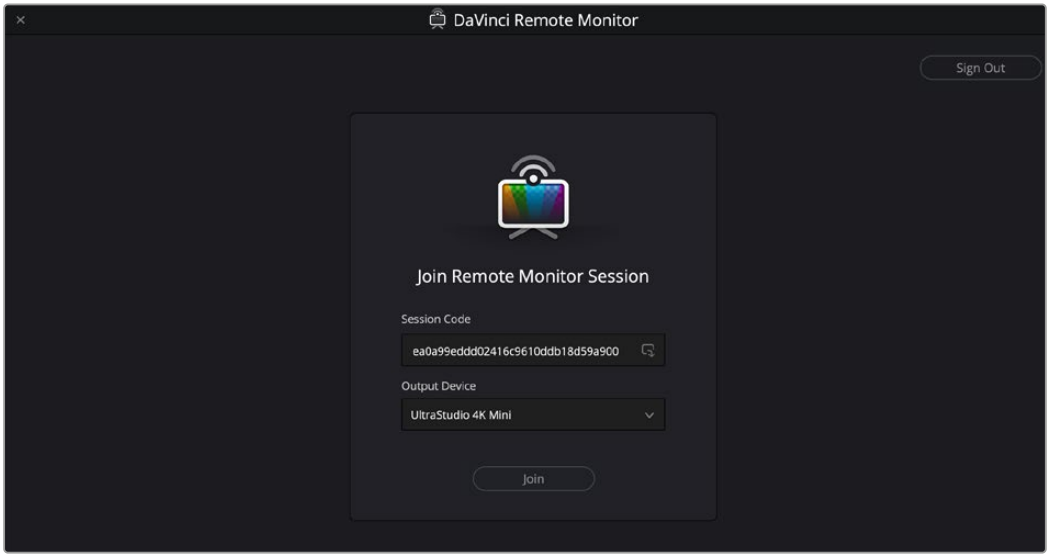
At this point your Remote Monitor has started, and a timer will show the duration of the current session. A Remote Monitor icon will appear in the lower right of the DaVinci Resolve interface, and the top of it will turn red to indicate that at least one Client has connected and you are now “live.” A Session Participants field shows you who is currently connected as a Client.



The DaVinci Remote Monitor showing the time connected and the participants involved

To Connect to a DaVinci Remote Monitor session as a Resolve Client:

1. The Resolve Client needs to have the full DaVinci Resolve Studio version of the software installed, or the iOS app installed.
2. Launch the DaVinci Remote Monitor app on your device. This is found in your DaVinci Resolve folder on your computer where you installed the software.
3. Sign into your Blackmagic Cloud account.
4. Paste the Session Code you received from the Resolve Host into the provided field.
5. Select the Output Device you wish to use for monitoring. This can be a connected computer display, or a Blackmagic Decklink or UltraStudio device for color accurate monitoring.
6. Click the Join button.



The DaVinci Remote Monitor app Join screen

At this point your Remote Monitor window will appear, and you will see and hear the output of the current viewer of the Resolve Host as they work.

NOTE: Remote Monitoring uses WebRTC to initiate connections between DaVinci Resolve Studio and multiple clients. However, some heavily restricted network setups may still block the initiation of a session, and a VPN may be required. A wired connection is recommended for the best performance.

To End a DaVinci Remote Monitor session as the Resolve Host:

1. Click on the DaVinci Remote Monitor icon in the lower right of the interface.
2. Click on the End Session button to stop the Remote Monitor for all users, or click on the X next to the name of a Client to disconnect the session for that user only.

To Leave a DaVinci Remote Monitor session as a Resolve Client:

1. Make the DaVinci Remote Monitor app active (not the Remote Monitor window).
2. Click on the Leave button to end your session.

To Change the Codec and Bitrate of a current DaVinci Remote Monitor session as the Resolve Host:

1. Click on the DaVinci Remote Monitor icon in the lower right of the interface.
2. Click on the Settings icon in the upper right of the Remote Monitor window.
3. Select a new Codec and Bitrate for the video stream.
4. Click on the Save button.

This will change the streaming settings to the new codec and bitrate that you chose. Existing Clients will be automatically reconnected to the new stream without having to do anything on their end. This lets you easily change the quality of the video stream on the fly to compensate for bandwidth and hardware issues.

DaVinci Remote Monitoring Using IP Address Connections

As an option, you can use Remote Monitoring over normal IP Address Connections, rather than having to sign in through Blackmagic Cloud. However, you will need some technical knowledge on setting up your network appropriately.

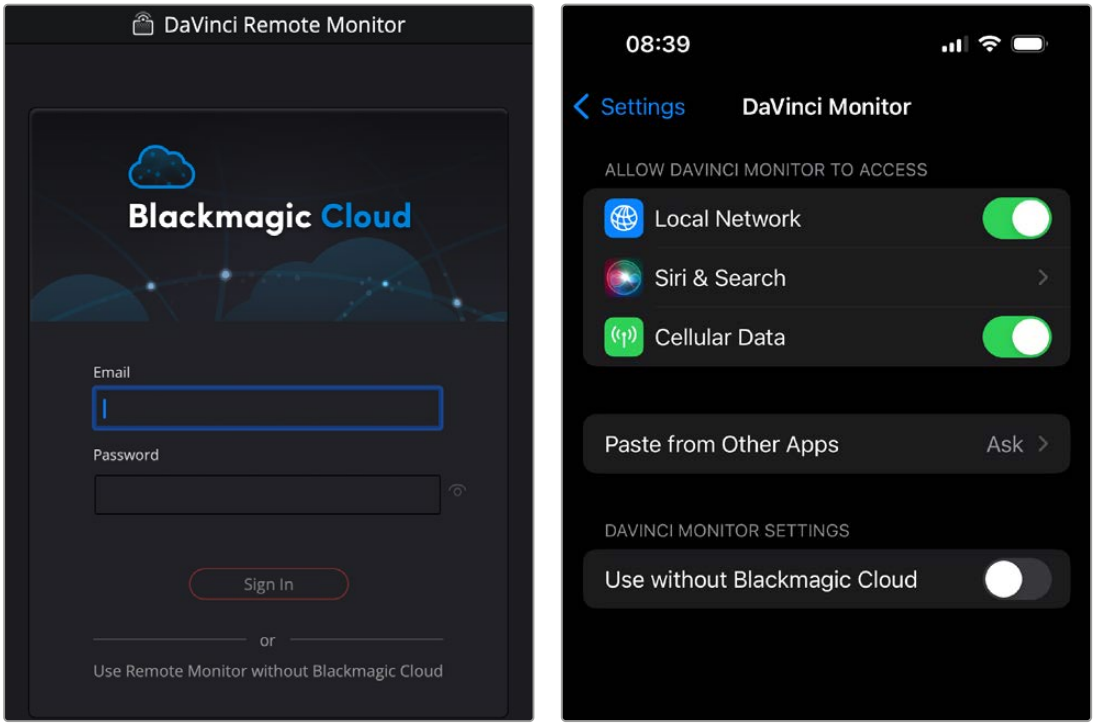
Setting up Remote Monitoring over IP connections on the Resolve Host

Follow the instructions below to set up your host grading computer for other people to monitor.

1. Make sure you are signed out of Blackmagic Cloud in Preferences > Internet Accounts.
2. In Preferences > System > General, check the “Use Remote Monitoring without Blackmagic Cloud” box.
3. Select Workspace > Remote Monitoring.
4. Adjust the codec and bit-rate parameters you want, then click Start Session.
5. Share the IP Address or configured host name for the Resolve host with the clients.

Setting up Remote Monitoring over IP connections on the Resolve Clients

Follow the instructions below to set up your client computer to monitor the host’s workstation.



The Use Remote Monitor without Blackmagic Cloud settings in the computer and iOS versions

1. Launch the DaVinci Remote Monitor application.
2. In the Remote Monitor setup dialog, choose “Use Remote Monitor without Blackmagic Cloud.”
3. In the iOS or iPadOS versions of the App, go to the iOS Settings > DaVinci Monitor, and toggle on “Use Remote Monitor without Blackmagic Cloud.”
4. Enter the Resolve host’s server IP Address or Host Name in the Host field.
5. Click Join.

Firewall exceptions and appropriate port forwarding will need to be manually configured in order to use this mode. The procedure to initiate a session and accept connections remains the same. This mode uses TCP server port 16410 and TCP/UDP port 16411, 16412, etc. for each client.

DaVinci Remote Monitoring via User Specified TURN Servers

When collaborating across complex network security setups that restrict the WebRTC STUN protocol, you may now decide to use self-configured or cloud-based TURN servers to route and relay monitoring streams.

To use this function, check the box under Preferences > System > General > Use TURN server for Remote Monitoring. Then add the URL of your custom TURN server.

DaVinci Remote Monitor Restrictions

There are currently some limitations to the DaVinci Remote Monitor application to be aware of.

- When connecting over the internet, bandwidth restrictions can hamper performance. If the bandwidth drops too low or cuts out completely, the Host will disconnect with an error message.
- Currently DaVinci Remote Monitor only works in the Media, Cut, Edit, Color, and Deliver pages.
- Currently Audio is limited to only 2 channels.
- Currently on the Color page, GUI viewer overlays (for power windows, reference wipes, Open FX controls, etc.) do not display in the DaVinci Remote Monitor application.

Codec Plugins (Studio Version Only) 4007
MainConcept 4007

DaVinci Resolve Renderer Plugin for OFX VFX Applications (Studio Version Only)

The Open FX plugin DaVinci Resolve Renderer allows third-party applications to open and apply DaVinci Resolve's color changes using exported DRX stills. Essentially this turns an installation of DaVinci Resolve Studio into one large OFX plugin. This can be very useful when round tripping with various VFX authoring applications where you may want to maintain the exact look created in DaVinci Resolve.

Exporting a DRX still contains much more information about the grade than a simple LUT. DRX files can include data like all the native color and sizing palettes and other items you stored in a Gallery still. This ensures that the grade the colorist created can be exactly replicated in the VFX software.

As of this writing, the following attributes WILL transfer via the DaVinci Resolve OFX Renderer Plugin:

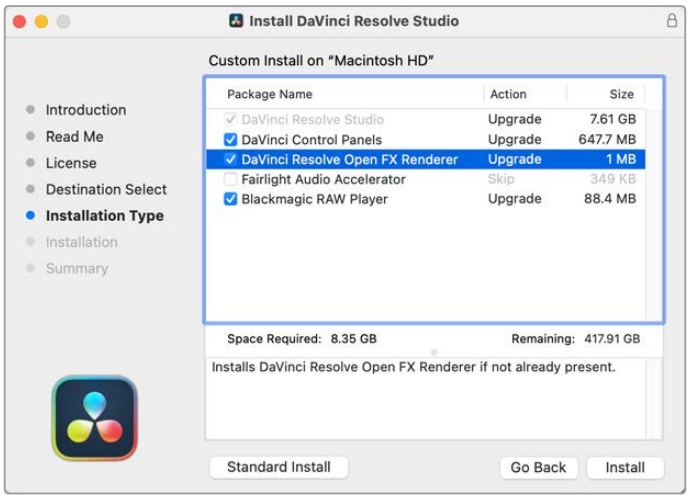
- All native color palettes (Primaries, HDR, Curves etc.).
- All native sizing palettes (Input, Output, Node etc.).
- Most Resolve FX.
- Most third-party Open FX.

As of this writing, the following attributes WILL NOT transfer via the DaVinci Resolve OFX Renderer Plugin:

- Resolve and Open FX that are temporal based.
- Magic Mask.

To set up the DaVinci Resolve OFX Renderer Plugin:

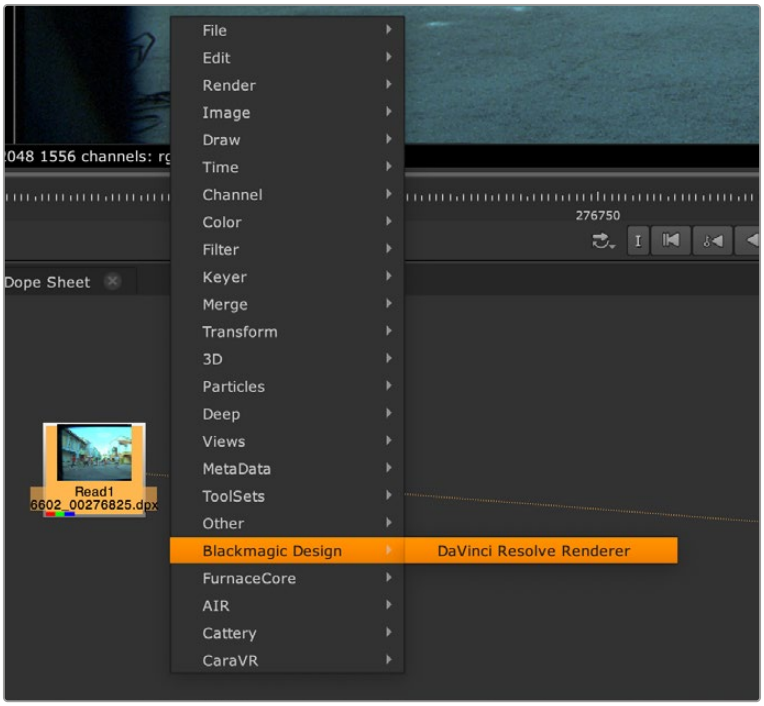
1 When installing DaVinci Resolve Studio, select Custom Install and then check the plugin option in the program installer.



Select Custom Install, then check DaVinci Resolve Open FX Renderer to install the plugin

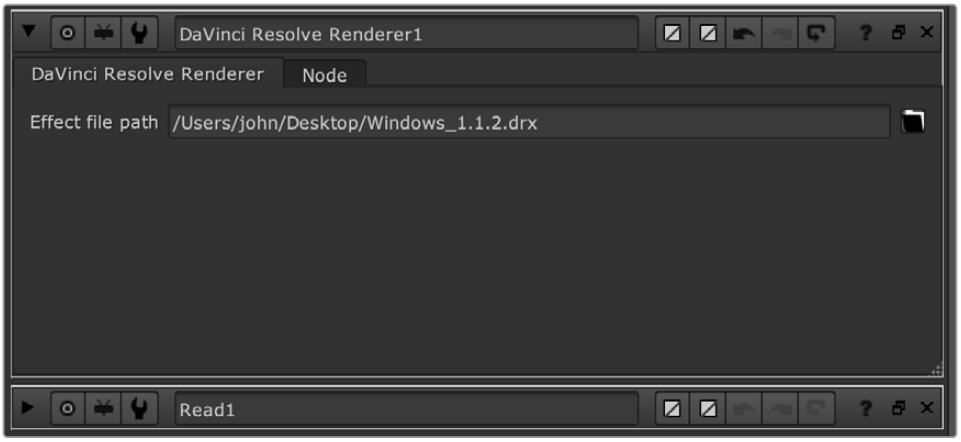
2 Create your grade for a clip in the Color page, then save a still to the Gallery. From the Gallery, export a .DRX file.

3 In the third-party application, apply the DaVinci Resolve Renderer plugin where appropriate for your composition.



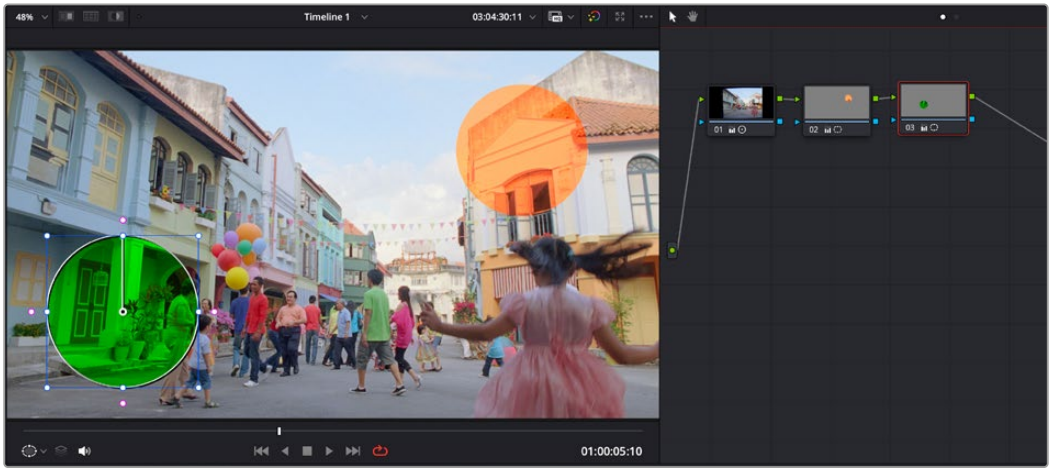
Inserting the DaVinci Resolve Renderer OFX into a Nuke node tree

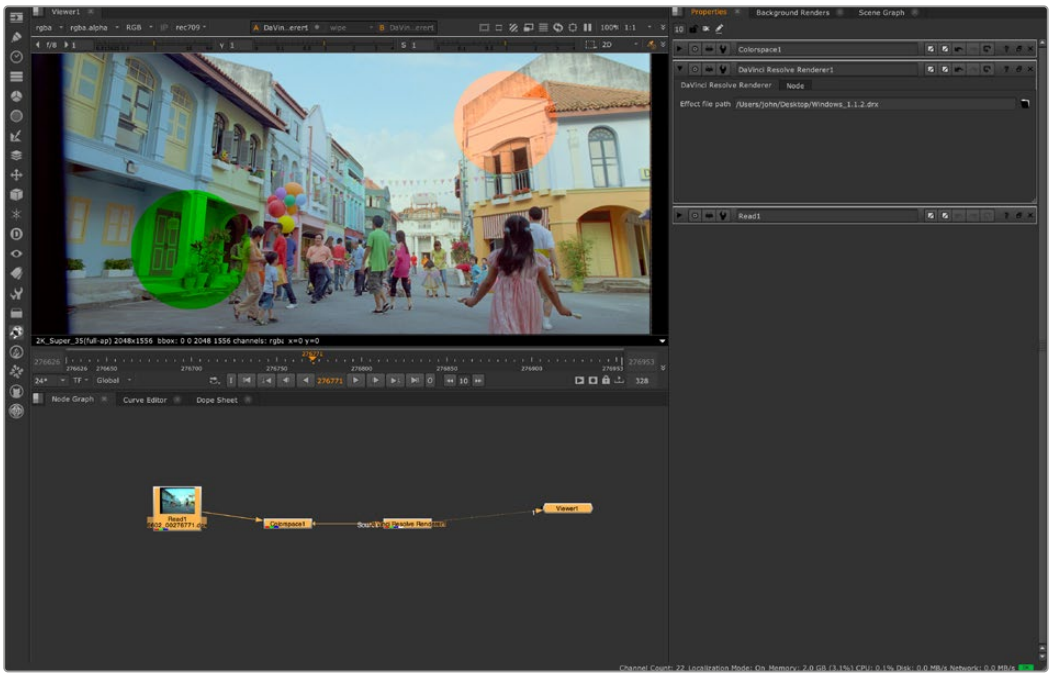
4 In the DaVinci Resolve Renderer plugin in your application, choose the .DRX file you exported from the file browser.



Select the .DRX file you exported from DaVinci Resolve in the plugin.

The Color Grade Plugin should work with most Open FX-capable VFX software, such as Autodesk Flame and The Foundry's Nuke.





The DaVinci Resolve Renderer OFX Plugin in Nuke (below), showing a balanced grade with green and orange Power Windows from multiple nodes in DaVinci Resolve (above).

IMPORTANT: Use of the plugin requires a DaVinci Resolve Studio license on the system that is running the third party application.

Workflow Integrations in DaVinci Resolve (Studio Version Only)

DaVinci Resolve allows third parties to create their own custom interface plugins using scripting languages. This makes possible a direct integration between DaVinci Resolve and other software programs, for a variety of uses. More than one Integration plugin can be active at the same time.

After installation, plugins can be enabled in DaVinci Resolve by going to Workspace > Workflow Integrations, and selecting your plugin from the dropdown menu.

Creating Workflow Integration Plugins

Users can write their own Workflow Integration Plugin (an Electron app), using Resolve Javascript's API, and Python or Lua scripts. For more information on how to create a Workflow Integration Plugin go to Help > Documentation > Developer, and open up the Workflow Integrations folder for technical details and sample code.

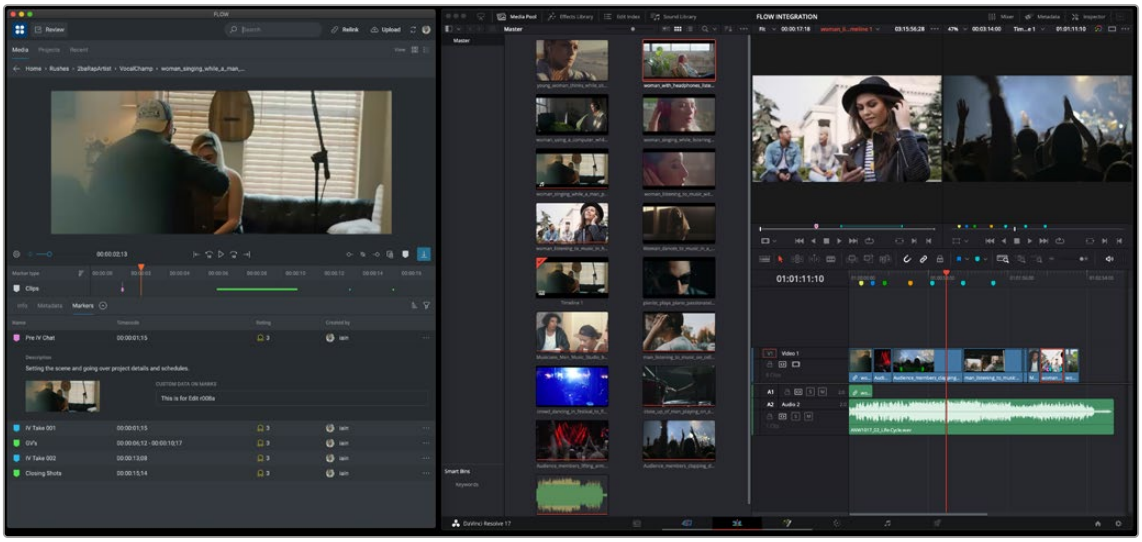
Workflow Integration Plugins

There are several Media Asset Management (MAM) systems that can now directly be accessed through DaVinci Resolve using the Workflow Integration Plugins.

EditShare

EditShare has created a workflow integration plugin that allows DaVinci Resolve to interface directly with their FLOW media management system. This plugin allows you to comment, search, and preview media in FLOW without leaving DaVinci Resolve. You can also upload revisions, manage proxy media, and maintain full metadata support throughout the process.

For more information on this plugin and how FLOW works with DaVinci Resolve go to:
https://editshare.com/say-hello-to-flow-and-davinci-resolve-studio/

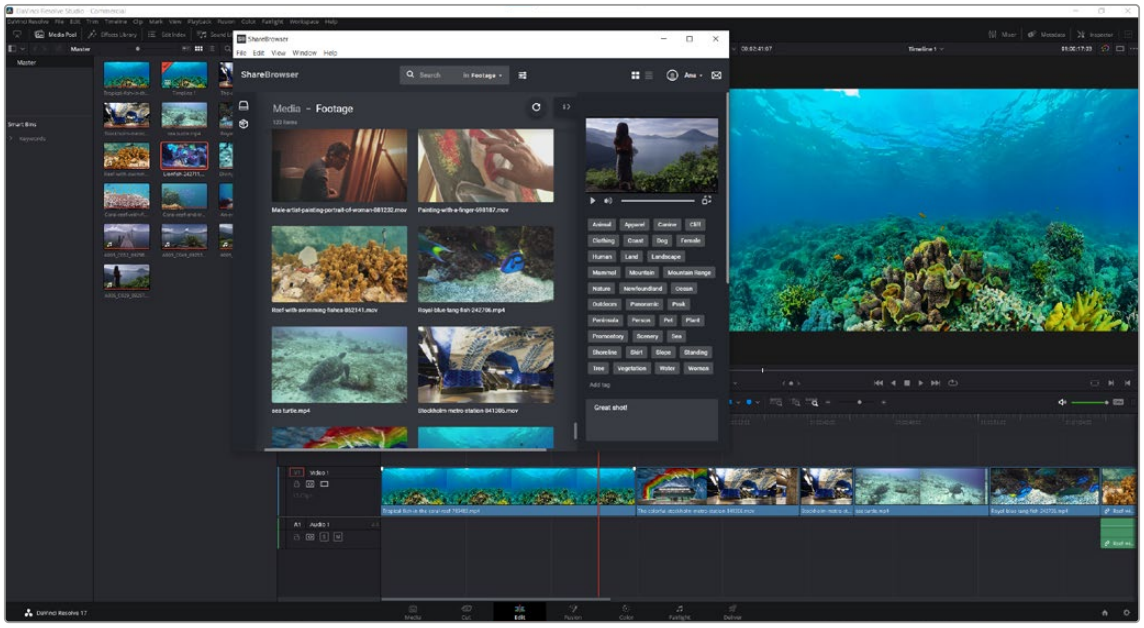


EditShare's FLOW Integration Plugin

Studio Network Solutions (SNS)

Studio Network Solutions (SNS) created the ShareBrowser Integration Plugin to interface between DaVinci Resolve and their ShareBrowser media asset management software, included with SNS EVO media servers. This plugin allows your team to search, tag, preview, comment, organize, and import media without leaving the DaVinci Resolve interface. Your team can directly import the media into a DaVinci Resolve project and the metadata you entered carries over along with the media.

For more information on this plugin and how SNS's high-speed server or cloud solutions work with DaVinci Resolve, go to: https://www.studionetworksolutions.com/.



SNS ShareBrowser Integration Plugin

Codec Plugins (Studio Version Only)

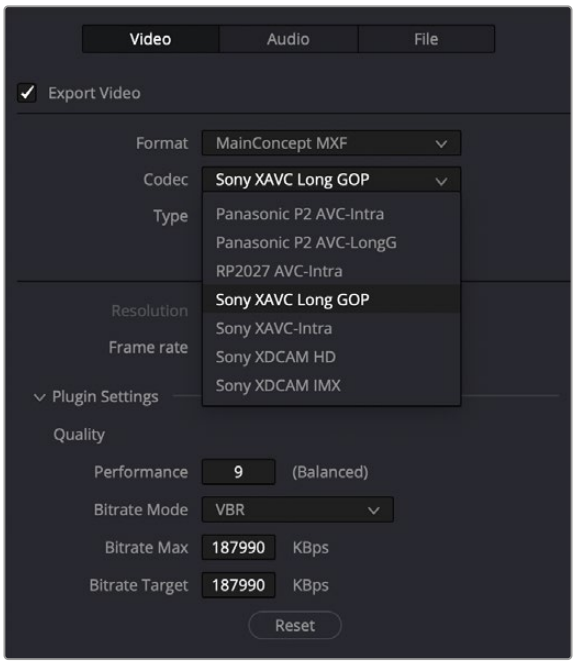
Codec plugins allow third parties to install new codecs for encoding in the Deliver page that are not currently supported in the main DaVinci Resolve software. This opens the door for extremely specific deliverables that would normally require passes through multiple programs to deliver.

MainConcept

The MainConcept Codec Plugin allows you to render your DaVinci Resolve Studio timelines in a variety of new codecs:

- AS-11 UK SD, AS-11 UK HD along with an included XML metadata file to create AS-11 UK DPP compliant content.
- MainConcept's software HEVC Main and Main 10 profiles, allowing H.265 files in 8-bit/10-bit 4:2:0/4:2:2 at up to 8K resolution.
- MainConcept MXF and MP4, allowing encoding into the native camera formats used by Sony XAVC/XDCAM and Panasonic P2 AVC based cameras.

More information on the MainConcept Codec Plugin for DaVinci Resolve can be found here: https://www.mainconcept.com/blackmagic-plugins



The MainConcept Codec Plugin for DaVinci Resolve options in the Deliver page

Chapter 196

Creating DCTL LUTs

This chapter describes how to create DCTL LUTs to perform your own custom mathematical transformations in DaVinci Resolve.

Contents

About DCTL 4009
DCTL Syntax 4009
A Simple DCT LUT Example 4011
A Matrix DCT LUT Example 4011
A More Complex DCT LUT Example 4012

About DCTL

DCTL files are actually color transformation scripts that DaVinci Resolve sees and applies just like any other LUT. Unlike other LUTs, which are 1D or 3D lookup tables of values that approximate image transformations using interpolation, DCTL files are actually comprised of computer code that directly transforms images using combinations of math functions that you devise. Additionally, DCTL files run natively on the GPU of your workstation, so they can be fast.

Anyone with the mathematical know-how can make and install a DCTL. Simply enter your transformation code, using a syntax that's similar to C (described in more detail below), into any text editor capable of saving a plain ASCII text file, and make sure its name ends with the ".dctl" (DaVinci Color Transform Language) file extension. Once that's done, move the file to the LUT directory of your workstation. Where that is depends on which OS you're using:

- **On Mac OS X:** Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
- **On Windows:** C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
- **On Linux:** /home/resolve/LUT

When DaVinci Resolve starts up, assuming the syntax of your .dctl is correct, they appear in the Color page Node contextual menu within the DaVinci CTL submenu.

DCTL Syntax

Users need to put __DEVICE__ in front of each function they write. For example:

```
__DEVICE__ float2 DoSomething()
```

The main entry function (transform) should come after all other functions, with the following format argument:

```
__DEVICE__ float3 transform(float p_R, float p_G, float p_B)
```

The main entry function must also have a float3 return value.

For the following floating point math functions, please use the described syntax:

```
float _fabs(float)                    // Absolute Value
float _powf(float x, float y          // Compute x to the power of y
float _logf(float)                    // Natural logarithm
float _log2f(float)                   // Base 2 logarithm
float _log10f(float)                  // Base 10 logarithm
float _exp2f(float)                   // Exponential base 2
float _expf(float)                    // Exponential base E
float _copysignf(float x, float y)    // Return x with sign changed to sign y
float _fmaxf(float x, float y)        // Return y if x < y
float _fminf(float x, float y)        // Return y if x > y
float _saturatef(float x, float       // Return min(max(x, minVal), maxVal)
minVal, float maxVal)
float _sqrtf(float)                   // Square root
int   _ceil(float                     // Round to integer toward + infinity
```

```
int   _floor(float)                  // Round to integer toward - infinity
float _fmod(float x, float y)        // Modulus. Returns x – y * trunc(x / y)
float _fremainder(float x, float y)  // Floating point remainder
int   _round(float x)                // Integral value nearest to x rounding
float _hypotf(float x, float y)      // Square root of (x^2 + y^2)
float _atan2f(float x)               // Arc tangent of (y / x)
float _sinf(float x)                 // Sine
float _cosf(float x)                 // Cosine
float _acosf(float x)                // Arc cosine
float _asinf(float x)                // Arc sine
float _fdivide(float x, float y)     // Return (x / y)
float _frecip(float x)               // Return (1 / x)
```

The following functions support integer type:

```
min, max, abs, rotate
```

Other supported C Math functions include:

```
acosh, acospi, asinh, asinpi, atan, atanh, atanpi, atan2pi, cbrt, cosh, cospi,
exp10, expm1, trunc, fdim, fma, lgamma, log1p, logb, rint, round, rsqrt,
sincos, sinh, sinpi, tan, tanh, tanpi, tgamma
```

Vector types float2, float3, and float4 are supported. The data fields are:

```
float x
float y
float z
float w
```

To generate a vector value, use make_floatN() where N = 2, 3, or 4.

Users can define their own structure using “typedef struct.” For example:

```
typedef struct
    {
        float c00, c01, c02;
        float c10, c11, c12;
    } Matrix;
```

To declare constant memory, use *__CONSTANT__*. For example:

```
__CONSTANT__ float NORM[] = {1.0f / 3.0f, 1.0f / 3.0f, 1.0f / 3.0f};
```

To pass the constant memory as a function argument, use the *__CONSTANTREF__* qualifier, e.g.:

```
__DEVICE__ float DoSomething(__CONSTANTREF__ float* p_Params)
```

A float value must have the ‘f’ character at the end (e.g. 1.2f).

A Simple DCT LUT Example

The following code shows an example of how to create a simple color gain transformation using the DCT LUT syntax.

```
// Example to demonstrate simple color gain transformation
__DEVICE__ float3 transform(float p_R, float p_G, float p_B)
{
    const float r = p_R * 1.2f;
    const float g = p_G * 1.1f;
    const float b = p_B * 1.2f;
    return make_float3(r, g, b);
}
```

A Matrix DCT LUT Example

The following code shows an example of creating a matrix transform using the DCT LUT syntax.

// Example to demonstrate the usage of user defined matrix type to transform RGB to YUV in Rec. 709

```
__CONSTANT__ float RGBToYUVMat[9] = { 0.2126f ,  0.7152f , 0.0722f,
                                     -0.09991f, -0.33609f, 0.436f,
                                      0.615f   , -0.55861f, -0.05639f };

__DEVICE__ float3 transform(int p_Width, int p_Height, int p_X, int p_Y,
float p_R, float p_G, float p_B)
{
    float3 result;

    result.x = RGBToYUVMat[0] * p_R + RGBToYUVMat[1] * p_G + RGBToYUVMat[2] *
p_B;
    result.y = RGBToYUVMat[3] * p_R + RGBToYUVMat[4] * p_G + RGBToYUVMat[5] *
p_B;
    result.z = RGBToYUVMat[6] * p_R + RGBToYUVMat[7] * p_G + RGBToYUVMat[8] *
p_B;

    return result;
}
```

A More Complex DCT LUT Example

The following code shows an example of creating a mirror effect, illustrating how you can access pixels spatially.

```
// Example of spatial access for mirror effect

__DEVICE__ float3 transform(int p_Width, int p_Height, int p_X, int p_Y, __
TEXTURE__ p_TexR, __TEXTURE__ p_TexG, __TEXTURE__ p_TexB)
{
    const bool isMirror = (p_X < (p_Width / 2));
    const float r = (isMirror) ? _tex2D(p_TexR, p_X, p_Y) : _tex2D(p_TexR, p_
Width - 1 - p_X, p_Y);
    const float g = (isMirror) ? _tex2D(p_TexG, p_X, p_Y) : _tex2D(p_TexG, p_
Width - 1 - p_X, p_Y);
    const float b = (isMirror) ? _tex2D(p_TexB, p_X, p_Y) : _tex2D(p_TexB, p_
Width - 1 - p_X, p_Y);
    return make_float3(r, g, b);
}
```

Chapter 197

TCP Protocol for DaVinci Resolve Transport Control

This chapter describes how to create third-party utilities that use Transport Control with DaVinci Resolve.

Contents

About the TCP Protocol Version 1.2 4014
Data Types 4014
Command Format 4014
Response Format 4014
Communication Delays 4014
Status Response Values 4015
TCP Protocol Stream 4015
connect 4015

play 4015
gettc 4015
getframerate 4015

About the TCP Protocol Version 1.2

This protocol defines the communication standard between third-party applications (“Client”) and DaVinci Resolve (“Server”) using the TCP protocol.

Port number 9060 will be used by the server. SSL will not be used in this protocol. Communication takes the form of request-response messages, where the Client initiates a command, and the Server responds appropriately.

To use this protocol, you must first type the following string into the Advanced panel of the DaVinci Resolve System Preferences:

```
System.Remote.Control = 1
```

Data Types

The following data types are used in this protocol:

- **float (f):** A 4-byte IEEE 754 single precision float
- **int (i):** A 4-bytes signed int
- **unsigned char (uc):** A 1-byte unsigned char (0–255)
- **string (s):** A UTF-8 encoded string. No terminator is specified. The string is a composite type, transmitted as a single int (i) specifying the number of characters in the string (N), followed by N unsigned chars (uc) containing the letters of the string.

NOTE: The bytes of the float and int types are transmitted in little endian order.

Command Format

Commands are transmitted as a single string (using characters a–z (0x61 – 0x7A) only), followed by any additional payload required by the command in the definition.

Response Format

The response to any command is composed of a status byte (unsigned char), followed by any additional payload required by the response.

Communication Delays

Once the first byte of the command string is sent, the rest of the command string and the payload data must follow without delay. At the end of COMMAND, the server must respond immediately. If there is a delay of more than 5 seconds during this process, the party waiting for data may drop the connection assuming that the peer has become unresponsive.

There is currently no limit on the delay between two consecutive commands.

NOTE: Alternatively, a maximum allowable delay may be defined, in which case, the client may issue periodic ‘connect’ commands to keep the connection alive.

Status Response Values

The meaning of the status values are as follows:

- **0x00:** Command was executed successfully. Any additional payload is sent as expected.
- **0xFF:** Command could not be executed successfully. No additional payload will follow.

TCP Protocol Stream

The following commands can be sent over the protocol stream.

connect

The client initiates the stream by sending a connect command string. There is no payload. The server responds with a status value of 0x00.

goto

The client sends a goto command string followed by four unsigned chars representing the hour, minute, second, and frame of the timecode.

The server responds with an appropriate status byte based on the execution of the command.

play

The client sends a play command string followed by a floating point value. Play in real-time is 1.0, stop is 0.0, reverse is -1.0, 2x is 2.0, etc.

The server responds with an appropriate status byte based on the execution of the command.

gettc

The client sends a gettc command string.

The server responds with an appropriate status byte (status byte may be 0xFF if no timeline exists, for instance). If the status byte is 0x00, it is followed by four unsigned chars representing the hour, minute, second, and frame of the timecode.

getframerate

The client sends a getframerate command string.

The server responds with an appropriate status byte. If the status byte is 0x00, it is followed by a floating point value for the frame rate.

Menu Description

DaVinci Resolve Menu

For ease of use navigating this manual, each menu item is listed here, and by clicking on the name of the menu function, you will be taken to the appropriate part of the manual that describes that function.

DaVinci Resolve

About DaVinci Resolve
Opens the splash screen showing the installed version of DaVinci Resolve.

Preferences – Page 96
Opens the System and User Preferences window.

Keyboard Customization – Page 121
Opens the Keyboard Customization Window.

Check for Updates
Checks to see if a newer version of DaVinci Resolve is available.

Quit DaVinci Resolve
Exits the program.

File

New Project – Page 76
Creates a new project.

Open Recent Project – Page 87
Open a recent project from a list.

New Bin – Page 506
Creates a new Bin.

New Smart Bin – Page 366
Creates a new Smart Bin.

New Timeline – Page 621
Creates a new timeline.

Close Current Timeline
Closes the active timeline.

Close Project – Page 92
Closes the active project.

Save Project – Page 87
Saves the current project.

Save Project As – Page 87
Rename and create a copy of the current project before you save it.

Revert to Last Save Version – Page 75
Opens the last saved version of the current project, discarding any changes made after that.

Import
Tools for the importation of files and media into DaVinci Resolve.

- **Bin** – Page 380
- **Media** – Page 380
- **Media from XML** – Page 366
- **Timeline** – Page 381
- **Fusion Composition** – Page 1199
- **Subtitles** – Page 1008
- **Pre-conformed EDL** – Page 1117
- **Batch List From EDL** – Page 437

Import Project – Page 76
Imports a DaVinci Resolve Project file (.drp).

Import Metadata To – Page 412
Imports Metadata from a .csv file into DaVinci Resolve.

Export
Tools for the exportation of files and media from DaVinci Resolve.

- **Bin** – Page 380
- **Timeline** – Page 381
- **Subtitles** – Page 1008
- **Fusion Composition** – Page 1199
- **Current Frame as Still** – Page 353

Export Project – Page 75
Exports a DaVinci Resolve Project File (.drp).

Export Metadata From – Page 411
Exports Metadata from DaVinci Resolve to a .csv file.

Quick Export – Page 610
Opens the Quick Export Window.

Project Manager – Page 75
Opens the Project Manager Window.

Project Settings – Page 135
Opens the Project Settings Window.

Project Notes – Page 92
Opens the Project Notes editor.

Single User Project – Page 3957
Disables the Project Collaboration features.

Multiple User Collaboration – Page 3978
Enables Project Collaboration with other DaVinci Resolve workstations

Media Management – Page 921
Opens the Media Management Window.

Reconform from Bins – Page 1078
Reconforms a timeline using media in a selected bin.

Reconform from Media Storage – Page 1081
Reconforms a timeline using media in a specific file system folder.

easyDCP – Page 3898
Exposes the easyDCP toolset.

Dolby Vision® – Page 254
Loads the license and configuration files to enable Dolby Vision advanced trim controls

Blackmagic Cloud Account – Page 3939
Log in and switch Blackmagic Cloud accounts.

Edit

Undo – Page 71
Undos the previous change.

Redo – Page 71
Redo the previous change.

History – Page 71
Opens the Undo History submenu.

Cut – Page 758
Performs a cut operation on the current selection.

Ripple Cut – Page 758
Performs a ripple cut operation on the current selection.

Cut Head – Page 3638
Cuts the clip from the playhead backwards in the Fairlight page.

Cut Tail – Page 3638
Cuts the clip from the playhead forwards in the Fairlight page.

Copy – Page 758
Performs a copy operation on the current selection.

Copy Head – Page 3638
Copies the clip from the playhead backwards in the Fairlight page.

Copy Tail – Page 3638
Copies the clip from the playhead forwards in the Fairlight page.

Paste – Page 758
Pastes the previously copied/cut selection.

Paste Insert – Page 758
Pastes a clip as an insert edit.

Paste Attributes – Page 940
Pastes video and audio attributes.

Paste Value – Page 3133
Pastes a the value of a specific parameter between Color nodes.

Remove Attributes – Page 941
Removes audio and video attributes.

Dolby Vision® – Page 254
Copy and Paste Trim metadata for Dolby Vision.

Duplicate Clip or Current Timeline – Page 388
Makes a copy of the current clip or timeline.

Duplicate Selection – Page 3634
Duplicates one or more selected clips in Fairlight.

Delete Selected
Performs a delete function on all selected items.

Ripple Delete – Page 717
Performs a ripple delete on the selected clip.

Delete Gaps – Page 718
Deletes gaps in the active timeline.

Select All
Performs a Select All function on the active panel.

Deselect All
Clears any selections in the active panel.

Select – Page 696
Opens up a submenu for selecting adjacent clips in a timeline.

Insert – Page 783
Performs an Insert Edit using the selected clip.

Overwrite – Page 782
Performs an Overwrite Edit using the selected clip.

Replace – Page 784
Performs a Replace Edit using the selected clip.

Place on Top – Page 542
Performs a Place on Top Edit using the selected clip.

Ripple Overwrite – Page 541
Performs a Ripple Overwrite Edit using the selected clip.

Fit to Fill – Page 768
Performs a Fit to Fill Edit using the selected clip.

Append to End of Timeline – Page 792
Adds the selected clip to the end of the timeline.

Multicam – Page 835
Exposes the Multicam editing controls.

Swap Clips Towards Left – Page 753
Swaps the selected clips with the clip to the left of the selection.

Swap Clips Towards Right – Page 753
Swaps the selected clips with the clip to the right of the selection.

Switch to Timeline After Edit
Automatically switches focus to the timeline after an edit, rather than the Source Viewer.

Decompose Compound Clips on Edit – Page 853
Automatically decomposes nested clips on timelines for easier editing.

Trim

Normal Edit Mode – Page 748
Puts the timeline in Selection Mode.

Trim Mode – Page 857
Puts the timeline in Trim Mode.

Range Selection Mode – Page 3612
Selects Range Mode in Fairlight.

Dynamic Trim mode – Page 887
Puts the timeline in Dynamic Trim Mode.

Toggle Slip/Slide Mode – Page 887
Toggles between slip and slide trim modes.

Blade Edit Mode – Page 755
Switches the timeline to blade mode.

Trim Editor – Page 863
Enables the Precision Trim Editor.

Select Nearest Edit Point
Selects the nearest edit point to the playhead

Select Nearest Video Edit Point
Selects the nearest edit point to the playhead on the video tracks only.

Select Nearest Audio Edit Point
Selects the nearest edit point to the playhead on the audio tracks only.

Select Nearest Clip/Gap
Selects the nearest clip or gap to the playhead.

Select All Clips Under Playhead
Selects all clips on all tracks under the playhead.

Edit Point Type
Toggles the currently selected edit point among the outgoing, centered, or incoming part of the edit

Toggle V+A/V/A
Toggles the Edit Point type above between video, audio, or video and audio combined selections.

Select Nearest Edit To – Page 868
Selects the nearest edit point to a variety of clip parameters.

Select Nearest Clip To – Page 868
Selects the nearest clip to a variety of clip parameters.

Nudge
Opens a menu to move the selected clips one frame, or multiple frames left or right.

Trim Start – Page 885
Cuts all clips intersecting the playhead from that point backwards.

Trim End – Page 885
Cuts all clips intersecting the playhead from that point forwards.

Trim to Selection – Page 3507
Trims the heads and tails of the clips to the selected range in the Fairlight page.

Extend Edit – Page 887
Resizes one or more selected edit points or clips.

Extend Edit Selection To – Page 887
Opens a menu to select previous and next tracks and edits for the Extend Edit function.

Move Edit Selection To – Page 887
Opens a menu to move to previous and next tracks and edits for the Extend Edit function.

Resize – Page 857
Changes the clip in/out points based on the playhead position.

Ripple – Page 857
Changes the clip in/out points based on the playhead position, using a Ripple operation.

Roll – Page 857
Changes the clip in/out points based on the playhead position, using a Roll operation.

Slip Playhead To – Page 887
Slips the clip from the current position of the playhead to the in or out point of the clip.

Fade In to Playhead – Page 984
Creates a fade in from the beginning of the clip to the playhead position.

Fade Out to Playhead – Page 984
Creates a fade out from the playhead position to the end of the clip.

Crossfade Selection
Creates a crossfade for the selected range in the Fairlight page.

Slip Audio – Page 724
Opens a menu to slip audio forwards and backwards at a frame or subframe level.

Slip Eye – Page 326
Slips the opposite eye left or right one frame in the Color Page's Stereo 3D palette.

Timeline

Add Transition – Page 945
Adds the default transition to the selected edit point.

Add Video Only Transition – Page 945
Adds the default transition to the selected Video edit point only.

Add Audio Only Transition – Page 945
Adds the default transition to the selected Audio edit point only.

Bounce Selected Tracks to New Layer – Page 3717
Bounces the selected tracks to a new layer in the Fairlight page.

Bounce Mix to Track – Page 3717
Bounces the selected mix to a new track in the Fairlight page.

Select Clips Backward – Page 707
Selects all clips backward from the playhead on either a single track, or all tracks.

Select Clips Forward – Page 707
Selects all clips forward from the playhead on either a single track, or all tracks.

Select Clips With Flag Color – Page 708
Selects all clips previously flagged with a specific color.

Select Clips With Marker Color – Page 708
Selects all clips having markers with a specific color.

Select Clips With Clip Color – Page 708
Selects all clips with a specific color.

Razor – Page 755
Activates the Razor (Blade) tool.

Split Clip – Page 747
Splits a clip at the playhead position.

Join Clip – Page 747
Joins two clips that are separated by a through edit.

Detect Scene Cuts – Page 451
Activates Scene Cut Detection on the current selection.

Create Subtitles from Audio – Page 1014
Automatically creates subtitles based off speech in audio tracks.

Mute Tracks – Page 3714
Mutes the selected audio track in the Fairlight Page.

Clear Mutes – Page 3714
Un-mutes all the tracks in the Fairlight Page

Solo Tracks – Page 3714
Solos the selected audio track in the Fairlight Page.

Clear Solo – Page 3714
Un-solos all tracks in the Fairlight Page.

Clean Up Video Tracks – Page 766
Opens a toolset to improve the organization of a timeline's video tracks.

Flatten Audio Track Layers – Page 3800
Flattens out Track Layers in the Fairlight Page.

Trim Audio Edits to Frame Boundaries – Page 115
Eliminates any sub-frame audio adjustments.

Switch to Camera Originals – Page 512
Toggles between Camera Masters and ISO's in ATEM projects.

Match Frame – Page 830
Performs a Match Frame operation on the clip.

Swap Timeline and Source Viewer – Page 853
Opens a timeline loaded in the source viewer in a timeline instead.

Snapping
Turns playhead snapping on and off.

Linked Selection – Page 720
Toggles linked selection of clips.

Linked Move Across Tracks – Page 721
Toggles linked clips moving tracks together.

Selection Follows Playhead – Page 644
Toggles the automatic selection of the clip under the playhead.

Layered Audio Editing – Page 3641
Turns on Audio Layering in the Fairlight Page.

Audio Scrubbing – Page 645
Toggles audio scrubbing on or off.

Loop Jog – Page 3584
Toggles Loop Jog in the Fairlight Page.

Ripple Timeline Markers – Page 816
Timeline markers will reflow with ripple operations.

Playback Post-Roll – Page 645
The playhead will continue playing past the last clip in the timeline.

Track Destination Selection – Page 769
Chooses specific tracks for editing operations.

Lock Tracks
Prevents further changes to the selected track.

Auto Track Selector – Page 696
Automatically select tracks for editing operations.

Enable/Disable Video Tracks – Page 643
Shows or hides specific video tracks.

Output Blanking – Page 289
Sets letterboxing options.

Find Current Timeline in Media Pool – Page 396
Opens the bin in the media pool with the selected timeline, and highlights it.

Clip

New Compound Clip – Page 847
Makes a compound clip out of the selected clips.

New Fusion Clip – Page 1183
Makes a Fusion composition out of the selected clips.

New VFX Connect Clip – Page 1040
Links the current selection to the stand alone version of Fusion.

Open in Timeline – Page 853
Opens a nested timeline temporarily into its component pieces for editing.

Decompose in Place – Page 854
Breaks a nested timeline into its original component pieces.

Conform Lock Enabled – Page 1076
Locks clip references to a specific media file, preventing accidental changes.

Conform Lock with Media Pool Clip – Page 1076
Forces a clip to reference a specific media file selected in the Media Pool.

Link to Reference Composition – Page 1187
Adds a clip to a Reference Composition.

Create Reference Composition – Page 1185
Makes a Reference Composition from the selected clips.

Unlink Reference Composition – Page 1188
Removes the link to a Reference Composition from the selected clip.

Find Reference Composition in Media Pool – Page 1188
Locates the Reference Composition in the media pool.

Enable Clip – Page 716
Toggles a clip's visibility on or off.

Link Clips – Page 723
Toggles Link or Unlink for the selected clips.

Show Keyframe Editor – Page 1027
Opens a clip's keyframe editor for animating parameters.

Show Curve Editor – Page 1028
Opens the clip's curve editor for advanced keyframing

Change Clip Duration – Page 536
Opens the Change Clip Duration tools.

Change Clip Speed – Page 995
Opens the simple speed retiming controls.

Freeze Frame – Page 995
Creates a still frame for the duration of the selected clip using the frame under the playhead.

Retime Controls – Page 998
Opens the Retime Controls on the selected clip.

Reset Retime – Page 999
Resets the Retime Controls on a clip back to their original state.

Auto Align Clips – Page 758
Aligns clips on a timeline based on timecode or audio waveform.

Audio – Page 909
Opens a menu to change the audio volume of a clip.

Take Selector – Page 846
Creates a Take Selector from the selected clips.

Finalize Take – Page 847
Removes a Take Selector and uses the starred take.

Multicam Cut – Page 842
Cuts to another angle in a Multicam Clip.

Multicam Switch – Page 842
Changes to another angle in a Multicam Clip without cutting.

Render Cache Fusion Output – Page 200
Toggles the options for caching Fusion compositions in a timeline.

Render Cache Color Output – Page 201
Toggles the Render Cache on or off for Color operations in the timeline.

Find Clip in Media Pool – Page 832
Locates the selected clip in the Media Pool.

Match Frame to Source Clip – Page 830
Performs a Match Frame operation on the selected clip in the timeline.

Mark

Mark In – Page 689
Sets the In Point on a clip or timeline.

Mark Out – Page 689
Sets the Out Point on a clip or timeline.

Mark Video In – Page 690
Creates an in point for the video track of a split edit.

Mark Video Out – Page 690
Creates an out point for the video track of a split edit.

Mark Audio In – Page 690
Creates an in point for the audio tracks of a split edit.

Mark Audio Out – Page 690
Creates an out point for the audio tracks of a split edit.

Convert In and Out to Duration Marker – Page 676
Turns the in and out points into a duration marker.

Set In and Out from Duration Marker – Page 692
Turns a duration marker into In and Out Points.

Clear In – Page 691
Removes the In Point on a clip or timeline.

Clear Out – Page 691
Removes the Out Point on a clip or timeline.

Clear In and Out – Page 691
Removes both the In and Out Points on a clip or timeline.

Clear Video In and Out – Page 691
Clears the In and Out Points on the Video track for a split edit.

Clear Audio In and Out – Page 568
Clears the In and Out Points on the Audio tracks for a split edit.

Mark Clip – Page 773
Automatically sets In and Out Points based on a clip duration.

Mark Selection – Page 773
Automatically sets In and Out Points based on total duration of multiple clips.

Create SubClip – Page 448
Creates a subclip based on the In and Out points of a clip.

Keyframe Timeline Mode – Page 3134
Choose which keyframe types to copy between Color grades.

Add Keyframe – Page 3104
Adds a Dynamic Keyframe at the playhead position.

Add Static Keyframe – Page 3232
Adds a Static Keyframe at the playhead position.

Delete Keyframe
Removes a keyframe at the playhead position.

Delete All Keyframes
Removes all keyframes from a selected parameter.

Move Selected Keyframes Left
Moves all selected keyframes left by 1 frame.

Move Selected Keyframes Right
Moves all selected keyframes right by 1 frame.

Move Selected Keyframes Up
Moves all selected keyframes up by 1 unit.

Move Selected Keyframes Down
Moves all selected keyframes down by 1 unit.

Add Marker – Page 811
Adds a marker to a clip or timeline by color.

Add and Modify Marker – Page 919
Adds a marker to a clip or timeline, and opens the Marker properties dialog.

Modify Marker – Page 815
Opens the Marker properties dialog for the selected marker.

Delete Marker – Page 817
Deletes the selected Marker

Delete All Markers – Page 817
Deletes all markers on a clip or timeline, or by specific marker color.

Favorite Keywords – Page 342
Apply a favorite keyword to a clip from your list.

Add Flag – Page 810
Adds a flag to a clip by color.

Clear Flags – Page 676
Removes all flags from a selected clip.

Delete All Flags – Page 810
Removes all flags from all clips by color.

Set Clip Color – Page 825
Changes a clip's color in the timeline.

View

Bypass Color and Fusion – Page 630
Turns on or off Color and/or Fusion operations in a timeline.

Display Broadcast Safe Exceptions – Page 2816
Turns on the Broadcast Safe overlay.

Source/Timeline Viewer – Page 629
Toggles between making the Source or Timeline viewer active in the Edit page.

Source Clip/Source Tape – Page 525
Toggles between Source Clip and Source Tape in the Cut page viewer.

Zoom
Zoom options for the viewer.

Zoom Around Mouse Pointer – Page 669
Centers the timeline zoom on the pointer rather than the playhead in the Edit page.

Zoom Audio Waveform – Page 3513
Sets waveform zooming parameters in the Fairlight page.

Safe Area – Page 528
Toggles the safe area overlays for the Edit and Color pages.

Select Aspect Ratio – Page 2858
Selects the Aspect Ratio for the Safe Area overlay.

Switch Eye To – Page 326
Chose the current eye for Stereoscopic workflows.

Viewer Overlay – Page 991
Sets the Viewer On Screen controls in the Edit Page.

Show Duplicate Frames – Page 673
Duplicate clips are marked in the Edit page timeline.

Show File Names – Page 437
Toggles between displaying Clip names or File names in the Edit page.

Overlay Synced Audio File Names – Page 436
Shows the names of the original audio files in the Edit page.

Show Audio Track Layers – Page 3814
Reveals track layers in the Fairlight page.

Show Subtitle Regions – Page 1021
Shows or Hides regions in the subtitle tracks.

Timeline Thumbnail Mode – Page 2890
Toggles clip order between A or C mode in the Color page.

Timeline Thumbnail Info – Page 2887
Choose what clip info is shown on the thumbnail in the Color page.

Timeline Thumbnail Size – Page 2885
Chooses the size of the thumbnails in the Color page.

Show Current Clip With Handles – Page 2887
Shows the handles of a clip in the Color page.

Show Markers – Page 823
Shows or Hides markers based on color.

Show Flags – Page 811
Shows or Hides flags based on color.

Timeline Scrolling – Page 3520
Sets the timeline scrolling method in the Fairlight page.

Show Preview Marks – Page 774
Toggles Preview Marks on or off in the Edit page.

Enable Multiview Edit Preview – Page 863
Enables or disables the multi-frame displays in the Edit page.

Playback

Use Optimized Media if Available – Page 188
Toggles the use of Optimized Media or original media.

Proxy Handling – Page 209
Exposes a submenu to control how proxy media playback is handled.

Timeline Proxy Resolution – Page 190
Options for Timeline Proxy Mode playback.

Render Cache – Page 195
Options for using the Render Cache.

Delete Render Cache – Page 188
Options for Deleting the Render Cache.

Manage Render Cache – Page 202
Opens the Cache Manager.

Fusion Memory Cache – Page 200
Options for using the Fusion Cache.

Play Reverse – Page 682
Plays 100% backward.

Stop – Page 682
Stops playback.

Play Forward – Page 682
Plays 100% forward.

Pause/Start Playback – Page 682
Stops and Starts playback.

Play Again – Page 682
Restarts playback from the original position.

Stop and Go to Last Position – Page 684
Playhead returns to original position on stop.

Record – Page 3583
Initiates recording in the Fairlight Page.

Fast Reverse – Page 676
Plays in Fast Reverse.

Fast Forward – Page 682
Plays in Fast Forward.

Play Slow – Page 683
Plays forward in Slow Motion.

Fast Review – Page 637
Initiates the Fast Review function.

Loop/Unloop – Page 684
Toggles Looping playback on or off.

Play Around/To – Page 684
Options for choosing the Play Around/To mode.

Timecode – Page 685
Options to increment or decrement timecode.

Go To – Page 691
Options to move the playhead directly to a certain location.

Step One – Page 682
Move forward or backward one frame or one second.

Previous
Moves playhead to the previous Clip, Keyframe, Marker or Gap.

Next
Moves playhead to the next Clip, Keyframe, Marker or Gap.

Jump Left – Page 3586
Moves clip selection left in the Fairlight page.

Jump Right – Page 3586
Moves clip selection right in the Fairlight page.

Cintel Scanner – Page 467
Transport controls for the Cintel Scanner.

Fusion

Show Toolbar – Page 1154
Toggles the Fusion toolbar on or off.

Fusion Settings – Page 1177
Opens the Fusion Settings window.

Reset Composition
Resets a Fusion composition to its initial state.

Macro Editor – Page 1283
Opens the Macro Editor.

Import
Specific file format import for Fusion.

- **Alembic Scene** – Page 1779
- **FBX Scene** – Page 1725
- **PSD** – Page 1205
- **Shapes** – Page 1201
- **SVG** – Page 1201
- **Tracks** – Page 1201

Render All Savers – Page 1212
Renders OpenEXR files.

Color

Nodes – Page 3164
Opens a menu for various node operations.

Reset – Page 3163
Options for resetting a Node.

Grade Version – Page 3121
Opens a menu for clip Version operations.

Stills
Opens a menu for manipulating stills in the Gallery

- **Grab Still** – Page 3105
- **Play Still** – Page 2861
- **Previous Still** – Page 3108
- **Next Still** – Page 3108

Apply Grade – Page 3135
Applies a grade to the selected clips.

Apply Active Layer – Page 3170
Applies the current Node Stack Layer to the grade.

Append Node Graph – Page 3137
Appends a node graph to the end of the current node tree.

Step Timeline Wipe – Page 3155
Moves the selected wipe timeline clip forward one frame.

Preview Memory – Page 3163
Preview a saved grade on the current clip.

Original Memory – Page 3163
Reverts to a grade's original state.

Memories – Page 3118
Load and Save Memories.

Apply Grade From One Clip Prior – Page 3135
Copies a grade from one clip back.

Apply Grade From Two Clips Prior – Page 3135
Copies a grade from two clips back.

Presets – Page 3025
Accesses HSL Qualifier color presets.

Ripple Node Changes to Selected Clips – Page 3143
Copies changes made in a node to a selected clips.

Ripple Node Changes to Current Group – Page 3144
Copies changes made in a node to a group.

Append Node to Selected Clips – Page 3144
Appends the selected node to multiple clips.

Auto Color – Page 2907
Performs an Auto Color operation.

Active Playhead – Page 2887
Choses the Active Playhead.

Tracker – Page 3079
Basic Tracker controls.

Resolve Live – Page 307
Opens the Resolve Live interface.

Printer Light Hotkeys – Page 2937
Activates Printer Light controls on the numerical keypad.

Full Printer Light – Page 2936
Adjust printer lights in Full increments.

Half Printer Light – Page 2937
Adjust printer lights in Half increments.

Quarter Printer Light – Page 2937
Adjust printer lights in Quarter increments.

Dolby Vision® – Page 254
Performs an automatic Dolby Vision trim analysis.

HDR10+ – Page 271
Performs an automatic HDR10+ trim analysis.

HDR Vivid – Page 272
Performs an automatic HDR Vivid trim analysis.

Automatically Link AMF for – Page 246
Choose Selected or All shots to link an ACES AMF file to.

Fairlight

Bus Format – Page 3570
Opens the Bus Format window where you can create mono to multi-channel Atmos buses.

Bus Assign – Page 3573
Opens the Bus Assign window where you can patch buses to tracks, tracks to buses and buses to buses.

Presets Library – Page 657
Opens the Presets Library allowing you to choose saved Preset Configurations for EQ, Dynamics, Plugins, Global Track, Global Bus and Fairlight Configurations.

Link Group – Page 3567
Opens the Link Group window allowing you to link groups of tracks.

VCA Assign – Page 3711
Opens the VCA Assign window allowing you to assign VCA groups to specific tracks.

Patch Input/Output – Page 3574
Opens the Patch Input/Output window allowing you to patch Source to Destination routings.

Test Tones Settings – Page 3553
Opens the Test Tones Settings window with the Oscillator for creating various signal tones.

Remote Control Settings
Opens the SMPTE timecode settings in the Fairlight page.

Input Monitor Style – Page 3595
Allows you to choose how to monitor an input.

Monitoring – Page 3799
Allows you to change the Global monitoring between Mute, Dim, and Mono.

Exclusive Solo – Page 3714
When selected takes all other soloed tracks out of solo mode.

Immersive Audio
Exposes the following immersive audio tools.

- **B-Chain Control** – Page 3831
- **Space View Scope** – Page 3836
- **Import Master - import ADM files** – Page 3816
- **Export Master - export ADM files** – Page 3816
- **Renderer Settings** – Page 3816

Automation – Page 3721
Lists the Fairlight automation options.

Batch Fade Settings – Page 3644
Opens the Batch Fade Settings window to set fade types and durations.

Apply Batch Fades – Page 3644
Applies the fades set in the Batch Fade Settings window.

View Clip Info Display – Page 3523
Opens the Clip Info Display window.

Show Clip Gain Line – Page 3669
Shows or hides the Clip Gain Line in clips on the timeline.

Workspace

Switch to Page – Page 21
Switches to the selected page.

Show Page – Page 16
Shows or hides specific pages.

Show Page Navigation – Page 21
Disables page navigation icons in the GUI.

Show Panel in Workspace – Page 58
Shows or hides specific panels.

Active Panel Selection – Page 56
Switches to the selected panel.

Media Pool Windows – Page 389
